#### Abstract

This work proposes a soft switching approach for dual-boost converter using an auxiliary resonant circuit. The topology is composed of a general dual-boost converter and an auxiliary resonant circuit including one switch, inductor, capacitor and diode. The auxiliary resonant circuit helps the main switch to operate under ZVT and ZCS conditions. The auxiliary switch also operates at soft switching mode. Furthermore, the proposed circuit removes the voltage stress on the main and auxiliary switches. Under soft switching conditions the efficiency of the converter increases. The converter has various advantages compared with the conventional boost converters as higher boost rate with low duty cycle, lower voltage stress on components and higher efficiency.

Keywords: Zero Voltage Transition, Dual-Boost Converter, Boost Converter.

## I. INTRODUCTION

DC-DC converters controlled by Pulse Width Modulation technique have a wide range of application areas. Operating the converter at high frequency decreases the converter volume and increases the power density of converter. However, increasing the operating frequency increases the switching losses and the Electromagnetic Interference (EMI) resulting reduction in efficiency of converter [1]. Basically, switching losses are composed of switching losses of switches due to overlapping of voltage and current, loss of diodes due to reverse recovery phenomenon and discharge loss of the parasitic capacitor [2].

To reduce the switching losses several suppressing cells are made as RC/RCD, polar/non-polar, resonance/non-resonant and active/passive cells. The switching losses are greatly reduced by zero voltage switching method (ZVS) and the zero current switching (ZCS) method.

There have been published many papers about boost converter with active soft-switching methods. Boost type converter switching at zero voltage (ZVT) is one of the soft switching techniques given in [3].

There are methods given in [3], [4] and [5] in which the snubber cells cannot eliminate all the switching losses.

In [5-7] there are used multiple inductors that increase the volume and decrease the power density of the converter.

Soft switching techniques used in [6] and [8] reduces the losses but cannot remove the voltage stress of main and auxiliary switches.

The turn on and turn off losses are reduced in [9], but due to several numbers of elements the volume of the converter increases.

In another study [10] there are used more than one switch that increases the cost of the converter [10].

In the study given in [11] the active snubber circuit provides zero voltage transition modes for the main switch. There is no voltage and current stress on the main diode.

This work proposes a soft switching dual-boost converter that is able to turn on both the active power switches at zero voltages to reduce their switching losses and evidently raise the conversion efficiency. In this study dual-boost converter circuit is operating under soft switching technique and the efficiency of the converter increases by reducing the switching losses. The problem of voltage stress is also eliminated. The operation principles of the converter and the conditions for realization of soft switching are analyzed in detail, simulation analysis performed using PSpice is given. The simulation results show that all the switches are operating at soft switching state and the efficiency of the converter is improved.

## II. CIRCUIT CONFIGRATION

Figure 1 represents the circuit configuration of the proposed dual-boost pulse-width modulation (PWM) converter.

Figure 1. Proposed soft switched dual-boost DC/DC converter

The converter consists of one switch; two boost inductors $\mathrm{L}_{1}$ and $\mathrm{L}_{2}$; two diodes $\mathrm{D}_{1}$ and $\mathrm{D}_{2}$; and capacitors $\mathrm{C}_{\mathrm{i}}$ and $\mathrm{C}_{\mathrm{o}}$. Except the output capacitance of the converter, the other components of the converter constitute the auxiliary circuit. $\mathrm{M}_{\mathrm{a}}, \mathrm{D}_{\mathrm{r} 1}, \mathrm{D}_{\mathrm{r} 2}$, and $\mathrm{Dr}_{3}$ represent the auxiliary switch and diodes, respectively. The inductor and capacitor of proposed auxiliary circuit are presented by $L_{r}$ and $C_{r}$, respectively. $D_{m 1}$ is the intrinsic parallel diode of MOSFET $\mathrm{M}_{1}$ and the snubber capacitance, $\mathrm{C}_{\mathrm{s}}$ is common for the main switch $\mathrm{M}_{1}$.

## III. CIRCUIT OPERATION ANALYSIS

The following assumptions are made in analysis of the converter.

