Running Title: Maternal Immunization for Respiratory Syncytial Virus

24 **Abstract**

25
26 Maternal anti-respiratory syncytial virus (RSV) antibodies acquired by the fetus through
27 the placenta protect neonates from RSV disease through the first weeks of life. In the cotton rat
28 model of RSV infections, we previously reported that immunization of dams during pregnancy
29 with virus-like particles assembled with mutation stabilized pre-fusion F protein as well as the
30 wild type G protein resulted in robust protection of their offspring from RSV challenge (Blanco,
31 et al Journal of Virology 93: e00914-19, <https://doi.org/10.1128/JVI.00914-19>). Here we describe
32 the durability of those protective responses in dams, the durability of protection in offspring, and
33 the transfer of that protection to offspring of two consecutive pregnancies without a second
34 boost immunization. We report that four weeks after birth, offspring of the first pregnancy were
35 significantly protected from RSV replication in both lungs and nasal tissues after RSV challenge,
36 but protection was reduced in pups at 6 weeks after birth. However, the overall protection of
37 offspring of the second pregnancy was considerably reduced, even at four weeks of age. This
38 drop in protection occurred even though the levels of total anti-pre-F IgG and neutralizing
39 antibody titers in dams remained at similar, high levels before and after the second pregnancy.
40 The results are consistent with an evolution of antibody properties in dams to populations less
41 efficiently transferred to offspring or the less efficient transfer of antibodies in elderly dams.

42 **Author Summary:**

43 Respiratory syncytial virus (RSV) is a major cause of acute lower respiratory tract infection of
44 infants. Because there is no licensed vaccine for RSV as well as potential safety issues with any
45 new vaccine, protection of infants from RSV is problematic. A possible safe approach for infant
46 protection is the transfer of maternal anti-RSV antibodies, induced by immunization, across the

47 placenta to the fetus serving to protect the newborn for months after birth. In a cotton rat model,
48 we have previously shown that maternal immunization with virus-like particles assembled with
49 the RSV F and G proteins protects offspring from RSV infection. Here we describe protection of
50 offspring, following a single immunization, through two pregnancies showing that offspring of
51 the first were well protected from RSV challenge. However, offspring of the second pregnancy
52 were very weakly protected although the levels of total anti-pre-F antibodies and neutralizing
53 antibody titers in the dams remained at constant and high levels before and after the second
54 pregnancy. This result is consistent with an evolution of antibody properties in the dams to those
55 less efficiently transferred to offspring and highlights the importance of appropriate strategies
56 for maternal immunization, such as immunization during each pregnancy.

57

58

59 **Introduction**

60 Respiratory syncytial virus (RSV) is a very common cause of severe acute lower
61 respiratory tract infections in infants and young children, infections that frequently result in
62 hospitalization and, in developing countries, significant mortality (1-3). RSV accounts for
63 approximately three million infections per year world-wide with nearly 200,000 deaths. In the US,
64 RSV infections are the most common cause of infant doctor visits as well as a significant number
65 of hospitalizations (3). However, despite decades of effort, no vaccine has yet been licensed.

66 Attempts to develop RSV vaccines have been ongoing since the 1960s. Vaccine development
67 has focused on the RSV F protein which is more conserved across all strains of RSV than the G
68 protein and thus should induce protective responses across all strains. The early failures to
69 identify an effective vaccine were due, in part, to a lack of recognition that the pre-fusion
70 conformation of the RSV F protein induces optimal protective responses and that this form of F
71 protein is unstable (4, 5). Another issue is a significant concern about vaccine safety of all
72 candidates stemming from the failure of formaldehyde treated virus (FI-RSV), an early vaccine
73 candidate. FI-RSV was not only ineffective in preventing disease but, more importantly, resulted
74 in life-threatening enhanced respiratory disease (ERD) upon subsequent exposure to infectious
75 RSV (6-9).

76 Given these considerations, as well as the immunological immaturity of infants and potential
77 interference of maternal antibodies in infant vaccination (10, 11), a current view is that maternal
78 immunization with vaccines containing the mutation stabilized pre-fusion F protein is a safe and
79 efficacious approach for protection of infants against RSV (12-18). Maternal vaccines are
80 commonly used to protect infants from influenza, tetanus, and pertussis (19-22). It has been
81 reported that RSV maternal antibody (matAb) acquired by the fetus through the placenta or
82 lactation has a protective effect on neonates during the first few weeks of life (13, 17, 23-25).
83 Thus, a goal of the maternal RSV immunization strategy is to increase protective maternal
84 antibodies (matAbs) in neonates to levels that will extend the time of their protection after birth.

85 We have developed novel virus-like particle (VLP) vaccine candidates for RSV. VLPs robustly
86 stimulate immune responses without the complications of adjuvant addition due to their display of
87 repetitive arrays of antigen in a virus-sized particle (26, 27). Because production of VLPs does
88 not require viral replication, multiple antigens and different conformational forms of antigens can
89 be assembled into VLPs, in contrast to attenuated viruses which must remain infectious. VLPs
90 are safer as vaccines for many populations, such as the very young or the very old, compared to
91 infectious, attenuated, or vector viruses since they do not contain a genome and do not produce
92 a spreading infection.

