30 **Abstract**

31 Despite decades of research on per- and polyfluoroalkyl substances (PFAS), fundamental obstacles  
32 remain to addressing worldwide contamination by these chemicals and their associated impacts on  
33 environmental quality and health. Here we propose six urgent questions relevant to science, technology,  
34 and policy that must be tackled in order to address the “PFAS problem”: (1) What are the global  
35 production volumes of PFAS, and where are PFAS used? (2) Where are the unknown PFAS hotspots in  
36 the environment? (3) How can we make the measurement of PFAS globally accessible? (4) How can we  
37 safely manage PFAS-containing waste? (5) How do we understand and describe the health effects of  
38 PFAS exposure? And (6) Who pays the costs of PFAS contamination? The importance of each question  
39 and barriers to progress are briefly described, and several potential paths forward are proposed. Given the  
40 diversity of PFAS and their uses, the extreme persistence of most PFAS, the striking ongoing lack of  
41 fundamental information, and the inequity of the health and environmental impacts from PFAS

42 contamination, there is a need for scientific and regulatory communities to work together, with  
43 cooperation from PFAS-related industries, to fill in critical data gaps and protect human health and the  
44 environment.

45  
46 **Synopsis:** This article discusses key gaps in data, understanding, and technology to address the problem  
47 of global PFAS contamination, identifies persistent barriers, and suggests useful paths forward.

48  
49 **Introduction**

50 Per- and polyfluoroalkyl substances (PFAS) are a class of thousands of chemicals<sup>1-3</sup> with perfluorinated  
51 carbon moieties that impart physical stability, chemical resistance, and, for most PFAS, extreme  
52 environmental persistence<sup>4</sup>. For decades, PFAS have been incorporated into a vast array of products and  
53 applications,<sup>5</sup> and as a result, are pervasive environmental contaminants<sup>6,7</sup>. The beginning of the 21st  
54 Century saw increasing detection of long-chain perfluoroalkyl acids (PFAAs) in the environment and  
55 organisms on a global scale. Recognition that some of these chemicals are globally transported,  
56 bioaccumulate, and exert multiple adverse effects in biological systems led to regulation and phase-out of  
57 several PFAS<sup>8-11</sup>. In response, an array of other PFAS have been used as substitutes and are increasingly  
58 detected in the environment, in wildlife, and in humans<sup>12-16</sup>.

59  
60 Despite two decades of research on fate and transport, biological effects, and environmental emissions,  
61 critical gaps remain in our knowledge, preventing researchers and society from finding effective solutions  
62 to the “PFAS problem”. This is due to the diversity of chemicals in the PFAS class, to ongoing analytical  
63 challenges in detecting, characterizing, and quantifying different PFAS, and to a continued lack of  
64 transparency on the part of industry concerning which PFAS are produced, where they are used, and in  
65 what quantities. As society grapples with how PFAS may best be regulated and how to prioritize efforts  
66 to minimize environmental and human exposure, major challenges remain. Here, we identify a set of six  
67 urgent questions that must be addressed for the effective global management and eventual phase-out of

68 PFAS (Figure 1), building on the Zurich Statement on Future Actions on PFAS<sup>17</sup>. We also highlight  
69 major barriers that impede progress in answering these questions, and provide potential paths forward  
70 from the perspectives of science, technology, and policy.

71

72

73 **Figure 1:** Six urgent questions relevant to science, technology, and policy that must be tackled in order to  
74 address the “PFAS problem”.

75

76 **1. What are the global production volumes of PFAS, and where are PFAS used?**

77 **Importance:** This deceptively simple question highlights a fundamental gap in society’s knowledge about

nearly all PFAS. Despite painstaking emission estimates for the best-characterized sub-classes of PFAS<sup>18,19</sup>, there is a lack of information on historical and ongoing production volumes of most PFAS, including even their identities<sup>1,20,21</sup>. This information is needed to build reliable emissions inventories, investigate

82 environmental fate and transport, and assess associated exposures and health risks. While this is a general

83 problem for most chemicals in commerce<sup>22</sup>, the multitude of uses for PFAS and the transformation of

84 various precursors into the same PFAS end-products make tracking the sources of PFAS exposure to

85 production and use particularly difficult. Without these data, society will fail to protect its members from  
86 unknown exposures until or even after harmful and irreversible effects are discovered.