- The output capacitor $C_{o}$ is large enough to neglect reasonably the output voltage ripple and consider a constant level output voltage.
- The forward voltage drops on MOSFET $\mathrm{M}_{1}, \mathrm{M}_{\mathrm{a}}$ and diodes $\mathrm{D}_{1}$ and $\mathrm{D}_{2}$ are neglected.
- Inductors $L_{1}$ and $L_{2}$ are large and equal.
- The components of the converter are ideal.

The active switch, $\mathrm{M}_{1}$ is operated with pulse-widthmodulation (PWM) control signals. This is gated with identical frequency and duty ratio. The operation of the converter can be divided into seven modes, the equivalent circuits and the theoretical waveforms are illustrated in Figures 2 and 3.

## A. Mode 1

Prior to this mode, the main switch $\mathrm{M}_{1}$ and the auxiliary switch $M_{a}$ are in the off state and output diode $D_{r 2}$ is conducting. At the beginning of this mode, $M_{a}$ is turned on. The resonant inductor $\left(\mathrm{L}_{\mathrm{r}}\right)$ current starts to rise through the path of $\mathrm{V}_{\text {source }}-\mathrm{L}_{1}-\mathrm{L}_{2}-\mathrm{L}_{\mathrm{r}}-\mathrm{M}_{\mathrm{a}}$. Since the rise rate of this current is limited by $L_{r}$, the devices $D_{1}$ and $M_{a}$ are turned on under soft switching. The voltage across $\mathrm{C}_{\mathrm{s}}$ is nearly equal to the output voltage $\left(\mathrm{V}_{\mathrm{o}}\right)$ in this interval and the initial voltage across the $\mathrm{C}_{\mathrm{r}}$ is nearly equal to zero. During this time interval, the voltage across $\mathrm{C}_{\mathrm{r}}$ and current of $L_{r}$ can be expressed as: $t_{0}<t<t_{1}$
$\dot{I}_{\text {Lr }}(\mathrm{t})=\frac{\mathrm{Vcs}}{\mathrm{Lr}}\left(\mathrm{t}_{1}-\mathrm{t}_{0}\right)=\frac{\mathrm{Vo}}{\mathrm{Lr}}\left(\mathrm{t}-\mathrm{t}_{0}\right)$
$\mathrm{V}_{\mathrm{Cr}}(\mathrm{t})=0$
$\left(\mathrm{t}_{1}-\mathrm{t}_{0}\right)=\Delta \mathrm{t}_{1}=\frac{\mathrm{iL} 1 * \mathrm{Lr}}{\mathrm{Vo}}$
$\mathrm{I}_{\mathrm{o}}(\mathrm{t})=\mathrm{I}_{\mathrm{LI}}-\mathrm{I}_{\mathrm{Ci}}-\mathrm{I}_{\mathrm{L} r}$

## B. Mode 2

$\mathrm{M}_{\mathrm{a}}$ current reaches $i_{\mathrm{L} 1}$ and output current falls to zero at $t=t_{l}$. The snuber capacitor $\left(\mathrm{C}_{\mathrm{s}}\right)$ begins to discharge and
the current in $L_{r}$ increases because of the resonance between $\mathrm{L}_{\mathrm{r}}$ and $\mathrm{C}_{\mathrm{s}} . \mathrm{C}_{\mathrm{s}}$ is discharged until its voltage reaches zero at $\mathrm{t}_{2}$. The resonant time period of this interval, the current of $L_{r}$ and voltage across $\mathrm{C}_{\mathrm{s}}$ are given by; $\mathrm{t}_{1}<\mathrm{t}<\mathrm{t}_{2}$
$\mathrm{I}_{\mathrm{Lr}}(\mathrm{t})=\mathrm{i}_{\mathrm{L} 1}+\frac{\mathrm{Vo}}{\mathrm{Z} 1} * \operatorname{Sin} \omega_{1}\left(\mathrm{t}-\mathrm{t}_{1}\right)$
$\mathrm{V}_{\mathrm{Cs}}(\mathrm{t})=\mathrm{V}_{\mathrm{o}} \operatorname{Cos} \omega_{1}\left(\mathrm{t}-\mathrm{t}_{1}\right)$
$\left(\mathrm{t}_{2}-\mathrm{t}_{1}\right)=\Delta \mathrm{t}_{2}=\frac{\pi}{2} \sqrt{\operatorname{LrCs}}$
$\omega_{1}=1 / \sqrt{\operatorname{LrCs}}$ and $Z=\sqrt{\operatorname{LrCs}}$

