1 **Abstract**

2 Kit/CD117 plays a crucial role in the cell-cell and cell-matrix adhesion of mammalian  
3 mast cells (MCs); however, it is unclear whether other adhesion molecule(s) perform  
4 important roles in the adhesion of MCs. In the present study, we show a novel  
5 Kit-independent adhesion mechanism of mouse cultured MCs mediated by Notch  
6 family members. On stromal cells transduced with each Notch ligand gene, Kit and its  
7 signaling become dispensable for the entire adhesion process of MCs from tethering to  
8 spreading. The Notch-mediated spreading of adherent MCs involves the activation of  
9 phosphatidylinositol 3-kinases and mitogen-activated protein kinases signaling, similar  
10 to Kit-mediated spreading. Despite the activation of the same signaling pathways, while  
11 Kit supports the adhesion and survival of MCs, Notch only supports adhesion. Thus,  
12 Notch family members are specialized adhesion molecules for MCs that effectively  
13 replace the adhesion function of Kit in order to support the interaction of MCs with the  
14 surrounding cellular microenvironments.

15

## 1 **Introduction**

2 Mast cells (MCs) are tissue-resident immune cells that constitutively express the  
3 receptor tyrosine kinase, Kit (CD117). The differentiation and survival of MCs *in vivo*  
4 depend on Kit signaling (1-3), provided by stromal cells such as fibroblasts and  
5 endothelial cells that express the Kit ligand (Kitl) (4-7).

6 In addition, the crucial roles of Kit and its signaling in the cell-cell and  
7 cell-matrix adhesion of MCs have been revealed by *in vitro* adhesion assays with  
8 cultured MCs. The adhesion of floating round-shaped cultured MCs to stromal cells  
9 begins with tethering, an anchoring response that maintains the original shape. Kit and  
10 membrane-bound Kitl function as critical cell adhesion molecules mediating the  
11 tethering of cultured MCs to fibroblasts (8-11), as shown by the impaired attachment of  
12 Kit-deficient MCs to fibroblasts (8-10). The tethering of MCs by Kit-Kitl occurs in a  
13 manner that depends on their binding, but not Kit signaling, as shown by the normal  
14 attachment response of MCs harboring mutant Kit that cannot signal (8, 10).

15 The tethering of cultured MCs is followed by the spreading (changing the cell  
16 shape) of adherent MCs, a complex response that is considered to involve integrins and  
17 cytoskeletal reorganization (15-17). Kit signaling induces the spreading of tethered MCs  
18 through not only the activation (conformational change) of integrins that enables  
19 tethered MCs to adhere to extracellular matrices (ECMs) (15-20), but also by the  
20 induction of cytoskeletal reorganization that enables MCs to deform (21-24). These  
21 processes enable MCs to spread, and make tight contact with or migrate through the  
22 surrounding cellular and ECM environments. The Kit-induced spreading of adherent  
23 MCs involves the activation of downstream signaling pathways, including  
24 phosphatidylinositol 3-kinases (PI3K) and mitogen-activated protein kinases (MAPKs)

1 (17, 18, 20-24).

2 We previously reported that Notch family members function as cell adhesion  
3 molecules for cultured mouse MCs (25-27). Notch receptors and their canonical ligands  
4 are single-pass transmembrane signaling molecules (28-32). Humans and rodents have  
5 four Notch receptors (Notch1-Notch4) and two distinct families of canonical Notch  
6 ligands: Delta-like (Dll) ligands (Dll1, Dll3, and Dll4) and Jagged (Jag) ligands (Jag1  
7 and Jag2). In MC biology, Notch signaling has been reported to regulate the  
8 differentiation (33-35), localization (36), and effector functions of MCs (37). When  
9 co-cultured with stromal cells transduced with each Notch ligand gene (Dll1, Dll4, Jag1,  
10 and Jag2), the adhesion of cultured MCs was markedly enhanced in a manner that  
11 depended on the interaction of each Notch ligand with Notch1 and Notch2 on MCs (25,  
12 26). The Notch receptor-ligand interaction strongly supported the tethering of MCs to  
13 stromal cells (25, 26), but also appeared to enhance the transitioning of tethered MCs to  
14 the spreading state. However, the mechanisms by which the spreading of MCs was  
15 induced remained unclear, and whether Kit and its signaling played a role during the  
16 Notch-mediated adhesion of MCs was unknown.