87

88 **Barriers:** Regulatory bodies in many countries have developed registries of chemicals produced or used  
89 in their jurisdictions<sup>18,19,22–24</sup>, but much of the collected information is confidential. In addition, many  
90 newer uses of PFAS remain poorly documented in the technical literature. The Kirk-Othmer  
91 Encyclopedia of Chemical Technology (2004)<sup>25</sup> and Kissa (2001)<sup>26</sup> are considered authoritative reference  
92 sources for industrial applications of PFAS. However, most of the PFAS-relevant content in both were  
93 written before the EPA’s Stewardship Program (2006)<sup>8</sup>, the addition of perfluorooctanesulfonic acid  
94 (PFOS; 2009), perfluorooctanoic acid (PFOA; 2019) and their precursors to the Stockholm Convention,<sup>11</sup>  
95 and a number of PFAS restrictions under the European Union REACH legislation<sup>27</sup>. The EPA’s Toxics  
96 Release Inventory (TRI), designed to inform the public of releases of toxic chemicals in their  
97 communities, can shed light on some larger sources of PFAS releases. However, it often falls short of the  
98 level of detail needed to characterize environmental contamination because it requires only self-reporting  
99 and contains extensive exemptions for many industry sectors (e.g., oil and gas), small businesses, facility  
100 cleaning and maintenance applications, and trade secret claims, among others. A recently proposed new  
101 rule under the Toxic Substances Control Act (TSCA) could overcome some of these key limitations for  
102 PFAS, as discussed in the “Paths Forward” section that follows.

103

104 As a further complication, emissions and exposures vary depending on the properties, production, use  
105 patterns and end-of-life treatments of the product and the PFAS applied. A recent broad overview of  
106 PFAS uses<sup>5</sup> in different consumer and industrial applications revealed a large number of little known uses  
107 such as in ammunition, climbing ropes, guitar strings, artificial turf, and soil remediation. For other areas  
108 (e.g., cosmetics, paints), PFAS use is known, but it is often less clear which specific PFAS have been  
109 employed and at what quantities. Such lack of knowledge about PFAS in industrial processes and  
110 products also impacts retailers and consumers. Public pressure to phase out hazardous chemicals has led

111 major retailers to remove certain PFAS from food packaging, clothing, and household furnishings<sup>28,29</sup>.  
112 However, retailers and product manufacturers often run into issues wherein PFAS are used somewhere  
113 along the supply chain but the exact use, PFAS type, and concentration are unknown. Proprietary  
114 information is used by industry as a justification for withholding the identity and concentration of  
115 chemicals in commercial products, with Confidential Business Information (CBI) claims used to protect  
116 details of formulas and manufacturing processes that confer an advantage over a company's competitors.  
117 This means that often little is publicly known about the identity and quantity of specific chemical  
118 structures present within a substance, formulation, or product.

119  
120 ***Potential Paths Forward:*** Chemical identities, production and consumption volumes, use locations and  
121 emissions, including of byproducts and impurities, need to be reported by industry, and such information  
122 needs to be made publicly accessible. Retailers and product manufacturers need to know and publish  
123 where PFAS are present in their supply chains to foster greater transparency and confidence in the  
124 composition and safety of end products. This will require public pressure, rules, and regulations. In June  
125 2021, the US EPA published a proposed update to the reporting requirements for PFAS under TSCA<sup>30</sup>  
126 that could facilitate this type of reporting. The new rule potentially applies to a larger number of PFAS  
127 and no longer exempts small-scale businesses that manufacture PFAS from reporting requirements, an  
128 acknowledgment of the particular concern raised by these chemicals. However, this rule is still limited to  
129 producers, and as such will not resolve the supply chain issues of identifying PFAS in and emissions from  
130 downstream products. In addition, confidentiality of production and import volumes and chemical  
131 identity are still supported under the proposed rule, thus continuing to limit public access to these critical  
132 data under CBI claims. Another potentially useful mechanism is greater use of product registries, such as  
133 are maintained by the Scandinavian countries<sup>31-33</sup>. These require manufacturers and importers to declare  
134 chemical substances and products (excluding food, cosmetics, and medicinal products) in excess of 100  
135 kg per year per company. Finally, a researcher-led approach to identifying PFAS occurrence in products  
136 and environmental emissions could entail greater use of coordination networks like NORMAN<sup>34</sup>. Such a

137 network can serve as a central touchpoint to harmonize analytical methods and share information on  
138 occurrence and effects of PFAS, but is limited to detecting pollution after it has occurred.

