A B S T R A C T

Background

Human milk banking has been available in many countries for the last three decades. The milk provided from milk banking is predominantly term breast milk, but some milk banks provide preterm breast milk. There are a number of differences between donor term and donor preterm human milk.

Objectives

To determine the effect of banked donor preterm milk compared with banked donor term milk regarding growth and developmental outcomes in very low birth weight infants (infants weighing less than 1500 grams).

Search methods

We used the standard search strategy of Cochrane Neonatal to search the Cochrane Central Register of Controlled Trials (CENTRAL 2018, Issue 7), MEDLINE via PubMed (1966 to 23 October 2018), Embase (1980 to 23 October 2018), and CINAHL (1982 to 23 October 2018). We also searched clinical trial databases, conference proceedings, and the reference lists of retrieved articles for randomised controlled trials and quasi-randomised trials**.**

Selection criteria

Randomised and quasi-randomised trials comparing banked donor preterm milk with banked donor term milk regarding growth and developmental outcomes in very low birth weight infants

Data collection and analysis

We planned to perform assessment of methodology regarding blinding of randomisation, intervention and outcome measurements as well as completeness of follow-up. We planned to evaluate treatment effect using a fixed-effect model using relative risk (RR), relative risk reduction, risk difference (RD) and number needed to treat for an additional beneficial outcome (NNTB) or the number needed to treat for an additional harmful outcome (NNTH) for categorical data; and using mean, standard deviation and weighted mean difference (WMD) for continuous data. We planned to use the GRADE approach to assess the quality of evidence.

Main results

No studies met the inclusion criteria.

Authors' conclusions

We found no evidence to support or refute the effect of banked donor preterm milk compared to banked term milk regarding growth and developmental outcomes in very low birth weight infants.

P L A I N   L A N G U A G E   S U M M A R Y

Banked preterm versus banked term human milk to promote growth and development in very low birth weight infants

Review question

When mother's own milk is not available or is insufficient, does feeding banked donor preterm milk compared to banked donor term milk result in improved growth and neurodevelopmental outcome in very low birthweight infants?

Background

Donor-expressed milk processed by human milk banks has been used to provide preterm infants with breast milk when there are circumstances that preclude the use of mother's own milk. Preterm milk differs significantly from term breast milk. The processes involved in providing donor milk, including freezing, thawing and pasteurisation has adverse effects on nutritional and non-nutritional aspects of donor milk. Donor milk is expensive. We wished to determine whether the benefits of preterm donor milk were superior to term donor milk either as a sole diet, or as a supplement to mother's own milk.

Study characteristics

We were unable to identify any studies that compared donor preterm milk with donor term milk to promote growth and development in very low birth weight infants. Evidence is up to date as of October 2018.

Key results

We were unable to conclude that donor preterm milk was superior to term donor milk as there is no evidence to support or refute this question. However the lack of studies identified in the original review and now updated in this review means that it is extremely unlikely that any such study will be performed.

Quality of evidence

There were no studies to make an assessment of quality of evidence.

Banked preterm versus banked term human milk to promote growth and development in very low birth weight infants (Review)

2

BACKGROUND

Description of the condition

Mother's own milk is the milk of choice when feeding the preterm very low birth weight infant. Human milk provides a variety of benefits compared to formula. In preterm infants, reported benefits include faster gastric emptying (Cavell 1981; Ewer 1994), faster attainment of full enteral feeding (Uraizee 1989; Lucas 1990), enhanced stimulation of gastrointestinal motility and improved intestinal growth and maturation (Sheard 1988; Groer 1996). Breast milk is associated with a reduction in the incidence of necrotising enterocolitis (NEC) and late-onset sepsis (Narayanan 1984; Schanler 1999). Preterm infants fed human milk appear to have improved neurodevelopmental outcome compared with infants fed formula milk (Anderson 1999). This association has been supported in the extremely low birth weight (ELBW) infant (Vohr 2006). Neonates fed breast milk tend to have improved visual development with less retinopathy of prematurity (Hylander 1995). However, there are circumstances when mother's breast milk may not be available. These circumstances occur when mothers cannot provide their own milk due to illness, inability to produce breast milk or due to concerns regarding certain prescription medications.