17 In the present study, in order to reveal the requirement of Kit during the  
18 Notch-mediated adhesion of MCs, we analyzed the adhesion response of Kit-deficient  
19 MCs and the effects of an antagonistic antibody against Kit on wild-type (WT) MCs on  
20 Notch ligand-transduced stromal cells. We found that a dysfunction in Kit in MCs had  
21 negligible suppressive effects on the entire adhesion process of MCs from tethering to  
22 spreading on Notch ligand-transduced stromal cells. The Kit-independent spreading of  
23 adherent MCs on Notch ligand-transduced stromal cells involved the activation of the  
24 MAPKs and PI3K pathways, similar to the Kit-dependent adhesion of WT MCs on

- 1 normal stromal cells. Our results showed the presence of a Kit-independent adhesion
- 2 mechanism of MCs mediated by Notch family members.
- 3

## 1 **Methods**

2

### 3 *Mice*

4

5 C57BL/6J mice were purchased from Japan CLEA (Tokyo, Japan). C57BL/6J-*Kit*<sup>+/W-sh</sup>  
6 mice (RBRC01888) were provided by RIKEN BRC (Ibaraki, Japan) through the  
7 National Bio-Resource Project of MEXT, Japan, and were bred to obtain  
8 C57BL/6J-*Kit*<sup>+/+</sup> and -*Kit*<sup>W-sh/W-sh</sup> mice. Mice were maintained in a specific  
9 pathogen-free facility in Tottori University. Experiments were approved by and  
10 performed in accordance with the guidelines of the Animal Care and Use Committee of  
11 Tottori University.

12

### 13 *Bone marrow-derived cultured MCs*

14

15 Cells from femora were cultured in minimum essential medium alpha (MEM $\alpha$ ;  
16 Gibco-BRL, Grand Island, NY) supplemented with 10% fetal bovine serum (FBS, JRH  
17 Biosciences, Lenexa, KS), antibiotics (penicillin and streptomycin, Meiji Seika, Tokyo,  
18 Japan), and 50 U/mL culture supernatant of Chinese hamster ovary cells producing  
19 recombinant mouse interleukin (IL)-3 (a gift from Dr. Sudo, Toray Industries, Inc.,  
20 Kanagawa, Japan) in a humidified atmosphere with 5% CO<sub>2</sub> at 37°C. Non-adherent  
21 cells were placed into fresh media every 5-7 days. After more than 8 weeks, more than  
22 97% of cells were MCs, as judged by the surface expression of Kit and Fc $\epsilon$ RI $\alpha$  with  
23 flow cytometry (25, 26). In Figure 1A, MCs obtained from C57BL/6J mice (Japan  
24 CLEA) were used. In other experiments, MCs from age- and sex-matched pairs of

1 C57BL/6J-*Kit*<sup>+/+</sup> and -*Kit*<sup>W-sh/W-sh</sup> mice (RIKEN BRC) were used.

2

### 3 *Stromal Cells*

4

5 OP9 stromal cell lines transduced with the mouse Dll1, Dll3, Dll4, Jag1, or Jag2 gene  
6 (OP9-Dll1, -Dll3, -Dll4, -Jag1 or -Jag2) and control OP9-Ret10 cells (OP9-Ctrl) were as  
7 described previously (38). All OP9 cells expressed the green fluorescent protein (GFP).  
8 They were cultured with MEM $\alpha$  supplemented with 20% FBS and antibiotics.

9

### 10 *Antibodies*

11

12 The following monoclonal antibodies (mAbs) were used in flow cytometry:  
13 FITC-conjugated anti-mouse Kit (ACK2, Tonbo Biosciences, San Diego, CA) (39),  
14 PE-conjugated anti-mouse Fc $\epsilon$ RI $\alpha$  (MAR-1), and CD49b (DX5) (eBioscience, San  
15 Diego, CA).

16 Unlabeled ACK2, anti-mouse IL-7R $\alpha$  (A7R34), and anti-mouse Gr-1  
17 (RB6-8C5) mAb dissolved in PBS were used in cell cultures (all made in-house).  
18 Purified sheep anti-mouse Notch1 (AF5267) or Notch2 (AF5196) polyclonal Abs  
19 (pAbs) and sheep control IgG (5-001-A) were purchased from R&D Systems  
20 (Minneapolis, MN).

21

### 22 *Reagents*

23

24 Sodium azide (NaN<sub>3</sub>), dimethylsulfoxide (DMSO), SB203580, SP600125, and

1 PD98059 (Wako Pure Chemical Industries, Osaka, Japan), LY294002 (Merck Millipore,  
2 Darmstadt, Germany), *N*-[*N*-(3,5-difluorophenacetyl)-L-alanyl]-S-phenylglycine t-butyl  
3 ester (DAPT) (Peptide Institute, Osaka, Japan), and cytochalasin D (Sigma-Aldrich, St  
4 Louis, MO) were used.