93 McLellan et al identified mutations in the RSV F protein (DS-Cav1 mutant) that stabilize the
94 pre-fusion conformation, and this prototype pre-fusion F protein is now widely used in many
95 vaccine candidates in different stages of development (5). Subsequently, others have reported
96 different F protein mutations that are stabilizing (28), one of which, UC-3 F, induces higher
97 neutralizing antibody (NAb) titers than the widely-used form, DS-Cav1 F (28, 29). We have
98 assembled VLPs containing the DS-Cav1 or the UC-3 F pre-fusion RSV F proteins along with the
99 RSV G attachment protein and have established UC-3 F VLP superiority over DS Cav1 F as well
100 as post-F protein, or wildtype F protein containing VLPs in inducing NAb in both mice and cotton
101 rats (28, 30). Furthermore, we have tested the efficacy of these pre-F containing VLPs in the
102 cotton rat model of maternal immunization comparing responses to a post fusion F VLPs as well
103 as soluble versions of the pre- and post-fusion F proteins (18). In these studies, we have used
104 RSV-primed animals in order to mimic normal human populations, most of which have been
105 previously infected with RSV. We have reported that immunization of RSV-primed dams during
106 pregnancy with pre-F VLPs resulted in robust protection of offspring from RSV challenge with no
107 evidence of pathology (29-31). Here we describe the durability of these protective responses in
108 dams after a single immunization and compare the degree of protection these dams can transfer
109 to their offspring in two consecutive litters. We also assess the durability of protection in offspring
110 from each of these two consecutive breedings at extended times after birth.

111 **Results**

112

113 **Infection and Immunization**

114 To evaluate the durability of maternal antibody with time after VLP immunization and the
115 transfer of protection to offspring, three-week-old female cotton rats were first infected intranasally
116 (IN) with RSV (RSV-primed, day 0) in order to mimic the RSV-immune condition of the majority
117 of the adult human population. These animals were then set in breeding pairs at 56 days (breed
118 1) and immunized at two weeks of gestation (day 70) with one of two different pre-fusion F
119 containing VLPs, DS-Cav1 F or UC-3 F (Figure 1). Groups of animals were immunized with 25,
120 75, 100, or 150 micrograms of UC-3 F VLPs, or 100 micrograms of DS-Cav-1 F VLPs. Control
121 groups were immunized with 100 micrograms of stabilized post fusion F VLPs or re-infected (IN)
122 with RSV (RSV/RSV). Another group of RSV-primed animals did not receive immunization
123 (RSV/mock). Litters of pups delivered after the first breeding on or about (day 84) were divided
124 into two groups, one of which was RSV challenged at 4 weeks after birth while the other was RSV
125 challenged at 6 weeks after birth (Figure 1). RSV-challenged pups were sacrificed four days after
126 the challenge for assessment of serum antibody titers as well as virus titers in lungs and nasal
127 tissue.

128 The same dam cohort was bred again (breed 2) at 158 days after the RSV prime but
129 without a second immunization (Figure 1). Litters of pups delivered after this second breeding
130 (on or about day 185), were again divided into two groups, one of which was RSV challenged at
131 4 weeks after birth while the second at 8 weeks. Four days after challenge, virus titers in lungs
132 and nasal tissue were determined. Dams were maintained for a total of 318 days after RSV
133 priming to assess serum antibody levels late in their life. Serum samples from the dams and their
134 offspring were acquired throughout the protocol at intervals indicated by red arrows in Figure 1
135 for assessment of immune responses with time after immunization.

136 **Durability of anti-pre-F IgG in dams**

137 Sera from each group of dams from each time point were pooled for determination of the
138 total anti-pre-F IgG by ELISA. The levels of total anti-pre-F IgG antibodies increased significantly
139 after a pre-F VLP or Post F VLP single immunization at day 70, as we have previously reported
140 (18, 28, 31) (Figure 2, panels A and B) and remained relatively stable from day 141 to day 277
141 varying no more than 20%, with the exception of a drop at day 184 to between 43-58% of that on
142 day 141 (Figure 2, Table 1). Day 184 was just before the delivery of the second breeding. This
143 drop may be due to the transfer of matAb to the fetus just before delivery, a phenomenon we have
144 previously observed in primed, unvaccinated females during the first breeding but not in animals
145 vaccinated during their pregnancy (18). In animals immunized during pregnancy, the serum levels
146 at day 84 are a combination of increasing antibodies due to vaccination and decreasing levels
147 due to their transfer to the fetus. This point is supported by the observation that mock immunized
148 animals were the only group with a decrease in total Pre-F IgG on day 84 (Figure 2, A and B).
149 However, the levels of total pre-F IgG in the dams recovered by day 231 to levels similar to that
150 seen in day 141 (Table 1), suggesting their replenishment after pup delivery by anti-pre-F
151 secreting, bone marrow-associated long-lived plasma cells (LLPC). Indeed, there were
152 increased anti-pre-F IgG secreting LLPC in immunized animals compared to mock immunized
153 animals upon sacrifice of the dams on day 318 (Figure 3).

