TABLES OF DEFLECTION AND MOMENT COEFFICIENTS FOR
THE STEADY-STATE VIBRATION OF UNIFORM BARS

by

A. S. Veletsos and N. M. Newmark

ABSTRACT

Tabulated in this report are numerical values for the following quantities: (a) coefficients of steady-state deflection for a uniform bar, fixed at one end and subjected to a harmonically varying deflection without rotation at the other end, and (b) coefficients of steady-state bending moment for a uniform bar, simply supported at both ends and subjected to a harmonically varying bending moment or deflection at one end. These quantities, together with those presented in a previous report (1)*, are intended to facilitate the determination of the steady-state response and of the natural modes of bending vibration of continuous beams and frames.

INTRODUCTION

In a previous report (1) a numerical method was presented for the calculation of the undamped natural frequencies of flexural vibration of continuous beams and frames. In Appendix C of that report, this method was also applied to the analysis of the steady-state vibration of continuous structures acted upon by harmonically varying forces, such as those resulting from rotating machinery. For a given frequency of vibration, one determines with this method the magnitude of the deflections and rotations

* Numbers in parentheses, unless otherwise identified, refer to the corresponding items in the Bibliography.

at the joints of the structure. If, in addition, one desires to determine the corresponding internal bending moments and shears, and the bending moments, shears, rotations and deflections at points between the joints, he must calculate them from the end displacements.

The steady-state bending moments and steady-state shears at the ends of a member can be calculated quite readily with the aid of the stiffness and the carry-over factors tabulated in reference (1). However, with the information available (1), (2) the deflections, rotations, shears and bending moments at points between joints cannot, in general, be obtained as readily. It is the purpose of this report to supplement the available information by providing data which can be used to facilitate the determination of the steady-state deflections and steady-state bending moments along the length of the members composing the structure.

It is proposed that the steady-state deflection at an interior point of a bar be determined by adding the deflections due to (a) the end rotations and (b) the end deflections; in each case, it is assumed that the bar is fixed at one end and subjected to the said displacement at the other end. It is further proposed that the bending moment at an interior point of a bar be determined by adding the bending moments due to (a) the end moments and (b) the end deflections, assuming, in each case, that the member is hinged at its ends.

Tabulated in this report are numerical values for the following quantities: (a) coefficients of steady-state deflection for a uniform bar, fixed at one end and subjected to a harmonically varying deflection without rotation at the other end, and (b) coefficients of steady-state

bending moment for a uniform bar, simply supported at both ends and subjected to a harmonically varying bending moment or deflection at one end. Coefficients of steady-state deflection for a uniform bar fixed at one end and subjected to a harmonically varying end rotation without deflection have already been presented in reference (1).

SIGN CONVENTION AND CHARACTERISTICS OF BARS CONSIDERED

Downward deflections are taken as positive. Bending moments are taken as positive when producing compression in the upper fibers of the bar.

The bars considered are assumed to be elastic and of uniform mass and cross section. The effects of damping, shear distortion, and rotatory inertia are neglected.

PRESENTATION OF RESULTS

Consider first a bar fixed at one end and subjected, at the other end, to a harmonically varying deflection without rotation, as shown in Fig. 1. Let the end deflection be represented by

$$\delta(t) = \delta_0 \cos \omega t , \quad (1)$$

where δ_0 is the amplitude of the deflection and ω is its circular frequency. It is desired to determine the distribution of the steady-state deflection along the length of the bar.

The steady-state deflection of the bar at a distance \bar{x} from the deflected end may conveniently be expressed as

$$y(\bar{x}, t) = C_{\delta} \delta_0 \cos \omega t , \quad (2)$$

where C_{δ} is a numerical coefficient to be discussed later.

Consider next the simply-supported bar shown in Fig. 2. Let one of its ends be subjected to a harmonically varying bending moment

$$M(t) = M_0 \cos \omega t , \quad (3)$$

where M_0 is the amplitude of the moment and ω is its circular frequency. In this case, it is desired to determine the distribution of steady-state bending moment along the length of the bar.

The steady-state bending moment in the bar at a distance \bar{x} , measured from the end where the exciting moment is applied, may be written as

$$M(\bar{x}, t) = C'_M M_0 \cos \omega t , \quad (4)$$

where, as before, the quantity C'_M is a numerical coefficient.

Consider finally that the simply-supported bar is subjected to a harmonically varying end deflection, instead of an end moment, as shown in Fig. 3. Let the end deflection be represented by Eq. (1). Then, the steady-state bending moment at a distance \bar{x} from the deflected end may be expressed as

$$M(\bar{x}, t) = C'_{\delta} \frac{EI}{L^2} \delta_0 \cos \omega t . \quad (5)$$

The coefficients C_{δ} , C'_M and C'_{δ} in Eqs. (2), (4) and (5) are dimensionless. The pertinent expression for C_{δ} has been given in Appendix B of reference (1), whereas the expressions for C'_M and C'_{δ} have been presented by Hohenemser and Prager (2). From these expressions, which for convenience are assembled in the next section, it can be seen that C_{δ} , C'_M and C'_{δ} depend (a) on the dimensionless position coordinate

\bar{x}/L , and (b) on the dimensionless parameter

$$\lambda = \sqrt[4]{\frac{m\omega^2}{EI}} L, \quad (6)$$

in which m = the mass per unit of length of the bar,

ω = the circular frequency of vibration,

E = the modulus of elasticity of the material in the bar,

I = the moment of inertia of the bar cross section about its centroidal axis, and

L = the span length of the bar.