5

#### 6 *Reverse transcriptase-polymerase chain reaction (RT-PCR)*

7

8 A RT-PCR analysis was performed as previously described (26). Briefly, synthesized  
9 cDNA (equivalent to 25 ng total RNA) was amplified using rTaq DNA polymerase and  
10 TaKaRa PCR Thermal Cycler Dice<sup>®</sup> Gradient (Takara, Shiga, Japan). Primers were as  
11 described: *Kit* (40), *Fcer1a* (41), and *Kitl* (25).

12

#### 13 *Adhesion assay*

14

15 OP9 stromal cells ( $1.6 \times 10^4$  for 48-well plates (for Figure 1A) and  $5.0 \times 10^3$  for 96-well  
16 plates (for other experiments)) were seeded in the wells of 48- or 96-well flat-bottomed  
17 culture plates (Corning) and cultured for 2 days in order to prepare confluent  
18 monolayers. After washing OP9 cells once with phosphate-buffered saline (PBS), MCs  
19 suspended in MEM $\alpha$  with 10% FBS were seeded onto the wells ( $1.5 \times 10^5$  in 100  $\mu$ L for  
20 48-well plates and  $5.0 \times 10^4$  in 50  $\mu$ L for 96-well plates) with or without reagents, and  
21 incubated at 37°C for 60 min. In adhesion assays with inhibitors (SB203580, SP600125,  
22 PD98059 LY294002, and DAPT), MCs were pre-treated with the inhibitors at room  
23 temperature for 10 - 60 min, and then seeded onto OP9 cells with inhibitors. The culture  
24 supernatant was recovered after agitation (low speed, scale 5) for 30 sec with a

1 MicroMixer E-36 (Taitec corporation, Saitama, Japan), and non-adherent MCs in the  
2 supernatants were counted with hemocytometers. The percentages and numbers of  
3 adherent MCs relative to those initially added were calculated.

4 In the assay with fixed stromal cells, confluent monolayers of each OP9 cell  
5 were fixed with 2% paraformaldehyde (PFA, Wako) at room temperature for 5 min.  
6 After washing wells three times with PBS, the adhesion assay was performed.

7 In the evaluation of the adhesion states of MCs, photomicrographs  
8 (magnification:  $\times 200$ ) of each well (avoiding the center of the wells at which adherent  
9 MCs were very dense) were taken immediately after the removal of the supernatant. The  
10 numbers of adherent MCs in each adhesion state in a chosen area  
11 ( $1000 \times 1000 \sim 1200 \times 1200$  pixels) in a well were counted, and the numbers of adherent  
12 MCs in each state were calculated.

13

#### 14 *Survival assay*

15

16 OP9 stromal cells ( $3 \times 10^4$  for 24-well plates (for Figure 6B and 6C) and  $1.5 \times 10^4$  for  
17 48-well plates (for other experiments)) were seeded on the 0.1% type A gelatin  
18 (Sigma-Aldrich)-coated wells of 24-well or 48-well flat-bottomed culture plates  
19 (Corning). The next day, MCs ( $1.5 \times 10^5$  in 500  $\mu\text{L}$  for 24-well plates and  $7.5 \times 10^4$  in 200  
20  $\mu\text{L}$  for 48-well plates) suspended in MEM $\alpha$  with 10% FBS were seeded on the  
21 sub-confluent OP9 monolayer with or without reagents, and were cultured at 37°C for 7  
22 days. On day 4, 1 $\times$  volume of fresh media without or with inhibitors (1 $\times$  concentration)  
23 were added. On day 7, all cells in a well were recovered by trypsinization, stained with  
24 propidium iodide (PI, Sigma-Aldrich) to exclude dead cells, and suspended in the same

1 volume of buffer. Cells were analyzed with the flow cytometer EPICS XL (Coulter, Palo  
2 Alto, CA) under the same flow rate for 60 sec. GFP-positive cells (OP9 cells) were  
3 excluded and live MCs (PI<sup>-</sup>GFP<sup>-</sup>) were counted using WinMDI ver 2.9 software (Purdue  
4 University, West Lafayette, IN). The percentages of live MCs relative to those initially  
5 added, which were analyzed with the same methods on day 0, were calculated.

6

### 7 *Flow cytometry*

8

9 Hank's solution (Nissui Pharmaceutical, Tokyo, Japan) containing 2.5% heat-inactivated  
10 FBS and 0.02% NaN<sub>3</sub> was used as staining buffer. Cells were initially incubated with  
11 33% rabbit serum (Gibco) with anti-CD16/32 (2.4G2, Tonbo Biosciences) for blocking,  
12 and then stained with fluorescein-labeled mAbs and PI. Regarding the detection of  
13 Notch receptors in Figure 1D, cells were stained with fluorescein-labeled mAbs and  
14 sheep control, anti-mouse Notch1, or anti-mouse Notch2 pAbs (R&D Systems), and  
15 then with rabbit anti-sheep IgG-biotin (Vector Laboratories) and streptavidin-PE  
16 (SouthernBiotech). Cells were analyzed with EPICS XL and WinMDI software.