139

## 140 2. Where are the unknown PFAS hotspots in the environment?

141 **Importance:** The ability to identify geographic areas, environmental media, and populations with high

PFAS concentrations is crucial to manage exposures and for the development of  
models to predict PFAS transfer across environmental media, geographic borders, and  
food webs. The scientific community is well aware of certain contaminated sites such  
as airports and military facilities,<sup>35-37</sup> pulp and paper mills<sup>38</sup> and fluoropolymer

146 manufacturing facilities<sup>39-43</sup>, but others have only recently come to light<sup>44</sup>. Certain activities can lead to  
147 decade-long local releases that are poorly documented, because the respective PFAS amount is not  
148 substantial on a regional or global scale, and therefore difficult to identify without local knowledge.

149

150 **Barriers:** Region- or country-specific uses exist that may constitute important but primarily local  
151 contamination hot-spots. For example, high volumes of PFOS have been emitted in South America  
152 through the use of Sulfluramid, an insecticide containing the PFOS-precursor N-ethyl perfluorooctane  
153 sulfonamide used to control leaf-cutting ants<sup>45,46</sup> Moreover, small-scale manufacturers in both developed  
154 and developing countries have very different control practices in place, leading to PFAS emissions that  
155 are poorly understood in light of the current knowledge of a few large industries, mostly in the developed  
156 world. In developing countries, a general lack of access to the equipment, supplies, and infrastructure  
157 needed to perform PFAS analyses can hinder identification of hotspots, a particularly critical barrier  
158 discussed in detail under Question 3.

159

160 **Potential Paths Forward:** A systematic inventory of all PFAS industries is needed to identify current and  
161 former sites of emissions on a global scale. This requires international collaboration to integrate  
162 knowledge about locally important industries and practices. These inventories of industrial activities can

163 then be connected to known PFAS uses, enabling a systematic population of maps of potential PFAS  
164 contamination on a global scale, and bringing into focus areas that have been historically neglected in  
165 monitoring campaigns and/or research. This type of approach, for example using geographic information  
166 systems (GIS) to share and distribute data, is a means to organize knowledge and plan sampling  
167 campaigns on a global scale.

168  
169 At the same time, funding from multiple sources (industries, governments, foundations) for monitoring  
170 campaigns that screen diverse media (e.g. air, water, soils, sediments) for PFAS can identify geographical  
171 hot spots not connected to a known or suspected PFAS-associated activity. Data on emissions and  
172 environmental occurrence could be integrated and evaluated through the use of environmental fate and  
173 transport models<sup>47,48</sup>. Mismatches between model predictions and measurements can provide clues to  
174 missing emissions sources or hot spots. The data generated through these concerted efforts will be key to  
175 raising awareness at the governmental level on the urgency and scale of PFAS pollution, with the intent to  
176 motivate sufficient funding for monitoring and remediation activities on a large scale, as well as stopping  
177 ongoing emissions of identified local sources.

178

### 179 3. How can we make measuring PFAS globally accessible?

180 **Importance:** Overcoming uncertainties in global and local PFAS distribution and exposure, and closing

181 critical geographical and biological data gaps as discussed above also requires,  
182 fundamentally, the ability to actually detect and measure a wide range of PFAS  
183 compounds in myriad locations and in diverse environmental and biological  
184 media. Analytical methods are needed for environmental media, drinking water,

185 sewage sludge, foods, blood, fat, and various kinds of products and technical mixtures for monitoring and  
186 enforcement of current and upcoming regulations. Giving more researchers, communities, health-care  
187 providers, utilities, and businesses the ability to accurately detect PFAS will facilitate efforts to minimize  
188 exposure, protect vulnerable populations of humans and wildlife, and evaluate the effectiveness of

189 interventions. Making resources available to scientists in developing countries and developing rapid and  
190 cost-effective analytical approaches that are reliable and accessible will greatly improve the  
191 understanding of PFAS sources, fate and transport in areas where relatively little is currently known, such  
192 as Africa, Central America and parts of Asia.

193

194 **Barriers:** Until now the ability to measure and monitor PFAS has largely been restricted to well-  
195 resourced groups and countries with access to equipment, standards, infrastructure, and expertise. Well-  
196 established methods that can achieve high sensitivity with robust quality control require sophisticated  
197 analytical equipment (e.g. liquid chromatography tandem mass spectrometry, LC-MS/MS) that is  
198 expensive to acquire and requires specialized expertise to operate and maintain. In the past, the analysis of  
199 PFAS has been particularly challenging due to the presence of PFAS in certain laboratory and sampling  
200 materials and equipment, requiring control and monitoring of contamination, though measures have been  
201 developed to overcome this challenge<sup>49,50</sup>.

