KEYWORDS

conservation, policy/ethics, wildlife science, animal welfare

ABSTRACT

The ethical position underpinning decisionmaking is an important concern for conservation biologists when setting priorities for interventions. The recent debate on how best to protect nature has centered on contrasting intrinsic and aesthetic values against utilitarian and economic values, driven by an inevitable global rise in conservation conflicts. These discussions have primarily been targeted at species and ecosystems for success, without explicitly expressing concern for the intrinsic value and welfare of individual animals. In part, this is because animal welfare has historically been thought of as an impediment to conservation. However, practical implementations of conservation that provide good welfare outcomes for individuals are no longer conceptually challenging; they have become reality. This reality, included under the auspices of “compassionate conservation,” reflects an evolved ethic for sharing space with nature and is a major step forward for conservation.

Every day, environmental policymakers, conservation practitioners, and land managers, make decisions that affect the lives of wild animals. The societal norms that shape the context for those decisions are complex, entrenched, and often opaque to the wider community. Despite the complexity, there is growing awareness that conservation decisions— particularly those aimed at resolving conflicts between humans and other animals but also conflicts between other animals—often result in the harm and death of other animals. That these animals carry the burden of achieving conservation objectives through their harm and death is often ignored or else justified on utilitarian grounds. It is common for some members of a single species to be killed for the “good” of their species or for members of one species to be killed for the “good” of another species (e.g., golden hamsters for black-footed ferrets; Bekoff 2010). Animals are also routinely killed to prevent them from moving from protected areas to private land (e.g., wolves and dingoes; Treves and Karanth 2003) and because they are considered to be invasive or pests (Littin 2010). These trade-offs often result in harm and death for captive and wild animals, justified in the name of conservation and human benefit (Callicott 1990, Bekoff 2003, Ben- Ami et al. 2014). The question is

where the trade-offs stop and the protection of individuals begins. How many individuals are acceptable to kill and harm in the name of conservation (Vucetich and Nelson 2007) and at what point does their well-being matter (Bekoff 2013)? Conservation practice and policy have historically addressed this question uncertainly and often without virtue (Vucetich and Nelson 2013). This has not been an easy question to resolve, primarily because the problem has not been with conservation itself, but rather with the manner in which it has been performed.

In turn, this situation can, in part, be attributed to the perceived difficulty in comparing complex and competing sets of values (e.g., individual rights and values versus ecosystem health), notions of human exceptionalism and dominance, and the overly strong focus on species welfare (as opposed to individual welfare) in conservation metrics. The result is that without consensus on how to accommodate what appear to be contradictory values, moral confusion and ethical dilemmas are common. Consequently, there has traditionally been a lack of animal welfare concern in conservation decisionmaking when addressing the stark but real question of which animal lives and which animal dies, in part because of past disagreements between conservation and animal welfare scientists on the role of individual welfare in conservation (e.g., Soulé 1985). Environmental legislation and policy is almost wholly grounded in measures of species and ecosystem welfare (Gaston and Fuller 2007), with little emphasis on individual welfare. In contrast, animal welfare legislation often has tight control over the individual welfare of domestic animals and livestock. Wild animals are frequently exempted from animal welfare legislation by categorizing them as *pests*, a term used to define a species that is a nuisance, out of balance, invasive, or exotic (Nagy and Johnson 2013). Often, the issues faced by conservation managers are in relation to species that are placed in this category, and, perhaps not coincidentally, transgressions of humane treatment are frequently justified by the application of this label (Littin 2010).

Language and culture are strongly linked to our treatment of other animals (Webb and Raffaelli 2008). Societal norms are often rendered with euphemisms to surmount the impression of transgressions of equity and justice, therefore obscuring the obvious ethical conflict our actions cause. Bias in the selection of flagship species to protect, such that flagship species are used to leverage support for broader conservation objectives, is a complex mix of charisma (Lorimer 2007, Tisdell and Nantha 2007) and politics (Yeo and Neo 2010). Animal protection is strongly influenced by prevailing views on sentience and cognition (Bekoff and Jamieson 1990), position on the phylogenetic scale (Harrop 1999), and utility to humans (O'Sullivan 2011). Of course, not all species can be saved from extinction, nor can all individuals be spared from dying or suffering needlessly at the hands of humans. But there is currently little deliberate ethical enquiry in how trade-offs in lives are made (Larson 2007), and there has been little room for empathy (Bekoff 2013).

Blockages in conservation decisionmaking

The focus on species welfare and anthropocentric views of nature has been an impediment to scientifically validating the inclusion of individual welfare in conservation. Although species welfare, with its focus on the prevention of extinction, is a vital and admirable conservation objective, the welfare of individuals and their social groups should also be considered as important. Harm to animals is more than just the extinction of species and subsequent declines in biodiversity. This awareness stems from the dramatic rise in human-wildlife conflicts (Redpath et al. 2013) and a growing recognition of the intrinsic value of conscious and sentient animals (Bekoff 2007, 2014). Harm also encompasses the suffering experienced by individuals and associated costs to social units and the populations to which they contribute (Fraser 1993, Paquet and Darimont 2010). Although many of these harms result from global conservation problems, such as habitat loss, climate change, and pollution, many harms paradoxically result from humans engaging in proactive conservation measures (Fraser and MacRae 2011).