17

### 18 *Statistical analysis*

19

20 Each experiment was repeated more than twice, with similar results being obtained each  
21 time, and representative results were shown unless otherwise indicated. Statistical  
22 analyses were performed in Microsoft Excel (for Welch's *t*-test) and IBM SPSS  
23 Statistics version 25 (for a one-way ANOVA with post-hoc tests). The significance of  
24 differences was established at  $p < 0.05$ .

25

## 1 **Results**

2

3 *Kit* was dispensable for the adhesion of MCs to Notch ligand-transduced stromal cells

4

5 In order to examine the role of Kit during Notch-mediated MC adhesion, WT cultured  
6 MCs were incubated on a confluent monolayer of OP9 stromal cells transduced with  
7 each Notch ligand gene (OP9-Dll1, -Dll4, -Jag1, and -Jag2) (26, 38), with or without  
8 ACK2, an antagonistic mAb against mouse Kit. In the presence of a control mAb, the  
9 adhesion of MCs was more strongly promoted on OP9-Dll1, -Dll4, -Jag1, or -Jag2 than  
10 the responses on OP9-Ctrl (Figure 1A, open circles). The addition of ACK2  
11 significantly inhibited the adhesion of MCs to OP9-Ctrl cells, but had a negligible effect  
12 on adhesion to OP9 cells transduced with Notch ligands (Figure 1A).

13 We then assessed cultured MCs obtained from C57BL/6-*Kit*<sup>+/+</sup> and -*Kit*<sup>W-sh/W-sh</sup>  
14 mice (hereafter MCs-*Kit*<sup>+/+</sup> and -*Kit*<sup>W-sh/W-sh</sup>) (Supplemental Figure 1). *W<sup>sh</sup>* is an  
15 inversion mutation in the transcriptional regulatory elements upstream of the *Kit*  
16 transcription start site (37). Therefore, MCs-*Kit*<sup>W-sh/W-sh</sup> failed to express the *Kit* (9), but  
17 not *Fcer1a* transcript (Figure 1B and supplemental Figure 1). The adhesion of  
18 MCs-*Kit*<sup>W-sh/W-sh</sup> to OP9-Ctrl cells at 60 min of the adhesion assay was significantly  
19 weaker than that of MCs-*Kit*<sup>+/+</sup> (Figure 1C). In contrast, the promoted adhesion of MCs  
20 to OP9-Dll1, -Dll4, -Jag1, and -Jag2 was not influenced by the insufficiency of Kit  
21 expression (Figure 1C). MCs-*Kit*<sup>+/+</sup> and -*Kit*<sup>W-sh/W-sh</sup> were both immature (Supplemental  
22 Figure 2) and expressed Notch1 and Notch2 on their surfaces (Figure 1D). Mature  
23 peritoneal MCs from C57BL/6 mice also expressed Notch1 and Notch2 (Figure 1D and  
24 Supplemental Figure 2), suggesting that the expression of Notch receptors is maintained

1 throughout the maturation of MCs. MCs-*Kit*<sup>W-sh/W-sh</sup> did not express *Kit* mRNA after a  
2 60-min co-culture with each OP9 transductant (Figure 1E) and every OP9 transductant  
3 expressed *Kitl*, but not *Kit* or *Fcer1a* mRNA (Figure 1F and Supplemental Figure 3).

4           These results showed that the lack of the Kit-Kitl interaction did not affect the  
5 adhesion of MCs to Notch ligand-transduced stromal cells.

6  
7 *Spreading of adherent MCs on Notch ligand-transduced stromal cells was affected less*  
8 *by the insufficiency of Kit in MCs*

9  
10 Kit signaling induces cytoskeletal reorganization, leading to changes in the cell  
11 morphology of adherent MCs (21-23). In our adhesion assay, while some adherent MCs  
12 maintained their original morphology (spherical and refractile), some adherent MCs  
13 spread on stromal cells with deformed shapes and appeared dark under phase-contrast  
14 microscopy (Figure 2A). In cultures with the inhibition of cellular metabolism by NaN<sub>3</sub>  
15 (a mitochondrial F-ATPase inhibitor) (43) or on ice, and in the presence of cytochalasin  
16 D (an actin polymerization inhibitor), deformed MCs were not observed and most of the  
17 adherent MCs maintained their original morphology (Figure 2B). Therefore, deformed  
18 and dark-looking adherent MCs represented an advanced stage of cell adhesion  
19 accompanied by cytoskeletal reorganization.