154 Measured levels of total anti-pre-F IgG in all serum samples were consistently slightly
155 higher when soluble UC-3 F instead of soluble DS-Cav1 was used as target for ELISA (Figure 2,
156 panels A and B) suggesting either that the UC-3 F target detects a broader range of antibody
157 specificities than the DS-Cav1 target or that the affinity of antibodies to UC-3 F target is greater
158 than to DS-Cav1. At most time points and with either target, levels of total anti-pre-F IgG were
159 higher in sera of UC-3 F VLP immunized animals compared to DS-Cav1 F VLP immunized
160 animals (Figure 2, A, B). Titers induced by either pre-fusion F VLPs were higher than that induced
161 by post F VLPs or two consecutive RSV infections (Figure 2). Immunization with different amounts

162 of UC-3 F VLPs made little difference in total anti-pre-F IgG at all times, illustrated by anti-pre-F
163 IgG in sera from individual animals at days 84 and 141 (Figure 2, panels C-F) (Table 2).

164 **Durability of neutralizing antibody (NAb) in dams**

165 Serum NAb titers stimulated in dams by UC-3 F VLPs were higher than titers stimulated
166 by DS Cav1 VLPs (Figure 4 A, B), as we have previously reported (28), and titers after either pre-
167 F VLP immunization were higher than after post-F VLP immunization (Figure 4, panels A-C).
168 Similar to levels of total anti-pre-F IgG, the dose of UC-3 F VLPs had little impact on NAb titers at
169 all times after immunization (Figure 4, Panels F-H).

170 In contrast to total anti-pre-F IgG, NAb titers in the dams after immunization with UC-3 F
171 VLPs remained relatively stable throughout the time course with no statistical differences between
172 time points of day 84 to 277 (Figure 4). However, titers after DS-Cav1 VLP immunization dropped
173 at day 141 and 184, and then recovered by day 231 (Figure 4A and B). Titers after post F VLP
174 immunization dropped slightly at day 184 and then recovered by day 277. Thus, the levels of
175 dams' NAb titers after pre-F VLP immunization did not necessarily track with the titers of total anti-
176 pre-F IgG in the respective animals and levels varied with the immunogen. These results
177 suggested that the NAb generated in the primed dams were a subpopulation of the total anti-
178 pre-fusion F IgG induced by immunization.

179 **Comparison of total serum anti-pre-F IgG in breed 1 and breed 2 pups**

180 Since levels of total anti-pre-F IgG in the sera of dams remained relatively constant from
181 day 84 to day 277 with the exception of a transient drop at day 184 (which may reflect transfer to
182 offspring, Figure 2A and B), we asked if the levels of total maternal pre-F IgG (matAbs) transferred
183 to offspring were similar in breed 1 vs breed 2. Anti-pre-F IgG levels in breed 1 offspring of pre-
184 F VLP immunized dams or RSV immunized dams at four weeks after birth were on average 15 to
185 20% that in the dam sera at day 141 (Figure 5E, F) (Table 3) while that in offspring of dams
186 immunized with post-F VLP was 35% that in dams. However, in breed 2 pups, the total anti-pre-
187 F IgG was, on average, 6 to 11% that in dams at day 141 and 30-53% that in sera of breed 1

188 pups (Figure 5, panels E and F) (Table 3) although dam anti-pre-F IgG did not vary significantly
189 between days 141 and 231. These results suggest that the population of anti-pre-F IgG antibodies
190 in immunized dams is less efficiently transferred to pups in breed 2 compared to breed 1. As in
191 the dam sera, the concentration of UC-3 F VLP used as immunogen had little effect on the pup
192 IgG titers (Figure 5, panels A-D).

193 **Comparisons of matNAb titers in sera of breed 1 and breed 2 pups**

194 The matNAb (maternal neutralizing antibodies) titers in sera of all pups from breed 1 were
195 considerably higher than that in sera of breed 2 pups irrespective of the immunogen used for
196 dams (Figure 6, panels A and B, respectively) and consistent with the differences in total anti-pre-
197 F IgG between these two breeds of pups (Figure 5). In this case the dose of the immunogen in
198 dams made some difference in titers on matNAb in both breeds. The 100 μ g dose of UC-3 F
199 VLPs resulted in the highest mean matNAb titers, however, the mean titers in breed 2 pup sera
200 were considerably lower than those in breed 1 sera, with the mean titer in breed 1 at 7, \log_2 , and
201 in breed 2 at 5, \log_2 . The mean serum matNAb titers in both breeds of offspring of dams
202 immunized with DS-Cav-1 or post F VLPs were considerably lower than titers resulting from
203 immunization with a similar concentration of UC-3 F VLPs.