202

203 Reliable and well-documented protocols are still limited to a narrow range of PFAS, and high-quality  
204 analytical reference standards that enable targeted analysis with reliable quantification are expensive, and  
205 still unavailable for many PFAS. Commercial standard providers<sup>51,52</sup> cover only about 80 different PFAS,  
206 plus variations (i.e., branched isomers or mass-labeled compounds). Without the availability of analytical  
207 standards, non-targeted analysis methods with expensive equipment and expertise are needed to identify  
208 unknown PFAS<sup>53,54</sup>. Recent actions by a PFAS producer may set a worrisome precedent. According to a  
209 letter sent by Wellington Laboratories to its customers in January 2021, the PFAS manufacturer Solvay  
210 has threatened to sue Wellington for patent infringement for their sale of a standard for a novel PFOA-  
211 replacement in Solvay's fluoropolymer production (CAS 1190931-41-9)<sup>55</sup>. This raises the potential for  
212 industry to monopolize access, maintain secrecy, and delay progress in establishing occurrence and  
213 toxicity data for these substances.

214

215 **Potential Paths Forward:** While the low (part per trillion) limit levels instituted for PFAS in drinking  
216 water in many jurisdictions<sup>9,56</sup> require high sensitivity methods and rely on the availability of standards,  
217 for purposes such as screening of sites or products, simpler lower-cost methods may suffice. There are  
218 several Total Fluorine (TF) methods to detect the presence of fluorine or fluorinated compounds (e.g.  
219 CIC<sup>57</sup>, PIGE<sup>58</sup>, and XPS<sup>83</sup>), which can be combined with sample preparation methods such as extractable  
220 organic fluorine (EOF<sup>59</sup>) to provide rapid screening of both abiotic and biotic matrices. Much research is  
221 ongoing to develop additional methods, such as versatile and low-cost PFAS sensors<sup>60-62</sup>. Whatever their  
222 technical approach, methods should be validated across laboratories and ideally standardized. Positive  
223 steps in this direction were recently illustrated for EOF measurements in water compared to total targeted  
224 PFAS in a Swedish interlaboratory comparison study<sup>63</sup>.

225  
226 Capacity building efforts can support a pipeline for training and technology transfer from better resourced  
227 countries and institutions. Some programs already exist for instrument donation, such as the Seeding Labs  
228 program on Instrumental Access that donates equipment to promote research and education in developing  
229 countries<sup>64</sup>. Such programs are important, but represent only a small part of the solution to this enormous  
230 challenge. In addition to equipment, access to supplies (e.g. standards, solvents) and reliable infrastructure  
231 (electricity, water, gases) is crucial and often unavailable. To make these efforts accessible and  
232 sustainable, traineeships could be established for scientists in under-resourced regions to learn PFAS  
233 analysis at host laboratories. This would provide the opportunity for scientists in regions without  
234 adequate infrastructure to collect local samples to be analyzed at the host institution, while retaining  
235 ownership of the data and authorship in resulting publications.

236

237 **4. How can we safely manage PFAS-containing wastes?**

238 **Importance:** As PFAS are phased out of specific products and uses, safe disposal of existing stockpiles

239 becomes an urgent need. There are many diffuse sources of PFAS, such as textiles,  
240 food contact materials, personal care products, and household furnishings, that  
241 eventually enter landfills and wastewater, and are later re-emitted to the  
242 environment through the air, landfill leachate, or into soil from biosolids

243 application<sup>65-67</sup>. Within recycling streams, separation and safe disposal of PFAS contained within

244 complex matrices become extremely challenging, given knowledge gaps on which types of PFAS are

245 present, and at which levels, in various types of waste. Knowledge on how to deal with PFAS-containing

246 waste is also critical for legislation related to regulations such as EU REACH and the Stockholm and

247 Basel Conventions and ongoing PFAS restrictions.

248

249 **Barriers:** Multiple technologies are being developed to remove PFAS from contaminated soil and water,

250 some of which have proven effective, but high long-term cost and energy use remain major challenges.