20           Using photomicrographs of adherent MCs after the removal of floating cells,  
21 we assessed the numbers of adherent MCs in each adhesion state, i.e., refractile ones as  
22 in tethering, dark ones as in spreading, and intermediate ones as in a transitional stage  
23 (Figure 2A). In the adhesion assay for MCs-*Kit*<sup>+/+</sup> on OP9-Ctrl cells, the ratio and  
24 number of spreading MCs were gradually increased and maximized at 60-120 min

1 (Figure 2C and 2D). In contrast, MCs-*Kit<sup>W-sh/W-sh</sup>* showed an impaired transition from  
2 the tethering to spreading state (Figure 2C and 2D), demonstrating the importance of  
3 Kit signaling in this process. The kinetics of the adhesion states of MCs-*Kit<sup>+/+</sup>* on  
4 OP9-Dll1, -Dll4, -Jag1, and -Jag2 were similar to that on OP9-Ctrl, except that the  
5 numbers of transitioning plus spreading MCs were higher (Figure 2E).

6 We compared the numbers of adherent MCs in each state at 60 min between  
7 MCs-*Kit<sup>+/+</sup>* and MCs-*Kit<sup>W-sh/W-sh</sup>* (Figure 3A and 3B). MCs-*Kit<sup>+/+</sup>* showed higher cell  
8 numbers in the transitioning plus spreading states on OP9-Dll1, -Dll4, and -Jag1 than  
9 those on OP9-Ctrl (Figure 3B, each left bars). The numbers of spreading MCs-*Kit<sup>+/+</sup>* on  
10 OP9-Dll4 and -Jag1 were significantly higher than that on OP9-Ctrl cells in some (but  
11 not all) experiments. In contrast to the response on OP9-Ctrl cells, the lack of Kit in  
12 MCs-*Kit<sup>W-sh/W-sh</sup>* only had a small inhibitory or no effect on their transition from the  
13 tethering to spreading states on Notch ligand-transduced OP9 cells (Figure 3B).  
14 Moreover, the treatment with ACK2 during the adhesion assay did not markedly affect  
15 the spreading response of MCs-*Kit<sup>+/+</sup>* on Notch ligand-transduced OP9 cells (Figure  
16 3C).

17 These results indicate that the spreading of adherent MCs on OP9-Ctrl cells  
18 required Kit signaling, whereas that on Notch ligand-transduced stromal cells mostly  
19 occurred in a Kit-independent manner.

20

21 *Spreading of MCs-Kit<sup>W-sh/W-sh</sup> on Notch ligand-transduced stromal cells occurred in a*  
22 *manner depending on the Notch receptor-ligand interaction, but not canonical Notch*  
23 *signaling*

24

1 We hypothesized that Notch receptors on MCs functioned not only as cell adhesion  
2 molecules mediating the tethering of MCs (25, 26), but also induced the subsequent  
3 spreading of adherent MCs via Notch signaling. In canonical signaling, Notch  
4 receptor-ligand binding between neighboring cells ultimately induces the proteolytic  
5 cleavage of the receptor by the  $\gamma$ -secretase complex. This permits the Notch intracellular  
6 domain to translocate into the nucleus, in which it induces the transcription of Notch  
7 target genes (28-32). MCs mainly express Notch2 and, to a lesser extent, Notch1, both  
8 of which cooperatively function in the Notch-mediated adhesion of MCs (26). The  
9 treatment with anti-Notch1 plus anti-Notch2 pAbs during the adhesion assay for  
10 MCs-*Kit*<sup>W-sh/W-sh</sup> significantly reduced the numbers of adherent MCs in each adhesion  
11 state on each Notch ligand-transduced OP9 cell (Figure 4A). The treatment of these  
12 pAbs did not affect the adhesion states of MCs-*Kit*<sup>W-sh/W-sh</sup> on OP9-Ctrl cells. Thus, the  
13 initiation of the entire adhesion process of MCs-*Kit*<sup>W-sh/W-sh</sup> depended on the Notch  
14 receptor-ligand interactions on Notch ligand-transduced OP9 cells.

15 We then tested whether the treatment with the canonical Notch signaling  
16 inhibitor, DAPT ( $\gamma$ -secretase inhibitor) inhibited the spreading of adherent MCs. The  
17 treatment with 50  $\mu$ M DAPT had no effect on the adhesion states of MCs-*Kit*<sup>W-sh/W-sh</sup> on  
18 each OP9 cell (Figure 4B). The spreading of MCs-*Kit*<sup>+/+</sup> on each OP9 cell in the  
19 presence of ACK2 was also not suppressed by the additional treatment with DAPT  
20 (Figure 4C). We previously confirmed that the treatment of 10  $\mu$ M DAPT was sufficient  
21 to reverse the activation of transcription of Notch target genes (*Hes1* and *Hey1*) in WT  
22 MCs cultured on OP9-Dll1 (26).