## C. Mode 3

At $t=t_{2}$, the main switch and $D_{2}$ are in the off state and auxiliary switch and $D_{1}$ are in the on state. Auxiliary switch conducts the current in $\mathrm{L}_{\mathrm{r}}$. At the beginning of this mode current of snubber capacitor $\mathrm{C}_{\mathrm{s}}$ is completely exhausted and the $L_{r}$ current reaches its maximum rate.

At this interval, the current in $L_{r}$ flows in $L_{r}-M_{a}$ and body diodes of the main switches. The voltage across $C_{r}$ is discharged nearly to zero before $\mathrm{t}_{2}$. The maximum current of $\mathrm{L}_{r}$ can be equated as;
$\dot{\mathrm{I}}_{\mathrm{Lr}}(\mathrm{t})=\mathrm{I}_{\mathrm{Lrmax}}=\mathrm{I}_{\mathrm{L} 1}+\mathrm{V}_{\mathrm{o}} / \mathrm{Z}_{1}$
$\mathrm{V}_{\mathrm{Cr}}(\mathrm{t}) \cong 0$
At this mode, the main switch should be switched to satisfy the ZVT condition. By assuming the average inductor current of $L_{1}$ is the half of the input current at steady state, the delay time for $M_{1}, t_{d}$ can be expressed as; $\mathrm{t}_{\mathrm{d}}=\Delta \mathrm{t}_{1}+\Delta \mathrm{t}_{2}=\frac{\operatorname{Lin} * \operatorname{Lr}}{\mathrm{Vo}}+\frac{\pi}{2} \sqrt{\operatorname{LrCs}}$

Additionally, the current through inductors will start to increase linearly according to;
$\mathrm{I}_{\mathrm{L} 1}=\frac{\mathrm{Vs}}{\mathrm{L} 1+\mathrm{Lr}}\left(\mathrm{t}_{3}-\mathrm{t}_{2}\right) \cong \frac{\mathrm{Vs}}{\mathrm{L} 1}\left(\mathrm{t}_{3}-\mathrm{t}_{2}\right)$
$\mathrm{I}_{\mathrm{L} 2}=\frac{\mathrm{VCi}}{\mathrm{L} 2+\mathrm{Lr}} \mathrm{t} \cong \frac{\mathrm{VCi}}{\mathrm{L} 2} \mathrm{t}$

## D. Mode 4

At the start of this interval, $\mathrm{M}_{\mathrm{a}}$ is turned off and the main switch is turned on at the same time. At this mode, the main switche, $\mathrm{M}_{1}$ and $\mathrm{L}_{\mathrm{r}}$ conduct the input current together. At the end of this mode the current of $\mathrm{L}_{\mathrm{r}}$ and $\mathrm{L}_{1}, \mathrm{~L}_{2}$ reaches zero.
$\mathrm{I}_{\mathrm{L} 1}=\frac{\mathrm{Vs}-\mathrm{Vo}}{\mathrm{L} 1+\mathrm{Lr}}\left(\mathrm{t}_{4}-\mathrm{t}_{3}\right) \cong \frac{\mathrm{Vs}}{\mathrm{L} 1} \quad\left(\mathrm{t}_{4}-\mathrm{t}_{3}\right)$
$\mathrm{I}_{\mathrm{L} 2} \cong \frac{\mathrm{Vci}}{\mathrm{L} 2}\left(\mathrm{t}_{6}-\mathrm{t}_{4}\right)$