Description of the intervention

Human milk banking has been available in many countries for the last three decades and has played an important role in neonatal care. There are a number of donor milk banks in North America, United Kingdom, Europe and Australia. Human milk is donated to the milk bank voluntarily. Donors are screened for HIV, hepatitis B and C, human T-lymphotropic virus and syphilis (Gibbins 2013). There has been a significant growth in the number of milk banks internationally. The screening, processing and shipping of donor breast milk incur considerable costs. The cost per ounce of expressed milk supplied to institutions varies from country to country. In the USA the estimated cost is USD 3 per ounce; in the UK it is GBP 3 per ounce, including processing and shipping costs (Arnold 2002).

Donor-expressed milk has been used to provide preterm infants with breast milk when circumstances otherwise preclude the use of mother's own milk. Exclusive feeding with donor breast milk has been shown to reduce the incidence of NEC when compared to formula (McGuire 2003; Boyd 2006), but growth was slower. This benefit was only seen when breast milk was the sole dietary source. Some studies using donor-banked milk or formula as a supplement to mother's own milk did not find any significant differences in reduction of NEC (Lucas 1984; Schanler 2005). There appears to be no evidence supporting enhanced long-term outcome in infants fed donor milk (Modi 2006; Quigley 2018).

How the intervention might work

The milk provided from milk banking is predominantly term breast milk (often produced later in lactation so it has a different nutrient content), although many breast milk banking services now also batch and provide donated preterm breast milk (Tully 2001; Wight 2001). There are a number of differences between term and preterm human milk (Gidrewicz 2014). The nutritional and non-nutritional components of human milk differ as gestational age advances (Boyce 2016). The relative constituents of protein, fat and carbohydrate differ (Gross 1980; Butte 1984), as do the non-nutritional components including variations in digestive hormones, growth factors, immunological factors, vitamins, minerals and trace elements (Schanler 1980; Saarela 2005). Gidrewicz highlighted a preterm milk protein content of 2.2 g/dL and a fat content of 2.6 g/dL compared to term milk protein content of 1.8 g/dL and a fat content of 2.2 g/dL in the first week of life (Gidrewicz 2014). Long chain polyunsaturated fatty acids (LCPUFA) found in both term and preterm milk may differ. LCPUFA play an important role in optimal brain development and retinal maturation (Genzel-Boroviczeny 1997). Donor breast milk undergoes a number of different processes including freezing and pasteurisation. These processes alter the nutritional composition of the milk and may affect preterm donor milk in a different way to term donor milk. Pasteurisation affects nutritional components resulting in slightly slower growth of infants on donor breast milk compared to raw unpasteurized human milk (Stein 1986). Pasteurisation affects immunological factors resulting in lower levels of lactoferrin and IgG. It eliminates white blood cells and bacteria. Despite pasteurisation IgA, bifid growth factor and lysozyme remain intact (Ford 1977). Holder pasteurisation (62.5 °C for 30 minutes) seems to be superior to heat treatment at 56 °C for 30 minutes in terms of cytomegalovirus elimination (Evans 1978). Freezing will eliminate most viruses and does not appear to influence nutritional quality of the milk (Wight 2001). Freezing does reduce the concentration of lysozyme by up to 20%, and also destroys all white blood cells. Microwaving affects the milk in the same way as described with pasteurisation (Quan 1992). Other newer methods of pasteurisation may have different effects on donor milk composition.

Why it is important to do this review

The inherent nutritional and non-nutritional components of preterm and term donor milk differ (Gidrewicz 2014). The effects of freezing and pasteurisation alter the composition of donor milk, and may alter preterm and term donor milk differently. Therefore, the effect of banked donor preterm milk compared to donor term milk in feeding the very low birthweight infant warrants further investigation.