23 These results indicated that the spreading of adherent MCs-*Kit*<sup>W-sh/W-sh</sup> in  
24 Notch-mediated cell adhesion was dependent on the Notch receptor-ligand interaction,

1 but independent of canonical Notch signaling mediated by  $\gamma$ -secretase activity.

2  
3 *Kit-independent spreading of adherent MCs-Kit<sup>W-sh/W-sh</sup> on Notch ligand-transduced*  
4 *stromal cells involved the activation of MAPKs and PI3K pathways*

5  
6 Kit signaling activates PI3K and three MAPKs pathways: p38 MAPKs, extracellular  
7 signal-regulated kinases (ERKs), and c-Jun amino-terminal kinases (JNKs) (44-47).

8 These signaling pathways mediate the Kit-induced cytoskeletal reorganization of  
9 adherent MCs (21-23). Consistent with these findings, the numbers of the Kit-dependent  
10 spreading of adherent MCs-Kit<sup>+/+</sup> on OP9-Ctrl cells were significantly reduced, and  
11 tethering was increased by the treatment with inhibitors for p38 (SB203580), JNKs  
12 (SP600125), ERK1/2 (PD98059), and PI3K (LY294002) (Figure 5A).

13 Treatments with these inhibitors also significantly impaired the spreading, and  
14 increased the tethering of MCs-Kit<sup>W-sh/W-sh</sup> on OP9-Dll4 cells (Figure 5B and 5D) and  
15 other Notch ligand-transduced OP9 cells (Supplemental Figure 4). In order to exclude  
16 the effects of these inhibitors on stromal cells, we performed the adhesion assay on 2%  
17 PFA-fixed OP9-Dll4 cells. The spreading of adherent MCs-Kit<sup>W-sh/W-sh</sup> was also  
18 significantly inhibited and most of the adherent MCs were tethering by the treatment  
19 with these inhibitors (Figure 5C and 5D).

20 These results suggested that on Notch ligand-transduced stromal cells, MAPKs  
21 (p38, JNK and ERK) and PI3K pathways were all activated, even in Kit-deficient MCs,  
22 directing the effective spreading of adherent MCs.

23  
24 *Notch receptor-ligand interactions did not support the survival of MCs-Kit<sup>W-sh/W-sh</sup>*

1

2 On fibroblasts expressing Kitl, while WT MCs survive over the long term, MCs lacking  
3 functional Kit cannot survive and disappear from the culture (8, 9). Kit signaling  
4 prevents the apoptosis of cultured MCs in a manner depending on the activation of the  
5 PI3K and ERKs pathways (48, 49). Since the PI3K and MAPKs pathways in MCs were  
6 activated in a Kit-independent manner on Notch ligand-transduced OP9 cells, we  
7 investigated whether Notch ligand-transduced OP9 cells support the survival of  
8 Kit-deficient MCs.

9       After culturing MCs-*Kit*<sup>+/+</sup> or -*Kit*<sup>W-sh/W-sh</sup> on each OP9 transductant for 7 days,  
10 the number of live MCs-*Kit*<sup>W-sh/W-sh</sup> was significantly lower than that of MCs-*Kit*<sup>+/+</sup> on  
11 every OP9 transductant (Figure 6A and Supplemental Figure 5A). Any improvement in  
12 the survival of MCs-*Kit*<sup>W-sh/W-sh</sup> on every Notch ligand-transduced OP9 cell was not  
13 observed from their response on OP9-Ctrl (Figure 6A). Without OP9 stromal cells,  
14 neither MCs-*Kit*<sup>+/+</sup> nor -*Kit*<sup>W-sh/W-sh</sup> survived (Figure 6A, OP9(-)). The survival responses  
15 of MCs-*Kit*<sup>+/+</sup> on OP9-Dll4 and -Jag2 were slightly weaker than those on OP9-Ctrl  
16 (Figure 6A), and were improved in the presence of DAPT in 3 out of 3 or 1 out of 3  
17 experiments, respectively (Supplemental Figure 5B), suggesting that Notch signaling  
18 exerts negative effects on the survival of MCs. Histocytochemistry showed that granule  
19 contents in MCs-*Kit*<sup>+/+</sup> cultured on every OP9 transductant remained in the immature  
20 state (Supplemental Figure 6). The survival of MCs-*Kit*<sup>+/+</sup> on OP9-Ctrl depended on Kit  
21 signaling because the treatment with ACK2 reduced their survival to the level of  
22 MCs-*Kit*<sup>W-sh/W-sh</sup> (Figure 6B). In addition, the survival of MCs-*Kit*<sup>+/+</sup> on OP9-Ctrl was  
23 impaired by the inhibition of PI3K (LY294002) and, to a lesser extent, p38 (SB203580)  
24 and ERK1/2 (PD98059) (Figure 6C), showing the involvement of these signaling