Numerical values of C_S , C_M and C_S' , for successive twelfth points of a uniform bar, are given in Tables I, II, and III, respectively. They are presented for a range of frequencies from zero to a frequency corresponding to the third natural frequency of a fixed ended bar. All values are reported to five significant figures, but to no more than six decimal places. These quantities have been evaluated on the Electronic Digital Computer of the University of Illinois, and they are accurate to the number of figures reported.

It can readily be shown that Müller-Breslau's principle of influence lines is valid for dynamical systems undergoing steady-state forced vibration. Accordingly, the deflection coefficients given in Table I represent also ordinates of influence lines for steady-state, dynamic, fixed-end shear.

FORMULAS FOR C_{δ} , C_M' and C_{δ}'

with $\xi = \bar{x}/L$, the expressions for C_{δ} , C_M' and C_{δ}' are as follows:

$$C_{\delta} = \frac{1}{2\lambda(1 - \cosh \lambda \cos \lambda)} \left\{ \begin{array}{l} [\cosh \lambda - \cos \lambda] [\cosh (1-\xi)\lambda - \cos (1-\xi)\lambda] \\ - [\sinh \lambda + \sin \lambda] [\sinh (1-\xi)\lambda - \sin (1-\xi)\lambda] \end{array} \right\}$$

$$C_M' = \frac{\sin \lambda(1-\xi)}{2\sin \lambda} + \frac{\sinh \lambda(1-\xi)}{2\sinh \lambda}$$

$$C_{\delta}' = \lambda^2 \left[\frac{\sin \lambda(1-\xi)}{2\sin \lambda} - \frac{\sinh \lambda(1-\xi)}{2\sinh \lambda} \right]$$

ACKNOWLEDGEMENT

This investigation has been part of a research program on "Numerical and Approximate Methods of Stress Analysis" sponsored by the Mechanics Branch of the Office of Naval Research in the Structural Research Laboratory, Department of Civil Engineering, of the University of Illinois. The expressions for the quantities reported were coded for machine solution by Mr. A. J. Carlson, Jr., formerly Research Associate in Civil Engineering.

TABLE I

VALUES OF THE COEFFICIENT C_{δ}

Consider a uniform bar which is fixed at one end and is subjected to a harmonically varying deflection without rotation at the other end. For an end deflection $\delta(t) = \delta_0 \cos \omega t$, the steady-state deflection of the bar at a distance \bar{x} from the deflected end may be expressed as

$$y(\bar{x}, t) = y_{\bar{x}} \cos \omega t, \text{ where } y_{\bar{x}} = C_{\delta} \delta_0$$

Tabulated herein are values of C_{δ} for successive twelfth points of the bar as a function of the dimensionless parameter

$$\lambda = \sqrt[4]{\frac{m \omega^2}{EI}} L$$

in which m is the mass per unit of length of the bar; ω is the circular frequency of vibration; E is the modulus of elasticity of the material in the bar; I is the moment of inertia of the bar cross section about its centroidal axis; and L is the span length of the bar.

These values also represent ordinates of an influence line for steady-state fixed end shear due to a harmonically varying concentrated force.

TABLE II

VALUES OF THE COEFFICIENT C_M'

Consider a simply supported, uniform bar, subjected at one end to an exciting moment $M(t) = M_0 \cos \omega t$. Moments are considered positive when producing compression in the upper fibers of the bar.

The steady-state moment at a distance \bar{x} , measured from the end where the exciting moment is applied, is

$$M(\bar{x}, t) = M_{\bar{x}} \cos \omega t, \quad \text{where} \quad M_{\bar{x}} = C_M' M_0.$$

Tabulated herein are values of C_M' for successive twelfth points of the bar as a function of the dimensionless parameter

$$\lambda = \sqrt[4]{\frac{m \omega^2}{EI}} L$$

in which m is the mass per unit of length of the bar; ω is the circular frequency of vibration; E is the modulus of elasticity of the material in the bar; I is the moment of inertia of the bar cross section about its centroidal axis; and L is the span length of the bar.

TABLE III

VALUES OF THE COEFFICIENT C'_5

Consider a simply supported uniform bar subjected, at one end, to a deflection $\delta(t) = \delta_0 \cos \omega t$. The steady-state bending moment in the bar at a distance \bar{x} from the deflected end may then be expressed as

$$M(\bar{x}, t) = M_{\bar{x}} \cos \omega t, \quad \text{where} \quad M_{\bar{x}} = C'_5 \frac{EI}{L^2} \delta_0$$

Moments are considered positive when producing compression in the upper fibers of the bar.

Tabulated herein are values of C'_5 for successive twelfth points of the bar as a function of the dimensionless parameter

$$\lambda = \sqrt[4]{\frac{m\omega^2}{EI}} L,$$

in which m is the mass per unit of length of the bar; ω is the circular frequency of vibration; E is the modulus of elasticity of the material in the bar; I is the moment of inertia of the bar cross section about its centroidal axis; and L is the span length of the bar.