## E. Mode 5

This interval is composed of two equivalent circuit. The energy is stored in the boosting inductor $\mathrm{L}_{1}$ through the loop of $\mathrm{V}_{\text {source }}-\mathrm{L}_{1}-\mathrm{D}_{1}-\mathrm{M}_{1}$ and stored in the boosting inductor $\mathrm{L}_{2}$ through the loop of $\mathrm{C}_{\mathrm{i}}-\mathrm{L}_{2}-\mathrm{M}_{1}$. The energy is transferred to the load through discharging capacitor, $\mathrm{C}_{0}$. The current of $L_{1}$;
$\mathrm{I}_{\mathrm{L} 1}=\frac{\mathrm{Vs}}{\mathrm{L} 1}\left(\mathrm{t}_{5}-\mathrm{t}_{4}\right)$

## F. Mode 6

At $t_{5}$, the current of main switch falls to zero and voltage across of $\mathrm{M}_{1}$ and $\mathrm{C}_{\mathrm{s}}$ go up to output voltage $\mathrm{V}_{\mathrm{o}}$. At the end of this interval the current of $L_{r}$ starts to increase.

## G. Mode 7

At a certain moment $\mathrm{t}_{6}, \mathrm{D}_{2}$ and main switch are turned off. $\mathrm{D}_{2}, \mathrm{D}_{\mathrm{r} 1}$ and $\mathrm{D}_{\mathrm{r} 2}$ are turned on. The inductor currents $\mathrm{I}_{\mathrm{L} 1}$ and $\mathrm{I}_{\mathrm{L} 2}$ at the that moment have reached peak values. The stored energy is supplied to load through diodes $\mathrm{D}_{2}$, $\mathrm{D}_{\mathrm{r} 1}$ and $\mathrm{D}_{\mathrm{r} 2}$. As a result, the current through the inductors $\mathrm{I}_{\mathrm{L} 1}$ and $\mathrm{I}_{\mathrm{L} 2}$ will start to decrease linearly according to;

$\mathrm{I}_{\mathrm{L} 1}=\frac{\mathrm{Vs}-\mathrm{Vci}}{\mathrm{L} 1}\left(\mathrm{t}_{6}-\mathrm{t}_{7}\right)$
$\mathrm{I}_{\mathrm{L} 2}=\frac{\mathrm{Vci}-\mathrm{Vo}}{\mathrm{L} 2+\mathrm{Lr}}\left(\mathrm{t}_{6}-\mathrm{t}_{7}\right)$
Current $C_{i}$ is inversed again, and $C_{i}$ is now charging until $D_{1}$ is turned on again and the cycle with its seven intervals is repeated.

