1. General Considerations

All air and moisture-sensitive experiments were conducted under dry argon atmosphere using standard Schlenk techniques or an MBraun inert-gas glovebox containing an atmosphere of purified argon. Solvents for air- and moisture-sensitive experiments were purified using a two-column solvent purification system (MBraun-SPS-7) and transferred to the glovebox without exposure to air. Deuterated solvents were degassed and stored over activated molecular sieves prior to use. All chemicals were purchased from Sigma-Aldrich, TCI and ABCR chemicals and used without further purification. $[\text{Co}(\text{NMe}_2\text{PNP})\text{Cl}_2]$ **5** was synthesized according to literature procedures.¹ NMR spectra were recorded on Bruker AV-400 and Bruker AV-500 spectrometers at the indicated temperatures with the chemical shifts (δ) given in ppm relative to TMS and the coupling constants (J) in Hz. The solvent signals were used as references and the chemical shifts converted to the TMS scale (C_6D_6 : $\delta^1\text{H}$ = 7.16 ppm, $\delta^{13}\text{C}$ = 128.1 ppm; toluene-d₈: $\delta^1\text{H}$ = 2.09, 6.98, 7.00, 7.09, $\delta^{13}\text{C}$ = 125.5, 128.3, 129.2, 137.9). For quantification, the NMR samples were measured with a 500 MHz Bruker AVANCE III HD NMR spectrometer equipped with a Prodigy Cryo-Probe. ^{13}C spectra (125.74 MHz) were recorded using a 90° pulse with 1H *inverse gated* decoupling (pulse program zgig). 256 scans were accumulated using a recycling delay of 60 seconds to allow for complete relaxation of the ^{13}C nuclei. Spectra were thoroughly phased and integrated to provide quantitative results as checked by the internal reference. CHN elemental microanalyses were measured at “Mikroanalytisches Labor Kolbe” (c/o Fraunhofer Institut UMSICHT). HR-MS spectra were recorded on a Bruker ESQ3000 spectrometer. Infrared spectra were recorded on a Thermo Scientific Nicolet™ iS5 Spectrometer with an ID7 ATR accessory.

2.3.3 Preparation of **10** from **5**, KO'Bu and PhSiH₃

Phenylsilane (6.3 mg, 0.058 mmol) was added to a mixture of **5** (20.0 mg, 0.029 mmol) and potassium *tert*-butoxide (6.5 mg, 0.058 mmol) in toluene (3 mL). The resulting mixture was stirred for 10 min at room temperature. The volatiles were then removed under vacuum. The residue was washed with pentane (2×5 mL) and dried under reduced pressure. Finally, the product was dissolved in C₆D₆ (0.5 mL) and analyzed by ¹H NMR spectroscopy.

2.3.4 Reaction of **5** and KO'Bu

KO'Bu (3.3 mg, 0.029 mmol) was added to a solution of **5** (10.00 mg, 0.015 mmol) in C₆D₆ (0.5 mL) in an NMR tube at room temperature. The mixture was carefully shaken and analyzed by ¹H NMR spectroscopy after 5 min. The ¹H NMR spectrum indicates that **5** remains present in the reaction mixture.

2.3.5 NMR analysis of the reaction mixture containing **9**, PhSiH₃, and CO₂ under catalytic conditions

A solution of NaBEt₃H in toluene (46 μ L, 0.046 mmol) was added to **5** (15 mg, 0.022 mmol) in toluene-d₈ (0.6 ml), and the mixture was stirred for 5 min at room temperature. PhSiH₃ (27 μ L, 0.22 mmol) was added, and the solution was transferred into an NMR tube. After one freeze-pump-thaw-cycle, CO₂ (1 bar) was added. The tube was shaken carefully, and the mixture was analyzed by ¹H NMR spectroscopy. The ¹H NMR spectra indicate that neither **10** nor **12** formed during the reaction.