204 **Comparisons of protection by matAb of breed 1 and breed 2 pups from RSV challenge**

205 Titers of virus in lungs and nasal tissues of pups after RSV challenge directly reflects the
206 extent of protection of the pups by maternal antibodies. The lung and nasal tissue RSV titers in
207 breed 1 pups (Figure 6, panel C and E respectively) clearly demonstrate that all breed 1 offspring
208 of dams immunized with any pre-F VLP were significantly protected from replication of the virus
209 in lung tissue, reducing virus titers by three \log_2 (panel C). However, only UC-3 F VLP
210 immunization resulted in significant protection from replication in nasal tissues (panel E).
211 Immunization with 100 μ g of UC-3 F VLPs resulted in a decrease of two \log_2 of virus (panel E) in
212 nasal tissue, while maternal immunization using DS-Cav1 F or post-F VLP resulted in, at best, a

213 half \log_2 reduction in nasal tissue titer. This result indicated that UC-3 F VLPs immunization
214 conferred more robust protection than DS Cav1 F VLPs consistent with results previously reported
215 (28).

216 In contrast, pups born from breed 2 showed much lower protection from replication of the
217 virus in lung tissue and nasal tissue (Figure 6, panels D and F, respectively). At best, there was
218 a one \log_2 reduction in virus titers in these tissues, a result consistent with the lower levels of
219 NAb in these breed 2 animals. Thus, while total anti-pre-F IgG in dams remained relatively
220 constant, the transfer of matNAbs to their respective pups decreased during a second breeding
221 and correlated with the decrease in protection. This result may reflect an evolution of the
222 properties of dam antibodies, with time after immunization, to populations less efficiently
223 transferred to offspring. Alternatively, placental transfer may not be as efficient in elderly animals.

224 **Durability of Transferred of total anti-pre-F IgG and NAb to offspring.**

225 Since there was significant protection of offspring from RSV challenge four weeks after
226 birth, particularly in breed 1 pups, we determined the durability of this protection by comparing
227 the levels total anti-pre-F IgG antibodies, matNAb, and virus titers in lung and nasal tissue in
228 breed 1 pups at 4 and at 6 weeks after birth. Comparisons of the total anti-pre-F IgG showed
229 levels at 6 weeks of 40 to 61% that at 4 weeks regardless of the dose of antigen in the dams
230 (Figure 7, panels A, B). The mean matNAb titers at 6 weeks after birth were 3 \log_2 lower than at
231 4 weeks after birth (Figure 7, panels C-D). These differences in the matNAb titers translated to
232 different levels of protection at 4 and 6 weeks after birth from RSV challenge. After challenge,
233 RSV titers in lungs or in nasal tissue at 4 weeks after birth were 1-2 \log_{10} lower than titers at 6
234 weeks after birth (Figure 7, panels E-H). Thus, in breed 1 pups, the matNAb titers and levels of
235 protection from an RSV challenge diminished significantly by 6 weeks after birth, however, the
236 matNAb titers in UC-3 VLP-vaccinated animals remain significantly higher and lung and nose
237 RSV titers significantly lower than in control offspring of RSV/mock, RSV/RSV, or unvaccinated

238 dams. Furthermore, the durability of protection of offspring of UC-3 F VLP immunized dams was
239 significantly better than that of offspring of DS Cav1 immunized dams.

240 Breed 2 pups were similarly characterized at 4 weeks and 8 weeks after birth (Figure 8).
241 While levels of total pre-F IgG were surprisingly similar at 4 and 8 weeks (Figure 8, panels A, B)
242 the levels of matNAbs were strikingly different (Figure 8, panels C and D). Breed 2 pups at 8
243 weeks after birth had no detectable matNAb, and were not protected from virus challenge (Figure
244 8, panels F, I). Thus, levels of protection from RSV challenge in these breed 2 pups is strongly
245 correlated with the presence of matNAbs, and their steady decrease with the time after birth to
246 undetectable levels by 8 weeks after birth. This loss of protection was despite the presence of
247 significant levels of total anti-pre-F maternal IgG antibodies remaining in these animals.

248

249 **Discussion**

250 Maternal immunization for protection of offspring from some pathogens, including
251 influenza, tetanus, and pertussis infections, is routinely used (19-22)). We have previously
252 reported that, in the cotton rat model of RSV infection, immunization of dams with virus-like
253 particles assembled with mutation stabilized pre-fusion F proteins as well as wild type G protein
254 robustly protected offspring from RSV replication in lungs and nasal tissues after virus challenge
255 (18, 28). Here our goal was to assess the durability of these protective immune responses in
256 dams through two pregnancies and the durability of transfer of protection to offspring of these two
257 breeding events. A secondary goal was to determine the influence of different F protein stabilizing
258 mutations in induction, durability, and transfer of protective responses to offspring as well as the
259 role of different doses of immunogen on levels of these responses.

260 First, results showed that after a single immunization of RSV primed animals with VLPs
261 during the first pregnancy, the levels of total anti-pre-F IgG in dams remained stable for up to 277-
262 318 days after RSV priming with the exception of a significant but transient drop in those levels
263 just before delivery of offspring of the second breeding, on day 184. This drop in IgG is consistent
264 with the transfer of antibodies to the pups. However, the anti-pre-F IgG levels in dams rebounded
265 to levels before the second pregnancy (day 141) suggesting replenishment by bone marrow
266 associated long-lived plasma cells (LLPC) secreting anti-pre-F IgG. Indeed, these cells were
267 detected in dams on day 318 at the end of the protocol. Thus, levels of these antibodies in
268 immunized dams were maintained for most of the life of the animal.