OBJECTIVES

To determine the effect of banked donor preterm milk compared with banked donor term milk regarding growth and developmental outcomes in very low birth weight infants (infants weighing less than 1500 grams).

The following comparisons were planned.

1. Any banked donor preterm milk (with or without fortification) versus any banked donor term milk (with or without fortification)
2. Banked donor preterm milk (with or without fortification) versus banked donor term milk (with or without fortification) where both were used as sole enteral diet
3. Any banked donor preterm milk (with or without fortification) versus any banked donor term milk (with or without fortification) in the extremely low birth weight infant

METHODS

Criteria for considering studies for this review

Types of studies

Trials using randomisation or quasi-randomisation of patients were eligible for inclusion. Published or unpublished studies were eligible for inclusion. We would have included unpublished studies or studies published only as abstracts if assessment of study quality was possible and if other criteria for inclusion were fulfilled.

Types of participants

Very low birth weight infants (infants weighing less than 1500 grams) fed donor banked human milk. Infants receiving partial enteral feeding (formula or mother's own milk) at study entry were eligible.

Types of interventions

Use of banked donor preterm milk versus banked donor term milk with or without fortification fed either as a sole enteral diet or as a supplement to mother's own milk.

Types of outcome measures

Primary outcomes

1. Short-term growth parameters: time to regain birth weight (days of life), weight gain (grams/day), length gain (centimetres/week), head growth (centimetres/week) at discharge;
2. Longer-term growth parameters (following discharge from hospital): weight gain (grams/week), length gain (centimetres/week), head growth (centimetres/week) at four months' follow-up;
3. Neurodevelopmental outcomes at term corrected age and at 18 to 24 months using validated assessment tools.

Secondary outcomes

1. Incidence of necrotising enterocolitis (defined as Bell's Stage 2 or greater);
2. Incidence of late onset sepsis;
3. Duration of total parenteral nutrition use (days);
4. Time to full enteral feeds (days);
5. Feeding intolerance defined as abdominal distension with large gastric residuals (> 50% of previous feed).

Search methods for identification of studies

We used the standard search strategy of Cochrane Neonatal.

Electronic searches

We conducted a comprehensive search including the Cochrane Central Register of Controlled Trials (CENTRAL 2018, Issue 7 in the Cochrane Library), MEDLINE via PubMed (1966 to 23 October 2018), Embase (1980 to 23 October 2018) and CINAHL (1982 to 23 October 2018) using the search terms detailed in Appendix 1. We did not apply language restrictions. This search was an update of the searches run for the review first published in 2010 (see Appendix 2 for previous search details) (Dempsey 2010).

We searched clinical trial registries for ongoing or recently completed trials (clinicaltrials.gov; the World Health Organization's International Trials Registry and Platform www.whoint/ictrp/search/en; and the ISRCTN Registry) on 23 October 2018.

Searching other resources

Other searches included reference lists of all selected articles as well as review articles. We also searched unpublished, in press and in progress trials and abstracts from neonatal and paediatric meetings. This included the proceedings of the Pediatric Academic Society meetings (PAS electronic version from 2000 to 2018) and the European Society for Paediatric Research meetings (from 2000 to 2018). Trials reported only as abstracts were considered eligible if there was sufficient information available from the report or from contact with the authors.

Data collection and analysis

We used the standard methods of Cochrane Neonatal.

Selection of studies

We applied machine learning using the Cochrane Classifier tool in the Cochrane Register of Studies (CRS) to assess, then remove, reports with the least (0% to 2%) probability of being randomised controlled trials and with the least (0% to 2%) probability of having infants in the population. Each review author independently searched for trials and selected studies for inclusion with comparison and resolution of any differences. We illustrate our findings in a flowchart (Figure 1).

### Data extraction and management

If eligible trials had been identified, each review author planned to independently extract the data and compare results. We planned to use a data collection form to aid extraction of information on design, methodology, participants, intervention outcomes and treatment effects from included studies. We planned to resolve any disagreements through discussion.