## IV. CİRCUIT DESIGN AND SELECTION OF COMPONENTS

The boost converter is a high-efficiency step-up DC/DC switching converter. The converter uses a switch to transfer power through pulse-width modulation technique. This section presents a design procedure for the proposed soft switched dual-boost converter operating in continuous conduction mode (CCM). In the periodic switching scheme with period $T$, the average voltage across the inductor must be zero. The relationship of voltage and current for an inductor is
$\mathrm{V}_{\mathrm{L}}=\mathrm{L} \frac{\mathrm{diL}}{\mathrm{dt}}$,
$\dot{\mathrm{I}}_{\mathrm{L}}(\mathrm{t})=\frac{1}{\mathrm{~L}} \int_{0}^{\mathrm{t}} \mathrm{VL}(\mathrm{t}) \mathrm{dt}+\dot{\mathrm{I}}_{\mathrm{L}}(0)$,
$\dot{\mathrm{I}}_{\mathrm{L}}(\mathrm{t})=\frac{1}{\mathrm{~L}} \int_{\mathrm{t} 0}^{\mathrm{t}} \mathrm{VL}(\mathrm{t}) \mathrm{dt}+\dot{\mathrm{I}}_{\mathrm{L}}\left(\mathrm{t}_{\mathrm{o}}\right)$,
$\dot{\mathrm{I}}_{\mathrm{L}}\left(\mathrm{T}+\mathrm{t}_{\mathrm{o}}\right)=\frac{1}{\mathrm{~L}} \int_{\mathrm{t} 0}^{\mathrm{T}+\mathrm{t}} \mathrm{VL}(\mathrm{t}) \mathrm{dt}+\dot{\mathrm{I}}_{\mathrm{L}}\left(\mathrm{t}_{0}\right)$,
$\dot{\mathrm{I}}_{\mathrm{L}}\left(\mathrm{T}+\mathrm{t}_{\mathrm{o}}\right)-\dot{\mathrm{I}}_{\mathrm{L}}\left(\mathrm{t}_{\mathrm{o}}\right)=\frac{1}{\mathrm{~L}} \int_{\mathrm{t} 0}^{\mathrm{T}+\mathrm{t}} \mathrm{VL}(\mathrm{t}) \mathrm{dt}$.
$\mathrm{i}(\mathrm{t})=\mathrm{i}(\mathrm{t}+\mathrm{T}), \quad \mathrm{t}=\mathrm{t}_{\mathrm{o}}$, and $\mathrm{V}_{\mathrm{L}}=\frac{1}{\mathrm{~L}} \int_{\mathrm{t} 0}^{\mathrm{T}+\mathrm{t}} \mathrm{VL}(\mathrm{t}) \mathrm{dt}=0$
According to the voltage second product,
$\mathrm{V}_{\mathrm{s}} * \mathrm{t}_{\text {on }}=\left(\mathrm{V}_{\mathrm{Ci}}-\mathrm{V}_{\mathrm{s}}\right) * \mathrm{t}_{\text {off }}$ or $\quad \mathrm{V}_{\mathrm{s}} \mathrm{T}=\mathrm{V}_{\mathrm{Ci}} \mathrm{t}_{\mathrm{off}}$
$\mathrm{V}_{\mathrm{Ci}}=\frac{\mathrm{T}}{\text { toff }} \mathrm{V}_{\mathrm{S}}=\frac{\mathrm{T}}{\mathrm{T}-\text { ton }} \mathrm{V}_{\mathrm{S}}$
$\mathrm{V}_{\mathrm{Ci}}=\frac{1}{1-(\text { Daux }+ \text { Dmain })} \mathrm{V}_{\mathrm{s}}$,
$D_{\text {eff }}=D_{\text {aux }}+D_{\text {main }}$
$D_{\text {main }}$ is duty cycle of the main switch and $\mathrm{D}_{\text {aux }}$ is the duty cycleof the auxiliary switch. The same procedure is used to find the relation between the output voltage $\mathrm{V}_{\mathrm{o}}$ and the first stage output $\mathrm{V}_{\mathrm{C}}$ :
$\mathrm{V}_{\mathrm{Ci}} \mathrm{t}_{\mathrm{on}}=\left(\mathrm{V}_{\mathrm{o}}-\mathrm{V}_{\mathrm{Ci}}\right) \mathrm{t}_{\mathrm{off}}$,
$\mathrm{V}_{\mathrm{Ci}}\left(\mathrm{t}_{\mathrm{on}+} \mathrm{t}_{\text {off }}\right)=\mathrm{V}_{\mathrm{o}} \mathrm{t}_{\text {off }}$,
$\mathrm{V}_{\mathrm{o}}=\frac{\mathrm{T}}{\text { toff }} \mathrm{V}_{\mathrm{Ci}}=\frac{\mathrm{T}}{\mathrm{T}-\text { ton }} \mathrm{V}_{\mathrm{Ci}}$,
$\mathrm{V}_{\mathrm{o}} \cong \frac{1}{1-(\text { Daux }+ \text { Dmain })} \mathrm{V}_{\mathrm{Ci}} \cong \frac{1}{1-\text { Deff }} \mathrm{V}_{\mathrm{Ci}}$
$\mathrm{V}_{\mathrm{o}}=\frac{1}{1-\text { Deff }} \mathrm{V}_{\mathrm{Ci}}=\frac{1}{(1-\text { Deff } 2 .} \mathrm{V}_{\mathrm{s}}$
The gain of the dual-boost DC-DC converter will be
$\mathrm{V}_{\mathrm{o}} \cong \frac{1}{(1-\text { Deff })} \mathrm{V}_{\mathrm{s}}$.