1 pathways in the Kit-dependent survival of MCs. The effects of the JNK inhibitor  
2 (SP600125) were unclear because of its toxicity against stromal cells in this long-term  
3 culture (data not shown).

4         These results suggested that although Notch ligand-transduced stromal cells  
5 effectively supported the entire adhesion process of Kit-deficient MCs from tethering to  
6 spreading, with the latter process involving the activation of the PI3K and MAPKs  
7 pathway, they were unable to support the survival of MCs-*Kit<sup>W-sh/W-sh</sup>*. Thus, Notch  
8 family members were specialized molecules for the mediation of the cell adhesion of  
9 MCs, while Kit supported the survival and adhesion of MCs (Figure 7).

10

## 1 **Discussion**

2

3 We herein demonstrated the existence of a Kit-independent adhesion mechanism for  
4 mammalian MCs mediated by Notch family members (Figure 7). On Notch  
5 ligand-transduced stromal cells, not only was the entire adhesion process of cultured  
6 MCs from tethering to spreading effectively induced in a manner depending on the  
7 Notch receptor-ligand interaction, but Kit became dispensable to this process. Thus, the  
8 Notch-mediated adhesion of MCs is a novel mode of MC interaction with the  
9 surrounding microenvironments.

10 A small number of Kit-deficient MCs still adhered to OP9-Ctrl cells. Although  
11 OP9-Ctrl cells weakly expressed endogenous Jag1 on their surface (26), it did not  
12 contribute to the adhesion of MCs (ref. 26 and Figure 4A), suggesting that other  
13 adhesion molecules, such as ICAM1 and VCAM1, expressed by OP9 cells (25) are  
14 involved in this process. This result also indicates that Notch ligands require a certain  
15 level of surface expression to induce MC adhesion. Our results suggested that when  
16 expression exceeds a certain level, the functions of the Notch-mediated and  
17 Kit-mediated adhesion pathways become redundant.

18 The Notch-mediated spreading of adherent MCs involved the activation of  
19 PI3K and MAPKs (p38, JNK, ERK), similar to Kit-mediated spreading. However, it is  
20 unclear how these pathways are activated in Kit-deficient MCs during Notch-mediated  
21 adhesion. Since  $\gamma$ -secretase activity, which is essential for canonical Notch signaling,  
22 was dispensable for the induction of spreading, the  $\gamma$ -secretase-independent  
23 non-canonical Notch signaling pathway may be involved (50-52). Previous studies  
24 suggested the direct activation of the PI3K pathway by non-canonical Notch signaling

1 (53-55). In contrast, although Notch signaling has been shown to indirectly regulate  
2 MAPKs signaling activated by other cell surface receptors (56-66), there does not  
3 appear to be any evidence of direct MAPKs activation by non-canonical Notch  
4 signaling. Therefore, one possible mechanism for Notch-mediated spreading is that  
5 non-canonical Notch signaling directly activates PI3K and indirectly enhances MAPKs  
6 pathways in tethered MCs, leading to cytoskeletal reorganization for deforming (Figure  
7 7).

8 Notch ligand-rich environments did not support the survival of Kit-deficient  
9 MCs despite their capacities to activate the MAPKs and PI3K pathways in adherent  
10 MCs. Kit-mediated MC survival involves the down-regulation of pro-apoptotic BCL-2  
11 family members (Bim and Puma) by a series of reactions starting from activated PI3K  
12 and ERK (48, 49). Thus, the Notch-mediated activation of these signaling pathways  
13 may not lead to the down-regulation of Bim or Puma. Although it currently remains  
14 unclear why this qualitative difference between the Kit- and Notch-mediated activation  
15 of PI3K and ERK occurs, Notch family members appear to be specialized molecules  
16 that induce cell adhesion, while Kit supports the adhesion and survival of MCs.