269 We also found that offspring protection and matNAbs responses induced by UC-3 F VLPs
270 were superior and more durable than those induced by DS Cav1 F VLPs as well as post-F VLPs,
271 confirming our previous reports of the superiority of the UC-3 F VLPs (28). Additional findings
272 reported here are that protective responses in dams did not change significantly or reproducibly
273 with increased doses of immunogen. Furthermore, the results show that immunization with VLPs
274 assembled with F and G proteins resulted in superior protective responses compared to dams

275 infected with one or two doses of RSV, a result that suggests that vaccine candidates may be
276 developed that can provide better protection than a natural RSV infection.

277 Perhaps the most significant finding in this study was that, while offspring of the first
278 breeding of the immunized dams were robustly protected from RSV challenge, the protection
279 afforded to offspring of the second breeding was considerably reduced. Breed 1 pups had
280 significantly higher levels of anti-pre-F IgG and NAb titers as well as sharply decreased levels of
281 RSV in lung and nasal tissue following RSV challenge compared to breed 2 pups. These findings
282 were surprising since the total anti-pre-F IgG levels in the dams were at high levels prior to the
283 second breeding and there was evidence of the transfer of the antibodies to the pups just before
284 the second delivery. In addition, the levels of NAb, at least in UC-3 F VLP immunized dams, were
285 constant well past the second delivery. The implication of this finding is that dam antibodies were
286 much less efficiently transferred to their offspring in the second breeding. Indeed, the mean of
287 levels of anti-pre-F IgG in breed 2 pups was 30-53 % lower than levels in breed 1 pups. This
288 finding suggests that the antibodies in dams evolved in a way to decrease efficiency of placental
289 antibody transfer. Alternatively, placental transfer of antibodies may be less efficient in elderly
290 animals.

291 Time post vaccination could result in changes in the composition of the population of
292 MatAbs transferred. This possibility is suggested by the surprising observation that breed 2 pup
293 sera had similar and significant levels of total anti-pre-F IgG antibodies at 4 and 8 weeks but no
294 matNAbs could be measured at 8 weeks. In addition, in cotton rats as in humans, maternal
295 antibodies, mostly IgA, are transferred to the newborn through lactation (32). Our data would
296 then suggest that the protective antibodies transferred through this route may also be reduced by
297 either consecutive pregnancies, time after immunization, and/or the age of the females.
298 Potentially, maternal vaccination against RSV during each pregnancy will be necessary to boost
299 the generation of protective MatNAbs that can be transferred to offspring of that pregnancy.

300 Studies in humans may shed light on the properties of antibody populations that may
301 change affecting efficiency of placental transport. Human maternal antibodies transferred to the
302 fetus are IgG with a strong preference for IgG1(33-37). Furthermore, there is evidence for
303 subpopulations of IgG1 that are preferentially transferred (38). Antibodies transferred to the fetus
304 contain preferentially an Fc domain that efficiently binds to FcRn (Fc receptor neonate), which is
305 largely responsible for transplacental transit of antibodies (33, 39, 40). In addition, it is reported
306 that antibodies transferred are preferentially those with NK cell activating activity and are
307 preferentially modified with galactose containing oligosaccharide side chains (41, 42). How these
308 properties of maternal antibodies may evolve with time after immunization (or infection),
309 pregnancies, or with maternal age is not clear. Notably, it has been reported that galactose
310 content as well as sialic acid content of the Fc domain of antibodies decreases with age (43) but
311 the mechanisms involved are not well understood. Results presented here, the differential levels
312 of protection transferred to the cotton rat pups in breed 1 and breed 2, are consistent with such
313 an evolution in properties of antibodies in immunized dams to those less compatible with placental
314 transfer. It will be important in considerations of the use of maternal RSV vaccines to determine
315 how a second immunization (boost) of CR dams during a second pregnancy affects the efficiency
316 of transfer of protective antibodies to offspring of that pregnancy.

317

318 **Methods**

319 **Preparation, characterization, and validation of VLP stocks**

320
321 VLPs used as immunogens were based on the core proteins of Newcastle disease virus
322 (NDV) M and NP proteins and contained the RSV F and G glycoproteins (44-46). The RSV
323 proteins were assembled into the VLPs as chimera proteins with the sequences of the ectodomain
324 of RSV F and G glycoproteins fused to the transmembrane and cytoplasmic domains of the NDV
325 F and HN proteins, respectively. Three different VLPs were prepared, each containing the same
326 RSV G chimera protein but with a different mutant F chimera protein. One VLP contained the
327 DS-Cav1 pre-fusion F protein (30), while another VLP contained UC-3 F (30), a pre-fusion F
328 protein with the cleavage site and intervening p27 sequences replaced with a seven-amino acid
329 GS rich linker sequence as well as three point mutations, N67I, S215P, D486N, similar to the SC-
330 TM F protein described by Krarup, et al. (47) A third VLP contained the post-F protein (30) and
331 was used as a control, as previously described. The two pre-fusion F proteins also contained the
332 foldon sequence inserted between the RSV F protein ectodomain and the NDV F protein
333 transmembrane domain to stabilize further the pre-fusion conformation.