To achive the zero voltage transition, a delay time ( $\mathrm{T}_{\text {delay }}$ ) of main switch PWM is required. The minimum
delay time must be satisfied the following equation. The time is consisted of the resonant time between $L_{r}$ and $C_{s}$ and the time that the resonant inductor current equals the input current.
$\mathrm{T}_{\mathrm{d}} \geq \frac{\operatorname{Iin} * \operatorname{Lr}}{\text { Vo }}+\frac{\pi}{2} \sqrt{\operatorname{LrCs}}$
It is seen from equation (32) that $\mathrm{T}_{\mathrm{d}}$ depends on $\mathrm{V}_{\mathrm{o}}$, $\mathrm{I}_{\mathrm{in}}, \mathrm{L}_{\mathrm{r}}$ and $\mathrm{C}_{\mathrm{s}}$. During the delay time, the auxiliary switch is turned on.

The input current ripple $\Delta \mathrm{I}_{\mathrm{L}}$ on each of the boost inductors can be denoted as:
$\Delta \mathrm{I}_{\mathrm{L}} \cong \Delta I_{L l}=\frac{\text { Deff }}{L 1 * f} V_{s,}$
An ideal output capacitor the output voltage ripple can be determined as:
$\Delta V o=\frac{I o * D e f f}{C * f}$,

Figure 4. Voltage conversion ratio.

## V. SIMULATION

In this section, simulations are carried out to verify the theoretical analysis given in the previous sections. Since the PSpice simulation program includes models of the real components, the proposed topology is firstly simulated via this program and the simulation results of the proposed topology are shown in the following figures. The converter design specifications are considered for medium power sources. Since the output voltage generated by the photovoltaic arrays and the fuel stack sources is relatively low, their output voltage is generally increased via conventional boost or dual-boost type dc-dc converters to the required voltage level. The converter specifications consist of,

Output power: $\mathrm{P}_{\mathrm{o}}=600 \mathrm{~W}$,
Output voltage ripple, $\Delta V o=\% 2$,
Input current ripple, $\Delta I_{L}=\% 15$,
Switching frequency: $\mathrm{f}_{\mathrm{s}}=50 \mathrm{kHz}$,

| Table 1. Components values for the simulation |  |  |
| :--- | :--- | :--- |
| Components | Symbols | Parameters |
| Input voltage | $\mathrm{V}_{\text {source }}$ | 100 V |
| Output voltage | $\mathrm{V}_{\text {output }}$ | 300 V |
| Switching frequency | $\mathrm{f}_{\text {sw }}$ | 50 kHz |
| Main inductances | $\mathrm{L}_{1}$ and $\mathrm{L}_{2}$ | 300 uH |
| Auxiliary inductance | $\mathrm{L}_{\mathrm{r}}$ | 1 uH |
| Auxiliary capacitance | Cr | 5 nF |
| Snubber capacitance | $\mathrm{C}_{\mathrm{s}}$ | 1 nF |
| Input capacitance | $\mathrm{C}_{\mathrm{i}}$ | 30 uF |
| Output capacitance | $\mathrm{C}_{\mathrm{o}}$ | 50 uF |
| Main switch | $\mathrm{M}_{1}$ | $\mathrm{IRF} 250-30 \mathrm{~A}$ |
| Auxiliary switch | $\mathrm{M}_{\mathrm{a}}$ | IRF350-14A |
| Main diodes | $\mathrm{D}_{1}$ and $\mathrm{D}_{2}$ | MUR810 |
| Auxiliary diodes | $\mathrm{D}_{\mathrm{r} 1}, \mathrm{D}_{\mathrm{r} 2}, \mathrm{D}_{\mathrm{r} 3}$ and $\mathrm{D}_{\mathrm{m}}$ | MUR810 |
| Output power | $\mathrm{P}_{\mathrm{o}}$ | 600 W |

Figure 6. Simulation waveforms of the voltage and current of the auxiliary switch $\mathrm{M}_{\mathrm{a}}\left(\mathrm{V}_{\mathrm{DMa}} / 10, \mathrm{I}_{\mathrm{DMa}}\right.$ and $\left.\mathrm{P}_{\mathrm{o}}=600 \mathrm{~W}-\mathrm{V}_{\mathrm{o}}=300 \mathrm{~V}\right)$

Figure 7. Simulation waveforms of the voltage and current of the main switch $\mathrm{M}_{1}\left(\mathrm{~V}_{\mathrm{D}} / 10, \mathrm{I}_{\mathrm{DM}}\right)$ under soft switching condition. $\left(\mathrm{P}_{\mathrm{o}}=600 \mathrm{~W}-\mathrm{V}_{\mathrm{o}}\right.$ $=300 \mathrm{~V}$ )