Although clear and inclusive ethical foundations for conservation have been articulated numerous times, these foundations have been gradually eroded by human needs and benefits and prevailing views of human exceptionalism. Motivations for humans to engage in conservation encompass a wide variety of societal values, incorporating ethical, aesthetic, and economic concerns (Doak et al. 2013). These often-competing values are increasingly resulting in conflict and present considerable philosophical, moral, and practical problems for conservation planners and policymakers. Conservation interventions require decisionmakers to make trade-offs among philosophical and ethical value sets and practical limitations. Problematically, conflict resolution between conservation and other human endeavors is, more often than not, dictated by decisionmaking aimed at economic and utilitarian values (Artelle et al. 2014), to the detriment of aesthetic and ethical values (Jepson and Canney 2003). The denial of the intrinsic value and sentience of nonhuman animals is also strongly influential. Despite having the protection of animals and conflict resolution at its heart, conservation science as a discipline has struggled to establish a strong environmental ethic and moral philosophy, to the detriment of individual animals.

Conservation is ethically challenged

Discourse surrounding the ethical position of conservation is not new (Ehrlich 2002, 2009, Minter and Collins 2005, Dunlop 2006). Although the dominant paradigm governing conservation policy is based on a limited anthropocentric version of utilitarianism, which is a form of consequentialism, there are several other ethical positions with implications for conservation and animal protection, such as deontology (Regan 1983) and deep ecology (Naess 1973, Routley 1973) that reject the utilitarian view of the environment (i.e., the shallow view). The importance of ethics in conservation was noted as part of the founding principles of the Wildlife Society in 1937 in the United States, in which the “development of all types of wildlife management along sound biological lines” was seen as a crucial move away from indiscriminate exploitation for human benefits (Bennett et al. 1937). Aldo Leopold further championed this idea in 1949 with his land ethic (Leopold 1949). At that time, Leopold firmly embedded the sharing of land between humans and other animals in his land ethic, allowing for both the preservation of wilderness where possible and for economic exploitation (Callicott 1990). Importantly, the land ethic approach encompassed the view that individuals and their well-being mattered (Davradou and Namkoong 2001). The implementation of this ethic, however, has remained stymied by the more dominant anthropocentric utilitarian ethic that espouses decisions that promote overall well-being (actions for the greater good). Not only has exclusive concern for human benefits taken a strong hold of motivational mechanisms (e.g., as proposed in the new conservation; Kareiva and Marvier 2012), but the grounding of conservation in species welfare has, perhaps unintentionally, subjugated individuals for collective benefits.

The challenge for conservation science is to decide whether current decisionmaking in practice and policy evolves to accommodate contemporary moral systems and to incorporate the rapidly developing scientific understanding of the sentience and consciousness of nonhuman animals or whether, at a practical level, the trumping of welfare outcomes for individual animals by species (or population or ecosystem) welfare or by human benefits continues to be permissible (Fraser 2012). Evidence from conservation policy suggests that this challenge is often sidestepped and that the *status quo* remains by default (Artelle et al. 2014). Why has this happened? Negativity toward individual welfare has become entrenched because it has been viewed as an impediment to holistic decisionmaking. Dominant and entrenched values are maintained through individual and collective aspirations (Jepson and Canney 2003) and through cultural norms and perceptions (Lejano and Fernandez de Castro 2013), whereas disengagement of moral self-sanctions allow for harmful practices by removing self-restraint (Bandura 2007). Entrenched views can have a significant and wide-ranging influence on conservation policy and decisionmaking, such that vocal stakeholders often assert value-based rhetoric to the detriment of alternative value sets (e.g., Ramp 2013). This is evident in a wide variety of conservation issues that result in direct conflict between

advocates of alternative positions (Redpath et al. 2013) but, conversely, can also drive efforts to alleviate conflicts via education programs and comanagement strategies (e.g., Gelcich et al. 2008).

Compassion in conservation

The good news is that the asserted dichotomy between conservation and animal welfare has waned, and the unifying aim of reducing harm to nonhuman animals in both these disciplines has gathered momentum (Fox and Bekoff 2011, Fraser 2010, Littin 2010, Paquet and Darimont 2010, Bekoff 2013, 2014). The challenge has been for decisionmakers to establish a practical framework (i.e., one that is ideologically sound and able to be implemented through on-ground activities) that accommodates the ethical and moral position of individual animals within conservation practice (Bekoff 2002). In a case of widespread convergent evolution, examples of conservation initiatives aimed at achieving both conservation goals and reduced harm to individuals have emerged over the last few decades. Despite the dominant lethal paradigm underlying many conservation initiatives (Bergstrom et al. 2014), compassionate approaches to solving conflicts between humans and wildlife have evolved. These highlight the rise of what has been termed *compassionate conservation* (Bekoff 2010, 2013), a rapidly growing international and cross-disciplinary movement that stipulates that we need a conservation ethic that incorporates the protection of other animals as individuals, not just as members of populations of species but valued in their own right.