3. Computational Details

All calculations were performed with the ORCA program package.⁴⁻⁵ All structures were calculated without any truncations of the ligand. The hybrid functional B3LYP was used for geometry optimizations and frequency calculations⁶⁻⁸ in combination with the atom-pairwise dispersion correction with Becke-Johnson damping D3BJ from Grimme.⁹⁻¹⁰ Key bond lengths and angles of the calculated structure of **5** were compared to the molecular structure determined by X-ray diffraction¹ to justify the functional choice. Several DFT functionals could successfully reproduce the geometrical features within the expected uncertainty of the calculations, as seen in Table S3. To accelerate the calculations, the density fitting (RI-J) and “chain of spheres” (COSX) approximation (RIJCOSX)¹¹ was used with the auxiliary basis set def2/J.¹² The geometry optimizations and frequency calculations were performed with Ahlrichs triple- ζ quality basis set Def2-TZVP for the first coordination sphere (Co, Cl, P, Si, O, N, CO₂, and H), while the triple- ζ quality basis set Def2-SVP was used for all other atoms.¹³ The following thresholds were used for optimizations: energy change tolerance of 1×10^{-6} a.u., root mean square gradient of 3×10^{-5} a.u., a maximum gradient of 1×10^{-4} a.u., root mean square step of 6×10^{-4} a.u. and maximum step of 1×10^{-3} a.u. The DFT integration grid was set to Grid5. Tight convergence criteria (energy tolerance of 1×10^{-8} a.u.) were used for all calculations. The geometry optimizations were performed without constraints. The conductor-like polarizable continuum (CPCM) model was used to describe solvation effects during the geometry optimizations and frequency calculations of the intermediates. Benzene ($\epsilon = 2.28$) was chosen as solvent. Calculations of harmonic vibrational frequencies were performed to ensure that the number of imaginary frequencies is zero for local minima and one for transition states. The zero-point vibrational energies, thermal corrections to the electronic energies (298 K) and the entropy contributions were taken from the frequency calculations. The Gibbs free energies of each structure were corrected to the reference state of 1M by a factor of +1.89 kcal mol⁻¹.

Table S3: Molecular structure of **5** (left) and key bond lengths and angles of the molecular structure of **5** determined by XRD¹ and the calculated geometry obtained with different DFT functionals (def2-TZVP (selected atoms), def-SVP; no solvation model). H atoms were omitted for clarity.

5. Off-cycle intermediates and alternative isomers

The relative energies of complexes **10** and **12** and the alternative isomers **10'**, **12'**, **14'**, **14''**, **20'**, and **20''** were calculated. The Gibbs free energies [kcal mol⁻¹] are displayed in Figure S35 relative to complex **9** (0.0 kcal mol⁻¹).

Scheme S1: Isomers of **10**, **12**, **14**, and **20**.

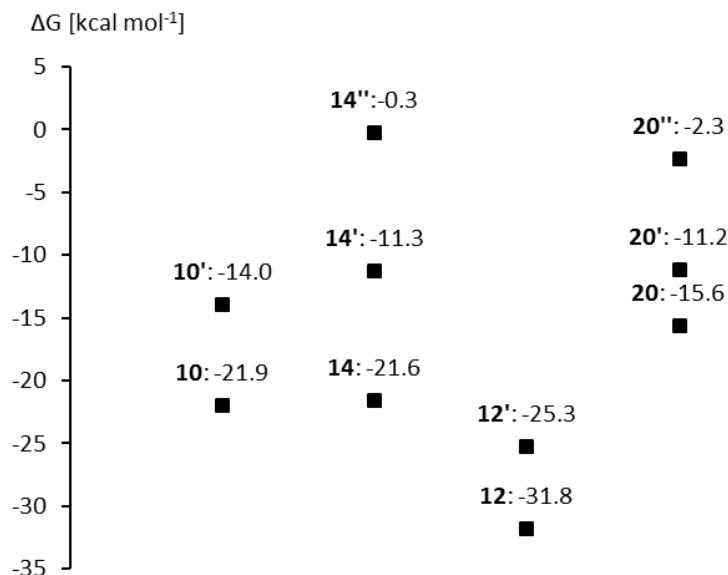

Figure S35: Gibbs free energies [kcal mol⁻¹] relative to **9** (0.0 kcal mol⁻¹) (B3LYP-D3BJ/def2-TZVP (selected atoms), def-SVP) for different isomers of the complexes **10**, **12**, **14**, and **20**.