251 For example, sorptive or membrane-based processes result in contaminated wastewater streams (spent

252 sorbent, membrane rejectate) that must be disposed of. Most desirable are in-situ clean-up methods (not

253 “pump and treat”) but, so far, such a remediation solution has not been found. Large-scale water treatment

254 facilities can be equipped with advanced treatment technologies (e.g. reverse osmosis) to remove

255 persistent and mobile (water-soluble) chemicals like PFAS, but these are prohibitively costly to install

256 and maintain for small systems<sup>68-72</sup> and also generate PFAS-containing waste.

257

258 High-temperature incineration has been proposed for some concentrated stocks (e.g. aqueous film-

259 forming foams), but given the high stability of the carbon-fluorine bond, there are concerns whether

260 incineration is consistently operated under conditions that ensure the full mineralization of PFAS. In

261 Europe, flue gases from municipal waste incinerators are meant to run at a temperature of 850 °C for at

262 least two seconds<sup>73</sup>, but studies show that complete combustion of PFAS such as PFOA and PFOS

263 requires temperatures of at least 1000 °C<sup>74</sup>. Limited work is underway to monitor incineration plants for

264 emissions of PFAS, but few data from full-scale studies are yet available<sup>75</sup>. While intensive research is  
265 ongoing to identify and optimize routes of PFAS biodegradation<sup>76-78</sup> as a potentially less energy- and  
266 cost-intensive solution, none are currently effective at complete mineralization under reasonable time-  
267 scales.

268

269 **Potential Paths Forward:** Given the difficulties and costs associated with the disposal of PFAS, an  
270 upstream solution (i.e. avoiding PFAS except for cases of essential uses) is the most effective means of  
271 dealing with future PFAS-waste. The production of PFAS for essential uses should also be carefully  
272 controlled to result in close-to-zero emissions, because the few options available for safe disposal will  
273 always be costly based on currently available and foreseeable technologies. Recovery of PFAS from such  
274 uses is another important measure to ensure the need for energy-intensive destruction is avoided. Product  
275 labeling can be effective in reducing use and emissions of hazardous chemicals including PFAS, but trace  
276 PFAS contamination within recycling streams may prevent recycled materials from being incorporated  
277 into goods labeled PFAS-free. Given existing background levels, it may be necessary for PFAS-free  
278 labeling to include an allowance for trace, non-functional levels of PFAS for industry partners trying to  
279 move away from fluorinated chemicals.

280

281 Even when an “ideal” future can be achieved where only essential uses of PFAS occur and PFAS from  
282 these uses are recovered and not released, there are still the problems of legacy PFAS contamination and  
283 ongoing PFAS emissions. To address existing and ongoing waste issues, funding and research should be  
284 targeted towards technologies that can destroy PFAS with reasonable cost and environmental  
285 performance. Hybrid technologies that combine sorption and mineralization (“concentrate and destroy”)  
286 approaches may be particularly helpful in dealing with initially complex and dilute waste streams.  
287 Whatever the approach, the re-emission and shifting of contamination across environmental media (e.g.  
288 from soil to air) must be prevented. This also argues against testing of destruction technologies at scale  
289 until proven strategies are in place to prevent re-emission. Until these technologies can be better

290 developed, confined disposal facilities that store PFAS wastes while preventing emissions via air and  
291 leachate may be a best imperfect choice.

292  
293

## 5. How can we understand and describe the health effects of PFAS exposure?

294 **Importance:** Toxicological assessment of each of the thousands of PFAS is not required to decide that

295 further environmental contamination by PFAS and subsequent exposure should be  
296 avoided. However, pressing questions remain about how to deal with historical and  
ongoing PFAS pollution and associated health effects. To address the potential  
effects of existing exposures, and to prevent the extensive use of similarly

299 bioavailable and toxic substances in the future, it is important to understand how to link measured  
300 exposures (e.g., levels of specific PFAS in blood) to current or anticipated health effects. It is also critical  
301 to link those health effects to specific physical-chemical properties and modes or mechanisms of  
302 toxicological action of PFAS, for example through adverse outcome pathways, AOPs. Concerns about  
303 their bioaccumulation and toxicity led to the global phase-out of a number of PFAAs. Yet advances in  
304 non-targeted analysis have facilitated discovery of many other structurally similar compounds in the  
305 environment, wildlife, and humans<sup>16,42,80,81</sup>. Some of the newly detected compounds are attracting  
306 increasing attention as they replace phased-out PFAAs in processes and products<sup>41,82,83</sup>, although  
307 they have in fact been released for decades in certain industries<sup>84-86</sup> but were under the radar of the  
308 scientific and regulatory communities. The tissue distributions and bioaccumulation potentials are still not  
309 well understood<sup>79,80</sup>, but laboratory studies suggest that several replacement PFAS bioaccumulate and/or  
310 exert toxic effects similar to the compounds they have replaced, as well as other distinct toxic effects<sup>44,81-</sup>  
311 <sup>84</sup>.