Figure 8. Simulation waveforms of the voltage and current of the main switch $\mathrm{M}_{1}\left(\mathrm{~V}_{\mathrm{D}} / 10, \mathrm{I}_{\mathrm{DM} 1}\right)$ under soft switching condition turn on. $\left(\mathrm{P}_{\mathrm{o}}=\right.$ $600 \mathrm{~W}-\mathrm{V}_{\mathrm{o}}=300 \mathrm{~V}$ )

Figure 9. Simulation waveforms of the voltage and current of the main switch $\mathrm{M}_{1}\left(\mathrm{~V}_{\mathrm{DM1}}, \mathrm{I}_{\mathrm{DM1}}\right)$ under soft switching condition turn off $\left(\mathrm{P}_{\mathrm{o}}=600\right.$ $\mathrm{W}-\mathrm{V}_{\mathrm{o}}=300 \mathrm{~V}$ )

Figure 10. Simulation waveforms of the voltage and current of the main diode D1 $\left(\mathrm{V}_{\mathrm{D} 1}, \mathrm{I}_{\mathrm{D} 1} * 5\right)$ under soft switching condition $\left(\mathrm{P}_{\mathrm{o}}=600 \mathrm{~W}-\mathrm{V}_{\mathrm{o}}\right.$ $=300 \mathrm{~V}$ )

Figure 11. Simulation waveforms of the voltage and current of the main diode $\mathrm{D} 2\left(\mathrm{~V}_{\mathrm{D} 2}, \mathrm{I}_{\mathrm{D} 2} * 5\right)$ under soft switching condition $\left(\mathrm{P}_{\mathrm{o}}=600 \mathrm{~W}-\mathrm{V}_{\mathrm{o}}\right.$ $=300 \mathrm{~V}$ )

Figure 12. Simulation waveforms of the voltage and current of the auxiliary diode $\operatorname{Dr} 2\left(\mathrm{~V}_{\mathrm{Dr} 2} / 15, \mathrm{I}_{\mathrm{Dr} 2}\right)$ under soft switching condition $\left(\mathrm{P}_{\mathrm{o}}=\right.$ $600 \mathrm{~W}-\mathrm{V}_{\mathrm{o}}=300 \mathrm{~V}$ )

Figure 13. Simulation waveforms of the voltage and current of the auxiliary diode $\operatorname{Dr} 3\left(\mathrm{~V}_{\mathrm{Dr} 3} / 20, \mathrm{I}_{\mathrm{Dr} 3} * 5\right)$ under soft switching condition ( $\mathrm{P}_{\mathrm{o}}=600 \mathrm{~W}-\mathrm{V}_{\mathrm{o}}=300 \mathrm{~V}$ )

From the simulation results given in figures 12 and 13 , it is seen that the main switch $\mathrm{M}_{1}$ is turned on perfectly with ZVT and turned off under near ZCS. Figure 9 shows auxiliary switch, $\mathrm{Ma}_{\mathrm{a}}$ which is turned on and off under soft switching. Also, the devices $\mathrm{D}_{1}, \mathrm{D}_{2}$, $\mathrm{D}_{\mathrm{r} 1}, \mathrm{D}_{\mathrm{r} 2}$ and $\mathrm{D}_{\mathrm{r} 3}$ operate under soft switching conditions. The losses of the semiconductor devices and the total efficiencies of the circuits for hard switching and the proposed soft switching cases are summarized for various loads as given in Table 2.