334 The VLPs were prepared by transfecting avian cells (ELL-0 from American Type Culture
335 Collection) with cDNAs encoding the NDV M and NP proteins, the G protein chimera, and one of
336 the mutant F chimera proteins (DS Cav1, UC-3 F, or post F). VLPs released into the cell
337 supernatant were purified as previously described (48) and the F and G protein content of purified
338 VLPs were quantified by Western blots and by monoclonal antibody (mAb) binding to the VLPs
339 as previously described (18, 30). VLP stocks were adjusted for equivalent levels of F protein (18,
340 30). The pre-fusion or post fusion conformation of the F protein in the VLPs was validated by
341 assessing the binding of mAbs specific to the pre-fusion form of the F protein to the VLPs as
342 previously reported (18, 30).

343 **Preparation of soluble F proteins**

344 Expi293F cells were transfected with cDNAs encoding the soluble DS-Cav1 pre-F protein
345 or the soluble UC-3 pre-F protein. At six days post transfection, total cell supernatants were
346 collected, cell debris removed by centrifugation, and the soluble polypeptides were purified on
347 columns using the His tag and then the streptavidin tag (18, 49). Purified soluble DS Cav1 pre-F
348 protein and soluble UC-3 pre-F protein efficiently bound to pre-fusion specific mAbs AM14 and
349 D25 (30).

350 **Quantification of NP, M, H/G and VLP associated F proteins or soluble F proteins**

351 For Western blots, proteins were resolved on 8% Bis-Tris gels (NuPage,
352 ThermoFisher/Invitrogen). Quantifications of NP, M, H/G proteins, and RSV F/F proteins in VLPs
353 or in soluble F protein preparations (pre-F, post-F) were accomplished after their separation in
354 polyacrylamide gels followed by silver staining (Pierce Silver Stain, ThermoFisher) or Western
355 blots of the proteins in parallel with protein standards as previously described (18, 49).

356 **ELISA**

357 For determination of anti-pre F protein IgG antibody titers, wells of microtiter plates
358 (ThermoFisher/Costar) were coated with either purified soluble DS Cav1 F protein or soluble UC-
359 3 F protein (30 ng/well) and incubated overnight at 4°C, then blocked with 2% BSA for 16 hours.
360 Different dilutions of sera, in PBS-2% BSA and 0.05% Tween, were added to each well and
361 incubated for 2 hours at room temperature. Wells were then washed with PBS, incubated with
362 chicken anti-cotton rat IgG antibody (Abnova PAB29753) coupled to HRP , and incubated for 1.5
363 hours at room temperature. Bound HRP was detected using TMB (3,3',5,5'-tetramethylbenzidin,
364 ThermoFisher34028) and the reaction was stopped with 2N sulfuric acid. Color was read in
365 SpectraMax Plus Plate Reader (Molecular Devices) using SoftMax Pro software. Amounts of IgG
366 (ng/ml) in each dilution were calculated using a standard curve generated using defined amounts
367 of purified cotton rat IgG.

368 **RSV Neutralization**

369 RSV was grown in Hep2 cells, and RSV plaque assays were accomplished on Hep2 cells as
370 previously described (18, 49). Antibody neutralization assays in a plaque reduction assay have
371 been previously described (49). Neutralization titer was defined as \log_2 of the reciprocal of the
372 dilution of serum that reduced virus titer by 60%.

373 **Animals**

374 *Sigmodon hispidus* cotton rats (CR) were obtained from the inbred colony maintained at
375 Sigmovir Biosystems, Inc (Rockville, MD). All studies were conducted under applicable laws and
376 guidelines and after approval from the Sigmovir Biosystems, Inc. Institutional Animal Care and
377 Use Committee. Animals were housed in large polycarbonate cages and fed a standard diet of
378 rodent chow and water ad libitum. Animals were pre-bled before inclusion in the study to rule out
379 the possibility of pre-existing antibodies against RSV. The colony was monitored for antibodies
380 to paramyxoviruses and rodent viruses and no such antibodies were found. All cotton rats born
381 as a result of breeding during these studies were used for RSV challenge at 4, 6, or 8 weeks of
382 age, as indicated, and are referred to as "pups" or "offspring".