312

313 **Barriers:** One of the most difficult questions scientists working on PFAS face is that of causality: is a  
314 health condition suffered by a community member the result of their exposure to PFAS, or does a blood  
315 test indicating the presence of PFAS mean that they will become sick in the future? Communities with

316 contaminated water supplies face challenges in court to having their health and remediation costs covered  
317 by the parties thought responsible for the contamination. To make the link between exposure and effect,  
318 clear lines of evidence are needed to both document the exposure and explain how it leads to an observed  
319 adverse health impact<sup>87</sup>. A striking feature of PFAS toxicity is the diversity of biological pathways that  
320 are affected<sup>88</sup>, especially given that most of the toxicological data currently available for PFAS are for a  
321 few single PFAAs. Understudied groups of PFAS (e.g. neutral, cationic, zwitterionic, cyclic) may have  
322 substantially different biological behavior that could be missed by established sampling approaches. For  
323 example, if their tissue distributions vary from those of anionic PFAAs, focusing on only serum or liver  
324 concentrations could miss critical accumulation sites for these PFAS (e.g. in lipids<sup>89</sup>). The structural  
325 diversity of PFAS and the fact that exposures are nearly always to mixtures rather than single substances  
326 complicates the search for mechanisms and structure-activity relationships.

327

328 ***Potential Paths Forward:*** The use of class-based methods to evaluate PFAS can work as a  
329 precautionary approach in the face of continuing uncertainty, particularly with respect to curtailing new or  
330 continuing uses of PFAS<sup>90</sup>. For existing exposures, additional, appropriately funded epidemiological  
331 studies that target large populations with a diversity of primary exposure routes can help to develop better  
332 links between exposure and effect, especially for less-studied PFAS and exposure routes. Analyses in  
333 these studies should include not only blood but also other matrices (urine, breast milk, hair, lipid tissues)  
334 to capture a wider diversity of PFAS physicochemical properties, half-lives of elimination, and potential  
335 internal storage sites. When occurrence data in populations are combined with PFAS identities and  
336 concentrations in products and environmental matrices, as discussed under questions 1 and 2, scientists  
337 can begin to develop “signatures” for exposures to PFAS from specific sources. Such information would  
338 be highly useful in the design of effective interventions to minimize exposures. Strategic and periodically  
339 implemented human biomonitoring studies combined with environmental exposure assessments can also  
340 evaluate effectiveness of regulatory initiatives<sup>91,92</sup>.

341

342 Better integration of mechanistic and observational studies can reveal how PFAS induce adverse health  
343 outcomes in humans and wildlife. Computational and in-vitro approaches (e.g. toxicokinetic models<sup>93,94</sup>,  
344 food-web bioaccumulation models<sup>95-97</sup>, protein and phospholipid interaction models and in-vitro  
345 studies<sup>98-103</sup>) can provide insight into expected exposures and effects in diverse species. However, these  
346 newer approaches still face substantial barriers to inform policy, as regulatory approaches still often  
347 require that risk assessment used to support regulatory standards be based on human epidemiology data or  
348 in vivo animal toxicology data. These data are largely lacking for many of the PFAS now widely detected  
349 in the environment. Strategies to incorporate in vitro and computational data into regulatory framework  
350 would allow for more rapid expansion of risk assessment to emerging PFAS. Such studies could be  
351 further strengthened by systematic reviews of existing data to confirm or refute linkages between  
352 exposures and outcomes. To avoid regrettable substitution with existing PFAS and non-PFAS  
353 alternatives, information revealed about modes or mechanism of toxic could also be used to inform future  
354 chemical design. Chemists should incorporate principles of hazard assessment, including structure-  
355 activity relationships, early in the molecular design phase to aid in the development of chemicals that are  
356 less persistent, bioavailable and toxic.