Assessment of risk of bias in included studies

The two review authors planned to independently assess the risk of bias (low, high, or unclear) of all included trials using the Cochrane 'Risk of bias' tool, as described in Higgins 2017, for the following domains.

- Sequence generation (selection bias)
- Allocation concealment (selection bias)
- Blinding of participants and personnel (performance bias)
- Blinding of outcome assessment (detection bias)
- Incomplete outcome data (attrition bias)
- Selective reporting (reporting bias)
- Any other bias

We planned to resolve any disagreements by discussion or by inviting a third assessor to arbitrate. See Appendix 3 for a more detailed description of risk of bias for each domain.

Measures of treatment effect

We planned to evaluate categorical data by calculating the relative risk (RR), relative risk reduction, risk difference (RD) and number needed to treat for an additional beneficial outcome (NNTB) or the number needed to treat for an additional harmful outcome (NNTH). We intended to obtain mean and standard deviation for continuous data and perform analysis using the weighted mean difference (WMD). For each measure of effect, we planned to calculate the 95% confidence interval.

Unit of analysis issues

Our planned unit of analysis was the participating infant in individually randomised controlled trials.

Dealing with missing data

Where data were missing, we planned to deal with this by firstly contacting the relevant author. If we assumed that the data were missing at random, we planned to analyse the data without imputing any missing data.

Assessment of heterogeneity

We planned to examine heterogeneity between trials by inspecting the forest plots and quantifying the impact of heterogeneity using the I^2 statistic. If we detected statistical heterogeneity ($I^2 > 50\%$) we planned to explore the possible causes (for example, differences in study quality, participants, intervention regimens, or outcome assessments) using post hoc subgroup analyses.

Assessment of reporting biases

We planned to examine a funnel plot for asymmetry if there were more than 10 included trials.

Data synthesis

If we had identified multiple studies and judged that meta-analysis was appropriate, we would have performed the analysis using Cochrane's Review Manager 5 software (Review Manager 2014). For estimates of typical relative risk and risk difference, we planned to use the Mantel-Haenszel method. For measured quantities, we planned to use the inverse variance method. We intended to conduct all meta-analyses using the fixed-effect model.

Quality of evidence

We planned to use the GRADE approach, as outlined in the GRADE Handbook (Schünemann 2013), to assess the quality of evidence for the following (clinically relevant) outcomes: growth, neurodevelopmental outcome, NEC and sepsis.

Review authors planned to independently assess the quality of the evidence for each of the outcomes above. We planned to consider evidence from randomised controlled trials as high quality but to downgrade the evidence one level for serious (or two levels for very serious) limitations based upon the following: design (risk of bias), consistency across studies, directness of the evidence, precision of estimates and presence of publication bias. We planned to use the GRADEpro GDT Guideline Development Tool to create a 'Summary of findings' table to report the quality of the evidence (GRADEpro GDT).

The GRADE approach results in an assessment of the quality of a body of evidence in one of the following four grades.

1. High: we are very confident that the true effect lies close to that of the estimate of the effect.
2. Moderate: we are moderately confident in the effect estimate: the true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different.

Banked preterm versus banked term human milk to promote growth and development in very low birth weight infants (Review)

Copyright © 2019 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

6

3. Low: our confidence in the effect estimate is limited: the true effect may be substantially different from the estimate of the effect.

4. Very low: we have very little confidence in the effect estimate: the true effect is likely to be substantially different from the estimate of effect.

Subgroup analysis and investigation of heterogeneity

The primary objective was to compare any banked preterm donor milk (with or without fortification) to any banked term donor milk (with or without fortification).

Subgroup comparisons of preterm donor milk with fortification to banked term donor milk with fortification and preterm donor milk without fortification to banked term donor milk without fortification were planned as following for each comparison.

Any banked donor preterm milk (with or without fortification) versus any banked donor term milk (with or without fortification)

The following subgroups were planned.

1. Banked preterm milk with fortification (using multi-component breast milk fortifier) versus banked term milk with fortification (using multi-component breast milk fortifier).
2. Banked preterm milk without fortification versus banked term milk without fortification.