6. Multiple Si–H activations

The computational mechanistic studies were performed based on the generation of **13** as the product of a single activation of a phenylsilane Si–H bond. This, therefore, constitutes a simplification of the reaction network since subsequent activation of the remaining Si–H bonds of the silylated products is, in theory, possible and since a complex product mixture is observed. Complex **33** forming after oxidative addition of phenylsilyl formate **13** to **11** has a relative Gibbs free energy of -30.6 kcal mol $^{-1}$. The product from the reductive elimination (**34**) has a relative energy of -10.6 kcal mol $^{-1}$. This indicates that this reaction pathway is competing with the oxidative addition of phenylsilane to **11**.

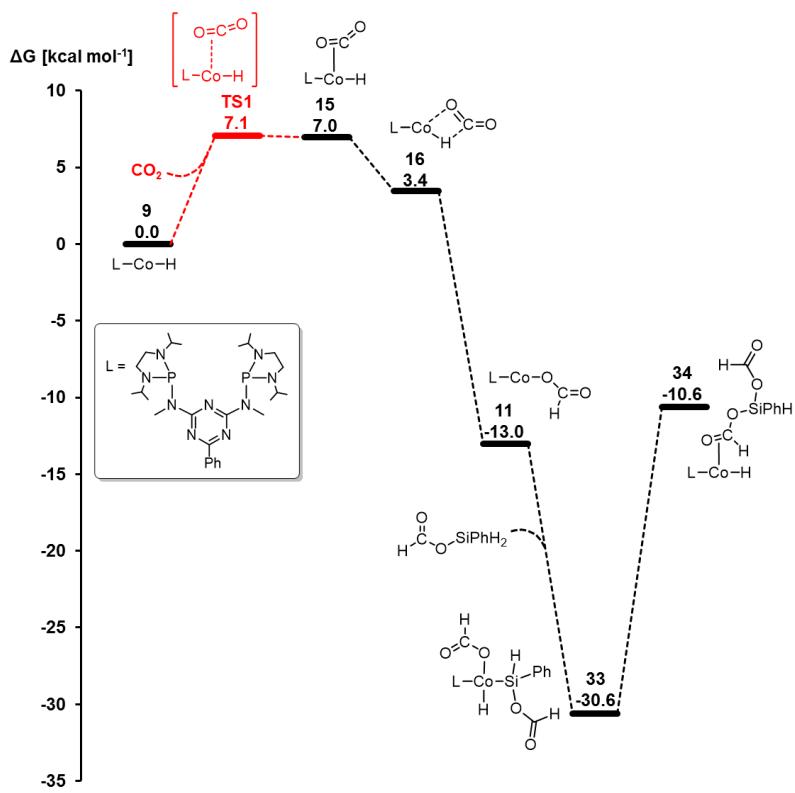

Figure S36: Relative Gibbs free energies [kcal mol $^{-1}$] (B3LYP-D3BJ/def2-TZVP (selected atoms), def-SVP) for the formation of a bis(formyl)silane.

7. Reductive elimination of formic acid

As an additional reaction pathway, we investigated the reductive elimination of formic acid from an alternative isomer **14'**, which is 10.3 kcal mol⁻¹ higher in energy than **14**. Cobalt(I) silyl complex **32** has a relative energy of -0.5 kcal mol⁻¹. Due to the high energy of **14'** compared to **14** and the low thermodynamic driving force of the reaction of **9**, CO₂ and PhSiH₃ to **32** and formic acid, the reaction is considered less favored than the generation of silyl formate **13** from **14**.