357

## 358 **6. Who pays for the impacts of PFAS contamination?**

359 **Importance:** A 2019 study for the Nordic Council of Ministers estimated the costs for Europe of water

360 treatment and soil remediation due to contamination of a sub-set of PFAS at between  
361 EUR 10-20 billion over a 20-year period<sup>104</sup>. Testing of publicly supplied drinking  
362 water sources indicates that as many as 80 million US residents may be receiving  
363 water with PFAS levels exceeding limits recommended by regulatory agencies and  
364 toxicologists.<sup>9,105-107</sup> These communities may face costs ranging from purchase of replacement (bottled)  
365 water to major capital expenditures and long-term maintenance of water treatment technologies by their  
366 water utilities, which are transferred to consumers through their water bills<sup>108-111</sup>. Removal and disposal  
367 of contaminated soil or treatment of groundwater (e.g., pump and treat) is particularly expensive<sup>112</sup>, and is

368 therefore rarely undertaken. Indirect costs can include loss of property value or closure of a business if  
369 contamination is found. Examples include an organic farm in Colorado that had to stop growing crops  
370 because its water supply had been contaminated by PFAS from fire-fighting foam<sup>113</sup>, and a dairy farm in  
371 Maine that had to cull its herd because the milk had levels of PFAS 60 to 150 times higher than health  
372 advisory levels, due to applications of contaminated paper mill sludge to pastures as fertilizer<sup>114</sup>.

373  
374 Moreover, projected health-related costs due to effects of PFAS exposure are many times higher than the  
375 costs of environmental remediation. The Nordic study estimated the costs of human-health impacts from  
376 exposure to PFAS to be a minimum of EUR 54-82 billion *each year* in Europe. Direct costs will include  
377 medical treatment for PFAS-related health impacts such as cancer, high blood pressure, obesity and low  
378 birth weight. Indirect costs range from lost years of life and/or lost quality of life, impacts on family or on  
379 mental health because of anxiety about PFAS exposure, and ongoing health monitoring.

380  
381 **Barriers:** Costs of environmental and health impacts from PFAS exposure, like most environmental  
382 damages, continue to be treated as negative externalities – costs not borne by the polluter carrying out the  
383 activity causing the exposure, but by society at large. The major barrier to covering these enormous costs  
384 is lack of political agreement concerning who is responsible for this contamination and exposure, and who  
385 should pay. While the “Polluter Pays Principle” was first defined and championed by the OECD in 1972,  
386 it has rarely been implemented<sup>115</sup>. When local, regional, or national governments step in to finance clean-  
387 up of drinking water and other remediation processes, the costs are ultimately passed on to the taxpayer.

388  
389 The costs of health impacts from PFAS exposure are often borne directly by the individuals who have  
390 developed the disease and by healthcare systems, because of complexities associated with establishing  
391 direct causal links between pollution and the health impact. The relationship between exposure and  
392 disease can be particularly difficult to verify when impacts of exposure do not arise until many years later  
393 (e.g., cancer). In the US, a few legal actions for compensation have been successful, e.g., a class action

394 suit against Dupont/Chemours on behalf of 70,000 persons exposed to industrial discharges in West  
395 Virginia settled for \$670 million and a State of Minnesota lawsuit against 3M for water contamination  
396 settled for \$800 million. However, the PFAS released by these companies remain in the environment and  
397 will likely remain a source of exposure for generations, not covered by these lawsuits.

398

399 **Potential Paths Forward:** The extreme persistence of nearly all PFAS highlights the absurdity of  
400 continuing to treat environmental damage—including damage to public health—as a negative externality  
401 that can be ignored or even denied by the emitter. Such long-lived environmental contamination does not  
402 simply shift a burden but rather extends it, indefinitely, to future generations and all species. This is not a  
403 transaction that can be supported in a sustainable society for the sake of preserving a specific market or  
404 manufacturer. Mechanisms already exist that could be activated to shift cost burdens away from  
405 communities and taxpayers, such as the aforementioned Polluter Pays Principle. The Superfund program  
406 under the Comprehensive Environmental Response, Compensation, and Liability Act of 1980 (CERCLA)  
407 in the United States<sup>116</sup> can hold polluters retroactively liable, but requires that the chemical to be  
408 remediated is first designated as a hazardous substance. The designation of PFAS as hazardous substances  
409 in the US is still under debate<sup>117</sup>, but would mark an important step forward in assigning liability.