Banked donor preterm milk (with or without fortification) versus banked donor term milk (with or without fortification) where both were used as sole enteral diet

The following subgroups were planned.

1. Banked donor preterm milk with fortification versus any banked donor term milk with fortification where both were used as sole enteral diet.
2. Any banked donor preterm milk without fortification versus any banked donor term milk without fortification where both were used as sole enteral diet.

Any banked donor preterm milk (with or without fortification) versus any banked donor term milk (with or without fortification) in the extremely low birth weight infant

The following subgroups were planned.

1. Any banked donor preterm milk with fortification versus any banked donor term milk with fortification in the extremely low birth weight infant.
2. Any banked donor preterm milk without fortification versus any banked donor term milk without fortification in the extremely low birth weight infant.

Sensitivity analysis

There was no planned sensitivity analysis.

Description of studies

Please see Figure 1 outlining the results of the search.

Results of the search

Please see Figure 1 outlining the results of the search.

Included studies

There were no new studies identified for inclusion in this review.

Excluded studies

See Characteristics of excluded studies table. A number of randomised clinical trials studies compared donor breast milk with formula (Gross 1983; Tyson 1983; Lucas 1990; Schanler 2005; Cristafolo 2013; Corpelejin 2016; O'Connor 2016); and some of these were the subject of a series of systematic reviews (McGuire 2003; Quigley 2007; Quigley 2014; Quigley 2018). None, however, compared donor preterm milk with donor term milk. One study compared pooled pasteurised breast milk with untreated mother's own milk but did not compare donor preterm milk with donor term milk (Stein 1986). Another study compared pooled pasteurised breast milk with untreated mother's own milk but again did not compare donor preterm versus term milk; it was also a before-after study (Montjaux-Régis 2011).

Risk of bias in included studies

No studies met the inclusion criteria.

Allocation

No studies met the inclusion criteria.

Blinding

No studies met the inclusion criteria.

Incomplete outcome data

No studies met the inclusion criteria.

Selective reporting

No studies met the inclusion criteria.

Other potential sources of bias

No studies met the inclusion criteria.

Effects of interventions

No studies met the inclusion criteria.

D I S C U S S I O N

We found no randomised controlled trials comparing banked preterm breast milk with banked term breast milk in the very low birth weight infant; therefore, this systematic review did not establish whether preterm donor milk conferred any health benefits compared to term donor milk fed solely, or as part of, the overall enteral diet of the very low birth weight infant. There have been a number of more recent studies comparing donor milk to formula for feeding the preterm infant and these have been the subject of a recent systematic review (Quigley 2018). This review highlighted reduction in NEC, but lower rates of weight gain, linear growth, and head growth in the donor milk group. There was no difference in all-cause mortality or long-term outcome in this systematic review.

Banked preterm versus banked term human milk to promote growth and development in very low birth weight infants (Review)

Copyright © 2019 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

7

Each of these studies used pooled pasteurised breast milk, a combination of both preterm and (predominantly) term donor milk and so it is not possible to determine whether preterm donor milk had a greater influence on outcome compared with term donor milk. It is biologically plausible that preterm donor milk may confer additional benefits to the preterm infant compared to term donor milk because the nutritional components differ significantly. The non-nutritional components also differ, including variations in digestive hormones, growth factors, immunological factors, vitamins, minerals and trace elements, all of which may contribute to improved well-being in the preterm infant.

The lack of included studies since the previous review and the lack of any current registered clinical trials highlight that it is unlikely that there would be any future randomised controlled trials comparing preterm donor milk with term donor milk, where each is the sole agent used. The most obvious reason is because of a very limited supply of donated preterm milk to milk banks. The vast majority of donors are from mothers who have delivered full-term and have a large milk supply. Thus the limited supply of preterm donor milk, either because of limited donated volumes or limited numbers of breast milk banks that supply pooled preterm donor breast milk, means performing such studies would be difficult. Future randomised controlled trials could potentially be performed comparing preterm with term banked breast milk as an adjunct to mother's own milk or as an adjunct to formula feeding in the very low birth weight infant. However the same limitations would apply as highlighted above, which make it extremely unlikely that any such trial would be performed. It is more likely that future studies would focus on optimisation of the pooled undifferentiated donor milk content in the form of individualized fortification regimes.