383 **Quantification of bone marrow associated anti-pre-F IgG secreting long lived plasma cells** 384 **(LLPC).**

385 CR bone marrow cells were prepared as previously described (31). To quantify LLPC in
386 bone marrows, wells of ELISpot plates (Millipore) were coated overnight with purified soluble
387 pre-F protein (30 ng/well in PBS). Wells were washed and blocked for one hour in complete
388 media. Four-fold serial dilutions of bone marrow cells were added, in triplicate to pre-coated
389 wells and incubated at 37°C for 6 hours. Plates were washed and blocked overnight in PBS
390 containing 1% BSA. Wells were incubated with HRP conjugated chicken anti-cotton rat IgG
391 (1/2000 dilution of Abnova PAB29753) in PBS containing 1% BSA, incubated at room
392 temperature, washed, incubated AEC substrate (BD Biosciences AEC substrate set, 551951) at

393 room temperature until spots appear. Wells were washed and spots counted using CTL
394 Immunospot S5 (46, 50)

395 **Experimental design**

396 Three-week-old female cotton rats (dams) were tagged and separated into the indicated
397 groups (Figure 1, panel B). Female cotton rats were bled and then the indicated groups were
398 primed by RSV A/Long intranasal infection using a dose of 10^5 PFU/animal in 50 μ l. Eight weeks
399 later (d56), females were paired with RSV negative males ~2 weeks older than the females for
400 mating (breed 1). Females were bled for serum collection at days 70, 84 (just before delivery),
401 141, 184, 231, 277, and 318 post priming. At day 70 different groups of primed and pregnant
402 cotton rats were immunized with UC-3 F VLPs with 25, 75, 100, or 150 μ g total VLP protein/animal
403 (5, 15, 20, or 30 μ g F protein), or mock immunized with PBS buffer (Figure 1). Other groups of
404 pregnant cotton rats were immunized with DS-Cav1 F VLPs or post-F VLPs with 100 μ g total VLP
405 protein/animal (20 μ g F protein) (Figure 1). Dams delivered pups at approximately day 84. Dams
406 were bred again at day 156 without additional immunization (breed 2). Breed 2 pups were
407 delivered on or about day 184. Breed 1 pups were bled and challenged with RSV A/Long (10^5
408 PFU/animal) at 4 or 6 weeks of age. Breed 2 pups were bled and challenged with RSV at 4 or 8
409 weeks after birth. All pups were sacrificed on day 4 post challenge. Pup serum NAb and total
410 anti-pre-F IgG and nose and lung viral titers were measured, as previously described (18). Dams
411 were kept in the study for an additional 134 days after delivery of breed 2 pups for additional
412 serum collection.

413 **Statistical analysis**

414 Statistical analyses (student-*t* test) of data were accomplished using Graph Pad Prism 9
415 software.

416 **Acknowledgements**

417

418 This research was funded by grants AI109926 (J.C.G.B) and AI043896 (TM) from the National
419 Institutes of Health. We thank Jason McLellan and Judy Beeler for F protein mAbs. We thank
420 Steven Hatfield for significant technical help. We thank Mr. Charles Smith, Martha Malache,
421 and Ana Rivera for the animal care service.

564
565

566 **Legend to Figure 1: Experimental design**

567 Panel A shows a diagram of the protocol to assess durability of maternal immunization. Groups
568 of CR were primed with RSV (IN) at day 0. These animals were then bred twice, once at day 56,
569 and the second at day 158. Groups of animals were immunized at day 70 with UC-3 F, DS Cav1
570 F, or post F VLPs. Other groups were infected a second time with RSV or mock immunized.
571 Offspring of dams were challenged with RSV at 4, 6, or 8 weeks after birth. Red arrows show
572 times of serum acquisition. Panel B lists groups of dams (10 CR/group).

573

574 **Legend to Figure 2: Total ng/ml of serum anti-pre-F protein IgG**

575 The concentrations of anti-pre-F serum IgG in different groups of dams immunized with
576 VLPs or RSV were assessed by ELISA using soluble UC-3 F (panels A, C, E) or soluble DS-Cav1 F
577 (panels B, D, F) as target. Serum samples acquired in different groups of animals immunized with
578 VLPs at each time point were pooled (panels A, B) and error bars show mean and standard
579 deviation of three separate determinations. Results from serum in individual animals immunized
580 with different concentrations of UC-3 F VLPs or 100 µg DS Cav1 F VLPs and acquired at days 84
581 or 141 are shown in panels C-F. Mean for each group is shown as a horizontal black line.

582 *p<0.05; **p<0.01; ***p<0.001; ****p<0.0001

583

584 **Legend to Figure 3: Bone marrow associated long-lived plasma cells (LLPC) secreting anti-pre-**
585 **F IgG.**

586 At day 318, bone marrows of dams were acquired and the numbers of cells secreting anti-
587 pre-F IgG were measured as described in Methods. Results from bone marrows of individual
588 animals are shown as log₁₀ of the numbers of positive cells in 10⁶ cells. Immunogen in dams is
589 shown on the x axis. Solid line indicates mean titers in each data set. *p<0.05; **p<0.01.

590

591 **Legend to Figure 4: Neutralization titers in dams**

592 The serum NAb titers in dams, primed with RSV at day 0 and immunized at day 70, at each
593 time point are shown. NAb titers of sera from animals immunized with 100 µg VLP protein are
594 shown in panels A-C while titers in animals immunized with RSV or mock immunized are shown
595 in panels D and E. Panels A-E are presented as violin plots with individual animal data shown.