The evolutionary underpinnings for the ethical behavior of compassion lie in the evolutionary processes that reward empathic adaptations (Goetz et al. 2010), but compassion can be practically defined as reflecting empathy in humans for nonhuman animals and a drive to alleviate harm and suffering. Unlike the dominant utilitarian approach to conservation, which puts the cost of reaching conservation targets squarely on the shoulders of other animals, a compassionate ethic for conservation brings empathy into decisionmaking alongside other values. It is not a rights position but, rather, puts forward a scientific and evidence-based conceptual approach that stipulates that conservation initiatives should first do no harm (Bekoff 2010). This is important not only because of what we now know about the cognitive and emotional lives (consciousness and sentience) of other animals (Bekoff 2007, Bekoff and Pierce 2009) but also as a moral imperative for providing modern solutions for sharing space with nature and for fostering the possibility for diverse species to live in peaceful coexistence (Hinchliffe et al. 2005). Compassionate conservation allows for—but does not prescriptively dictate—outcomes in which the interests of others supersede those of humans.

Examples in which compassionate conservation principles are being applied have been steadily growing. Predation by carnivores is being successfully managed using fencing, fladry, and guard animals (Fox and Bekoff 2011) rather than through shooting, trapping, and poisoning programs. Pack structures in unexploited predator populations show evidence of declining rogue behavior and pack stability (Purcell 2010), thereby reducing negative interactions with humans (Bekoff and Jamieson 1996). Issues in which species interfere with human endeavors are being solved by focusing on holistic ecological solutions and educational programs (e.g., restricting access to rubbish tips and putting roofs on city rubbish bins for ibis in Australia, as in Martin et al. 2012, and the use of fencing and local community engagement in the management of brown bears in Turkey; Ambarli and Bilgin 2008). The costs of ignoring individual welfare in scientific programs are also gaining attention (Jewell 2013), because mainstream invasive techniques for studying animals are now known to be stressful and change species-typical behavior (Bekoff 2000). Human–wildlife conflicts can be exacerbated by a lack of science, transparency, and concern for harm to animals in decisionmaking (Artelle et al. 2014).

Compassionate conservation is challenging decisionmakers to have clear objectives where the lives of animals are affected. If interventions are necessary, the range of values of different stakeholders (human,

nonhuman) should be articulated so that trade-offs may be transparently evaluated. Adaptive management principles are a must, in which scientifically credible monitoring programs measure key performance indicators. For situations in which harm to animals, either from an individual or species welfare perspective, is part of an intervention option, clear data are needed on the minimum number of animals that will be affected to achieve the desired outcome. Rating systems for harm exist for domestic animals and livestock and should be integrated into conservation interventions targeting wildlife.

Cause for optimism and a call to action

Although millions of animals are killed in the name of conservation around the world each year, there is good cause to be optimistic. Acceptance of the intrinsic value of wild animals in nature and an associated motivation to prevent harm to those animals, is often reported as an almost universal ethic among a wide variety of stakeholders (Butler and Acott 2007, Dubois and Fraser 2013). Compassionate conservation can help by providing solutions to conservation conflicts that have either proved intractable to resolve or incurred a heavy welfare cost to wild or captive individuals. That is not to say that individual welfare supersedes species or ecosystem welfare, only that we cannot continue to ignore individuals in conservation practice. By considering animal welfare alongside animal conservation, it becomes possible to establish wildlife conservation frameworks that are explicitly oriented toward the management of the lives of individuals and their social groups and not just the species or population as a whole (Fraser 2010, Paquet and Darimont 2010). The word management reflects the fact that, in today's world, humans must interfere in the lives of other animals to resolve conflicts that inevitably arise from sharing space.

Despite clear progress, decisionmakers have only just begun to recognize the importance and utility of a compassionate and practical framework for conservation decisionmaking and triage. Difficult questions need to be asked about how best to engage with nature to resolve conservation conflicts. The aspirations underlying compassionate conservation have been long held by those interested in protecting nature, but as a movement, with a clear framework of operation, compassionate conservation is in its infancy. Factoring compassion into conservation presents a simple and morally acceptable approach to resolving issues of land sharing by using the universal ethic of a concern for the suffering of others and attempts to alleviate it. Peaceful coexistence with other animals and their homes, grounded in compassion, is needed in an increasingly human-dominated world if society is to preserve and conserve nature in holistic and humane ways.

Acknowledgments

We are indebted to the Born Free Foundation, particularly Will Travers and Chris Draper, for supporting and promoting the conceptualization of compassionate conservation. Liv Baker, Dror Ben-Ami, Louise Boronyak, and Kate Litten provided helpful discussion. The manuscript was greatly improved by comments from Paul Paquet and anonymous reviewers.