Summary of main results

No included studies

Overall completeness and applicability of evidence

No included studies

Quality of the evidence

No included studies

Potential biases in the review process

No potential biases identified

Agreements and disagreements with other studies or reviews

This is an update of the previous review. This review again identified no new studies.

AUTHORS' CONCLUSIONS

Implications for practice

In this most recent update, again we found no randomised controlled trials that compared banked preterm milk versus banked term milk to promote growth and development in very low birth weight infants.

Implications for research

Although it is biologically plausible that banked preterm milk may be more suitable than banked term milk in feeding the preterm infant, it is unlikely that there would be any future randomised controlled trials comparing either milk source as a sole agent or an adjunct to mother's own milk or formula feeding. It is more likely that future studies would focus on optimisation of pooled undifferentiated donor milk in very low birth weight infants via different milk fortification methods.

ACKNOWLEDGEMENTS

The Methods section of this review is based on a standard template used by Cochrane Neonatal. We would like to sincerely thank Ms Colleen Ovelman for her support in performing this review.

CHARACTERISTICS OF STUDIES

Characteristics of excluded studies *[ordered by study ID]*

Study	Reason for exclusion
Corpelejin 2016	This study compared donor milk to formula.
Cristafolo 2013	This study compared donor milk to formula.
Gross 1983	This study compared human milk with formula.
McGuire 2003	This was a systematic review of donor breast milk compared to formula.
Montjaux-Régis 2011	This study compared pooled pasteurised breast milk with that of untreated mother's own milk and was a 'pre-post' study.
O'Connor 2016	This study compared donor milk to formula
Quigley 2007	This was a systematic review of donor breast milk compared to formula.
Quigley 2014	This was a systematic review of donor breast milk compared to formula.
Quigley 2018	This was a systematic review of donor breast milk compared to formula.
Schanler 2005	This study compared donor human milk versus preterm formula as an adjunct to mother's own milk.
Stein 1986	This study compared pooled pasteurised breast milk with untreated mother's own milk.
Tyson 1983	This trial compared pooled bank milk with enriched formula.

Banked preterm versus banked term human milk to promote growth and development in very low birth weight infants (Review)

12

Appendix 2. Previous search details

For the review published in 2010, electronic searches included a search of the Cochrane Neonatal Group specialized register and the Cochrane Central Register of Controlled Trials (CENTRAL, *The Cochrane Library*, January 2010). We identified relevant studies by searching the following: (1) computerised bibliographic databases: MEDLINE (1966 to February 2010), EMBASE (1988 to February 2010) and Web of Science (1975 to February 2010); (2) the Oxford Database of Perinatal Trials. The electronic search included the following keywords "donor expressed milk", "banked expressed milk" and MeSH search terms "Infant, Newborn" AND "Milk, Human" AND "Milk Banks". We limited trials to clinical trials where 'limits' option was available. We applied no language restrictions.

Appendix 3. 'Risk of bias' tool

We planned to use the standard methods of Cochrane and Cochrane Neonatal to assess the methodological quality of the trials. For each trial, we planned to seek information regarding the method of randomisation, blinding and reporting of all outcomes of all the infants enrolled in the trial. We planned to assess each criterion as being at a low, high, or unclear risk of bias. Two review authors planned to separately assess each study. We planned to resolve any disagreement by discussion. We planned to add this information to the table 'Characteristics of included studies'. We planned to evaluate the following issues and enter the findings into the 'Risk of bias' table.

1. Sequence generation (checking for possible selection bias). Was the allocation sequence adequately generated?

For each included study, we planned to categorize the method used to generate the allocation sequence as:

- low risk (any truly random process e.g. random number table; computer random number generator);
- high risk (any non-random process e.g. odd or even date of birth; hospital or clinic record number); or
- unclear risk.