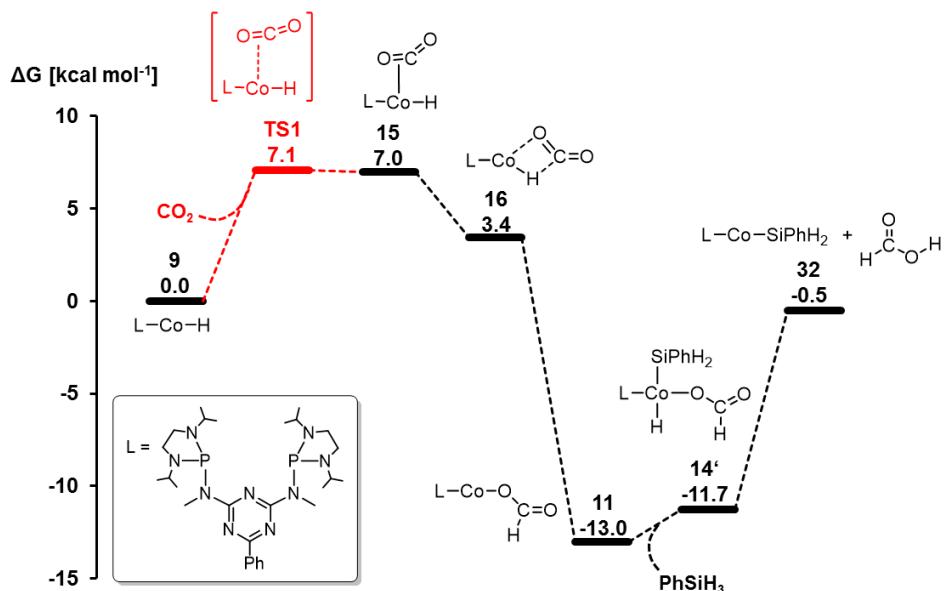

Figure S37: Relative Gibbs free energies [kcal mol⁻¹] (B3LYP-D3BJ/def2-TZVP (selected atoms), def-SVP) for the generation of **32** and formic acid from **9**, CO₂, and PhSiH₃.

8. Kinetic Simulations

The graphical representations of the product concentrations were obtained after microkinetic modeling.¹⁴ Rate constants for each step were obtained with the Eyring equation using the energy difference between the connected intermediates and transition states. The free energy barriers of reactions that do not pass a transition state were neglected.

$$k = \frac{k_B T}{h} \exp\left(-\frac{\Delta G^\#}{RT}\right)$$

To simplify the reaction network, we only considered the insertion into the phenylsilane [Si]–H bond since under catalytic conditions, phenylsilane is in high excess compared to CO₂ (Figure 12). Furthermore, complexes **10** and **12** have a low relative energy ($-21.9\text{ kcal mol}^{-1}$ and $-31.8\text{ kcal mol}^{-1}$) and may supposedly accumulate during the catalytic reaction. However, under operative conditions, **10** or **12** were not observed. Therefore, their formation was not included in the simulation.

Kinetic simulations were performed using the *Tenua* program (© 2021, Daniel Wachsstock). In the case of 1 bar pressure, the starting concentrations of phenylsilane, catalyst **9**, and CO₂ were set to 5M, 0.05M, and 1M, respectively. The CO₂ concentration was calculated from the ratio of phenylsilane and CO₂ in the reaction, and thus, the transfer from the gas phase into the liquid phase was not considered. In the case of 40 bar pressure, the CO₂ concentration was increased to 40M. The time span and the simulation accuracy ε were varied between 50 – 100 s and $\varepsilon = 1 \times 10^{-6}$ and $\varepsilon = 1 \times 10^{-5}$.