Table 2. Losses of the semiconductor devices and total efficiencies of the circuits in the hard switching and the proposed soft switching converter

| Vsource: $\mathbf{1 0 0} \mathrm{V}$, Vo: $\mathbf{3 0 0}$, Freq: $\mathbf{5 0} \mathbf{~ k H z}$ |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| DC-DC DUALBOOST CONVERTER |  |  |  |  |  |  |  |
| $\begin{gathered} \text { LOAD } \\ \% \end{gathered}$ | HARD OR SOFT | POWERLOSSES |  |  | INPUT POWER | OUTPUT POWER | efficiency <br> \% |
|  |  | MAIN switch | AUXILIARY SWITCH | DIODES AND OTHER |  |  |  |
| 20 | HARD | 3,3 | NONE | 7,3 | 130,6 | 120 | 91,80 |
|  | SOFT | 1,1 | 1,95 | 8,0 | 11,1 | 120 | 91,50 |
| 25 | HARD | 4,0 | NONE | 5,4 | 159,4 | 150 | 94,10 |
|  | SOFT | 1,0 | 2 | 5,8 | 161,6 | 150 | 92,80 |
| 50 | HARD | 7,6 | NONE | 7,8 | 315,4 | 300 | 95,10 |
|  | SOFT | 3,4 | 4,7 | 9,0 | 317,1 | 300 | 94,60 |
| 75 | HARD | 13,2 | NONE | 9,1 | 472,3 | 450 | 95,20 |
|  | SOFT | 5,4 | 8,1 | 6,5 | 470,0 | 450 | 95,75 |
| 100 | HARD | 20,3 | NONE | 10,8 | 631,1 | 600 | 95,00 |
|  | SOFT | 9,2 | 9,27 | 8,3 | 626,7 | 600 | 95,70 |

At 450 W output power in the hard switching operation the main switch loss is about $13,2 \mathrm{~W}$ and this loss is equal $\% 59,1$ of total loss of circuit. At 450 W output power in the proposed soft switching converter, the main
switch loss is about 5,4 W and this loss is equal $\% 27$ of total loss of circuit.

Figure 14. Overall efficiency curves of the hard switching and the proposed soft switching converters comparatively

## VI. CONCLUSION

In this paper, a soft switching dual-boost converter using an auxiliary resonant circuit is proposed. Operation modes are divided considering the voltage and current waveforms. Equivalent circuit of each operation mode is illustrated and the current paths are indicated. Each mode is analyzed through the simulation. It is verified that the main switch operates at soft switching. The main switch is turned on with ZVT and turned off under near ZCS. The auxiliary switch turned on and turned off under the soft switching mode. In addition, the main diodes and auxiliary diodes turn on and off under soft switching cases. It can be clearly seen that the predicted operation principles and analysis of the proposed converter are verified with all of the simulation results. In the proposed converter, most of the drawbacks of the conventional ZVT converter are overcome both perfectly and easily. All the semiconductor devices of the converter are both turned on and off under soft switching state. There is no any additional voltage and current stresses on the main devices and the auxiliary devices.

## NOMENCLATURES

## $\Delta I_{L}$ : Input current ripple

$\Delta$ Vo: Output voltage ripple
$Z$ : Impedance of the auxiliary circuit
$D_{\text {eff }}$ : Effective duty cycle rate

## BIOGRAPHIES

Hakan Donuk was born in Diyarbakir, Turkey, 1987. He received the B.Sc. degree in Electric and Electrical Engineering from Dicle University, Diyarbakir, Turkey and is currently working on his MS thesis in Gazi University. His research areas include soft switching, active-passive snubber cells in power electronics, renewable energy.

Ires Iskender received his M.Sc. and Ph.D. degrees in Electrical and Electronic Engineering in 1990, 1996, respectively, from Middle East Technical University, Turkey. He is currently an Professor in the Department of Electrical and Electronic Engineering, Gazi University, Ankara, Turkey. His research interests include power electronic, renewable energy, fuzzy control, electrical machine, power quality

Naci Genc completed his B.S. in Electrical Education Department from Gazi University, Ankara. He received his MS from Electrical \& Electronics Engineering Department of Yuzuncu Yil University and Ph.D. Degrees from Electrical \& Electronics Engineering

Department of Gazi University in 2002 and 2010, respectively. From 1999 to 2010 he worked as a research assistant in the Electrical and Electronics Engineering Department of Yuzuncu Yil University, Middle East Technical University and Gazi University, Turkey. He is currently an Associate Professor at Yuzuncu Yil University, Van. His research interests include power electronics, electrical machines, renewable energy, solar photovoltaic energy systems and control systems.