2. Allocation concealment (checking for possible selection bias). Was allocation adequately concealed?

For each included study, we planned to categorize the method used to conceal the allocation sequence as:

- low risk (e.g. telephone or central randomisation; consecutively numbered sealed opaque envelopes);
- high risk (open random allocation; unsealed or non-opaque envelopes, alternation; date of birth); or
- unclear risk

3. Blinding of participants and personnel (checking for possible performance bias). Was knowledge of the allocated intervention adequately prevented during the study?

For each included study, we planned to categorize the methods used to blind study participants and personnel from knowledge of which intervention a participant received. Blinding was planned to be assessed separately for different outcomes or class of outcomes. We planned to categorize the methods as:

- low risk, high risk or unclear risk for participants; and
- low risk, high risk or unclear risk for personnel.

4. Blinding of outcome assessment (checking for possible detection bias). Was knowledge of the allocated intervention adequately prevented at the time of outcome assessment?

For each included study, we planned to categorize the methods used to blind outcome assessment. Blinding was planned to be assessed separately for different outcomes or class of outcomes. We planned to categorize the methods as:

- low risk for outcome assessors;
- high risk for outcome assessors; or
- unclear risk for outcome assessors.

5. Incomplete outcome data (checking for possible attrition bias through withdrawals, dropouts, protocol deviations). Were incomplete outcome data adequately addressed?

For each included study and for each outcome, we planned to describe the completeness of data including attrition and exclusions from the analysis. We planned to note whether attrition and exclusions were reported, the numbers included in the analysis at each stage (compared with the total randomised participants), reasons for attrition or exclusion where reported, and whether missing data were balanced across groups or were related to outcomes. Where sufficient information was reported or supplied by the trial authors, we planned to re-include missing data in the analyses. We planned to categorize the methods as:

- low risk (< 20% missing data);
- high risk (≥ 20% missing data); or

Banked preterm versus banked term human milk to promote growth and development in very low birth weight infants (Review)

Copyright © 2019 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

13

- unclear risk.

6. Selective reporting bias. Are reports of the study free of suggestion of selective outcome reporting?

For each included study, we planned to describe how we investigated the possibility of selective outcome reporting bias and what we found. For studies in which study protocols were published in advance, we planned to compare prespecified outcomes versus outcomes eventually reported in the published results. If the study protocol was not published in advance, we planned to contact study authors to gain access to the study protocol. We planned to assess the methods as:

- low risk (where it is clear that all of the study's prespecified outcomes and all expected outcomes of interest to the review have been reported);
- high risk (where not all the study's prespecified outcomes have been reported; one or more reported primary outcomes were not prespecified outcomes of interest and are reported incompletely and so cannot be used; study fails to include results of a key outcome that would have been expected to have been reported); or
- unclear risk.

7. Other sources of bias. Was the study apparently free of other problems that could put it at a high risk of bias?

For each included study, we planned to describe any important concerns we had about other possible sources of bias (for example, whether there was a potential source of bias related to the specific study design or whether the trial was stopped early due to some data-dependent process). We planned to assess whether each study was free of other problems that could put it at risk of bias as:

- low risk;
- high risk;
- unclear risk.

If needed, we planned to explore the impact of the level of bias through undertaking sensitivity analyses.

WHAT'S NEW

Date	Event	Description
8 July 2020	Amended	Typo in Declarations of interest section corrected

HISTORY

Protocol first published: Issue 1, 2009
Review first published: Issue 6, 2010

Date	Event	Description
4 June 2019	New citation required but conclusions have not changed	No new studies were found.
23 April 2019	New search has been performed	Updated review of Dempsey 2010.

CONTRIBUTIONS OF AUTHORS

Dr. Dempsey conceived and designed the review.
Both review authors performed separate data collection for the review.

DECLARATIONS OF INTEREST

ED has no interest to declare.

JM has not literest to declare.

Banked preterm versus banked term human milk to promote growth and development in very low birth weight infants (Review)