410

411 However, liability might justifiably lie with different parties under different circumstances. Should the  
412 polluter be defined as the company that released the PFAS-containing material into the environment or  
413 the company that manufactured the material in the first place? Was the product that contained PFAS  
414 properly used? Was it properly disposed of? Was the user sufficiently informed about the risks of release?  
415 How should that liability be treated when companies merge, split, and otherwise change their structure  
416 and identities, such as when Dupont spun off Chemours in 2015 and offloaded much of their PFAS-  
417 related liability<sup>118</sup>? A number of cost recovery mechanisms have been suggested under the Strategic  
418 Approach to International Chemicals Management<sup>119</sup> that could help countries to address these issues, by  
419 funding assessment, remediation, and health care costs. These include collecting fees from companies

420 who wish to register chemicals for use, charging environmental protection taxes, and charging for  
421 permits.

422

### 423 **Conclusions: Answering Urgent Questions to Address the PFAS Problem**

424 While these urgent questions highlight critical gaps in current understanding of the PFAS problem,  
425 enough is already known to take action. Costs associated with environmental cleanup and ongoing health  
426 effects of chemicals are magnified for extremely persistent environmental contaminants<sup>4,120</sup>, adding  
427 urgency to efforts to phase out current non-essential uses of PFAS<sup>121</sup>. Beyond these well-founded  
428 precautionary actions, the most important step is to improve the transparency about where and in what  
429 quantity PFAS are used. This will aid in identifying and phasing out all non-essential uses of PFAS and  
430 provide opportunities to identify less hazardous substitutes for PFAS. Production of safer chemicals and  
431 products must be seen as a competitive advantage and as a driver for innovation and the opening of new  
432 markets.

433

434 Consumers are increasingly demanding that the products they use minimize their own health risks as well  
435 as risks to environmental health. These consumer-driven initiatives place pressure on major retailers to  
436 remove known problematic chemicals—e.g., bisphenol A (BPA)<sup>122</sup>, polybrominated diphenyl ethers  
437 (PBDEs)<sup>123</sup>, and, now, PFAS—from their products, and have proven enormously effective. However, this  
438 is not a perfect system, as illustrated by the case of BPA, where consumer pressure led to its replacement  
439 by bisphenol S (BPS), which has turned out to be just as harmful as BPA<sup>124</sup>. Thus, while consumers can  
440 demand that known harmful chemicals be removed from their products, it is up to industry under the  
441 purview of scientific and regulatory communities to ensure that regrettable substitutions do not occur. A  
442 first step would be to move towards household goods, cosmetics, food-packaging materials, and personal  
443 care products with a smaller total number of ingredients, simplifying the assessment of a particular  
444 formulation.

445

446 While consumers have direct purchasing power, their ability to use this to avoid hazardous substances is  
447 impeded by the lack of transparency in product ingredients and increasing cases of ‘greenwashing’. Major  
448 retailers and institutions in charge of public procurement, on the other hand, can wield much more  
449 concentrated power as well as knowledge about product supply chains. When large multinational  
450 corporations demand that their product lines remove certain hazardous chemicals, it helps in the voluntary  
451 restriction of those chemicals and also serves as a driver for innovation in the search for less hazardous  
452 alternatives. One particularly effective means for public agencies and retailers is through the use of lists  
453 of prohibited chemicals, such as the “Substitute it Now” (SIN) list,<sup>31</sup> which can serve as a scientifically-  
454 vetted ‘manual’ of chemicals to avoid. Compilation and curation of such lists, as well as their  
455 counterparts—lists of preferred less hazardous chemicals and products such as US EPA’s Safer  
456 Choice<sup>125</sup>—can help to prevent the chemical whack-a-mole game of regrettable substitutions.

457  
458 The environmental health impacts of a chemical used in a product are often not borne by the same  
459 population who benefits from the sale and use of these products. Production of PFAS has shifted to  
460 China, India, Brazil, and other countries where there is little awareness of the public health risks from  
461 PFAS and almost no environmental or human health monitoring. Extremely high exposures are already  
462 occurring, as was recently documented near a production facility in China<sup>44</sup>. A key component of the  
463 solutions we propose here is to ensure that PFAS research and monitoring is supported in more countries,  
464 with the goal to alleviate the impacts of “off-shoring” the negative repercussions of emissions associated  
465 with the production and end-of-life of PFAS and PFAS-containing products. In answering urgent  
466 questions for the sustainable management of PFAS, technological and policy interventions cannot be  
467 effective without also addressing environmental equity.