596 Mean and standard deviation are indicated by solid and dotted black lines, respectively. Panels
597 F-H show results of individual animals immunized with 25, 75, or 150 μ g of UC-3 F VLPs. Mean
598 of each group is shown as a black horizontal bar. Red and green dots: data from sera acquired
599 just before delivery of breed 1 or 2, respectively. * $p < 0.05$; ** $p < 0.01$; *** $p < 0.001$; **** $p < 0.0001$

600

601 **Legend to Figure 5: Comparisons of total anti-pre-F IgG in offspring of immunized dams**

602 Shown are total anti-pre-F IgG (ng/ml) (shown on a \log_{10} scale) in individual offspring of
603 breed 1 (panels A, and C) and breed 2 (panels B, D) dams immunized with 25, 75, 100, and 150
604 μ g of UC-3F VLP, 100 μ g of DS-Cav1 VLPs, 100 μ g post F VLPs, RSV, or mock immunized. Pre-F
605 IgG titers at four weeks after birth were determined using as target in ELISA soluble UC-3 F (panels
606 A, B) or DS Cav1 F (panels C, D). Mean is indicated by horizontal black line. Panels E and F directly
607 compare levels of total anti-pre-F IgG in sera from breed 1 and 2 offspring of dams immunized
608 with 100 μ g of VLPs using soluble UC-3 F or DS Cav1 F or as target, respectively, and shown on a
609 linear scale. Mean and standard deviation are indicated by dashed and dotted black line,
610 respectively. * $p < 0.05$; ** $p < 0.01$; *** $p < 0.001$; **** $p < 0.0001$.

611

612 **Legend to Figure 6: Protective Responses in offspring of immunized dams**

613 Panels A, B: neutralizing antibody titers in sera of individual offspring from breed 1 (panel A) or
614 breed 2 (panel B).

615 Panels C and D: RSV titers in lungs of individual offspring from breed 1 or 2, respectively, after
616 RSV challenge at 4 weeks after birth.

617 Panels E and F: RSV titers in nasal tissue of individual offspring from breed 1 or 2, respectively,
618 after RSV challenge at 4 weeks after RSV challenge. Mean of each data set is indicated by solid
619 black line. * $p < 0.05$; ** $p < 0.01$; *** $p < 0.001$; **** $p < 0.0001$

620

621 **Legend to Figure 7: Durability of protection in breed 1 offspring**

622 Sera and tissues acquired at 4 weeks (panels A, C, E, G) or 6 weeks (panels B, D, F, H) after birth
623 of breed 1 pups were assessed for total anti-pre-F IgG (panels A, B), NAb titers (panels C, D), lung
624 titers (panels E, F) or nasal tissue titers (panels G, H) after RSV challenge; * $p < 0.05$; ** $p < 0.01$;
625 *** $p < 0.001$; **** $p < 0.0001$.

626

627 **Legend to Figure 8: Durability of protection in breed 2 offspring**

628 Sera and tissues acquired at 4 weeks (panels A, C, E, G) or 8 weeks (panels B, D, F, H) after birth
629 of breed 2 pups were assessed for total anti-pre-F IgG (panels A, B), NAb titers (panels C, D), RSV
630 lung titers (panels E, F) or nasal tissue titers (panels G, H) after RSV challenge; **** $p < 0.001$;
631 **** $p < 0.0001$.

632

633 **Legend to Table 1: Total ng/ml anti-pre-F IgG in dam sera**

634 The mean ng/ml of anti-Pre-F I IgG in pools of sera from each group of dams from each
635 time point after RSV priming was measured by ELISA using UC-3 F as target. Data from animals
636 immunized with 100 μ g VLPs as well as RSV/RSV and RSV/Mock groups are shown. Numbers, +/-
637 , below each value are the standard deviation of three separate determinations. Numbers in
638 parentheses are the percent of IgG relative to levels at day 141.

639

640 **Legend to Table 2: Effect of different doses of UC-3 F VLPs on total sera ng/ml anti-pre-F**

641 **IgG**

642 The mean ng/ml of anti-pre-F IgG in pools of sera from each of four groups of UC-3 F VLP
643 immunized dams at each time point after RSV priming was measured in ELISA using UC-3 F as
644 target. Numbers, +/-, below each value are the standard deviations of three separate
645 determinations. Numbers in parentheses are the percent of IgG relative to levels at day 141.

646

647 **Legend to Table 3: Comparisons of ng/ml off sera anti-pre-F IgG in dams and pups**

648 The mean and standard deviations, respectively, of titers of anti-pre-F IgG, measured by
649 ELISA, in each of the 8 groups of dams at day 141 is shown on the first two lines. Lines 3 and 4
650 show means and standard deviations, respectively, of anti-pre-F IgG titers in sera of breed 1
651 offspring of each of the 8 groups of dams at four weeks after birth while lines 5 and 6 show similar
652 data for offspring of breed 2.

653 Line 7 shows breed 1 pup titers as a percent of dam titers at day 141 while line 8 shows breed 2
654 pup titers as a percent of dam titers at day 141.