17 The physiological conditions under which Notch-mediated MC adhesion is  
18 operating remain unknown; however, this adhesion will enable MCs to maintain or to  
19 form cell-cell and cell-ECM adhesion with cells not expressing Kitl, but expressing  
20 Notch ligands, or when Kit-mediated adhesion becomes dysfunctional. There are some  
21 inhibitory mechanisms of Kit-mediated MC responses. The binding of Kitl induces the  
22 internalization of surface Kit on MCs (67, 68) and the activation of MCs induces the  
23 shedding of the Kit ectodomain through the activation of proteases (67-69), both of  
24 which result in the impaired adhesion of MCs to fibroblasts (68). Moreover, blood

1 plasma contains a higher level of the soluble Kit ectodomain than soluble Kitl (70), and  
2 soluble Kit inhibits Kitl bioactivity by acting as a decoy (71). One possible condition  
3 under which Notch-mediated adhesion functions is chronic inflammation, in which  
4 Notch ligands are up-regulated in stromal cells (72-76) and MCs frequently accumulate  
5 (77). Therefore, the activation of tissue MCs and increased vascular permeability may  
6 lead to impaired Kit-mediated MC adhesion. Notch-mediated adhesion may provide an  
7 advantage to MCs harboring reduced surface Kit for their interactions with and  
8 migration through the surrounding cellular environments.

9 In mice, the niche retention of hematopoietic stem cells (HSCs) in bone  
10 marrow was recently suggested to involve Notch-mediated cell adhesion (78, 79). Since  
11 HSCs express Kit and Notch receptors as MCs, further studies are warranted in order to  
12 examine the relationship between these two receptors in niche retention based on our  
13 results. Moreover, since the expression of Notch receptors is considered to be  
14 maintained throughout the differentiation of diverse immune cell lineages (28, 30), the  
15 role of Notch-mediated cell adhesion in various Notch-dependent responses throughout  
16 life needs to be examined.

## 1 Figure legends

2  
3 **Figure 1.** Adhesion of MCs to Notch ligand-transduced OP9 stromal cells was not  
4 inhibited by the insufficiency of Kit in MCs. (A) WT MCs were cultured on each OP9  
5 stromal cell with 5  $\mu\text{g/ml}$  of anti-IL-7R $\alpha$  mAb (Ctrl mAb) or anti-Kit mAb (ACK2).  
6 The percentages of adherent MCs at each incubation time (5, 15, 30, 60, and 120 min)  
7 were shown. Data are the mean  $\pm$  S.E. of triplicate cultures ( $*p < 0.05$  between Ctrl  
8 mAb and anti-Kit mAb at each time point, 2-tailed Welch's *t*-test). (B) Surface  
9 expression of Kit and Fc $\epsilon$ RI $\alpha$  on MCs-*Kit*<sup>+/+</sup> and -*Kit*<sup>W-sh/W-sh</sup>. (C) Percentages of  
10 adherent MCs-*Kit*<sup>+/+</sup> and -*Kit*<sup>W-sh/W-sh</sup> on each OP9 stromal cell at 60 min of the adhesion  
11 assay were shown (mean  $\pm$  S.E. of triplicate cultures.  $*p < 0.05$ , 2-tailed Welch's *t*-test).  
12 (D) Surface expression of Notch1 and Notch2 on MCs-*Kit*<sup>+/+</sup> and -*Kit*<sup>W-sh/W-sh</sup>, and Kit<sup>+</sup>  
13 peritoneal MCs (See Supplemental Figure 2). (E) The expression of *Kit* and *Fcer1a* in  
14 the mixed lysates of adherent MCs-*Kit*<sup>+/+</sup> or -*Kit*<sup>W-sh/W-sh</sup> and each OP9 stromal cell after  
15 60 min of the adhesion assay was analyzed by RT-PCR. RT-PCR with total RNAs from  
16 each MC alone before the adhesion assay was designated as 'Pre'. (F) The expression of  
17 *Kit*, *Fcer1a*, and *Kitl* in each OP9 stromal cell was analyzed by RT-PCR. (E, F) Original  
18 gel sources and negative controls are in Supplemental Figure 1.

19  
20 **Figure 2.** Temporal changes in adhesion states of MCs on OP9 cells. (A) A  
21 representative photomicrograph of adherent MCs-*Kit*<sup>+/+</sup> on OP9-Dll4 cells after the  
22 removal of non-adherent MCs at 60 min of the adhesion assay. Scale bar; 50  $\mu\text{m}$ . (B)  
23 (Left panels) Adhesion assay (60 min) for MCs-*Kit*<sup>+/+</sup> on OP9-Dll4 cells with the  
24 F-ATPase inhibitor NaN<sub>3</sub> (50 mM) or its solvent PBS (0.83% vol/vol) at 37°C or on ice.  
25 (Right panels) Adhesion assay (60 min) for MCs-*Kit*<sup>+/+</sup> on 2% PFA-fixed OP9-Dll4  
26 cells with the actin polymerization inhibitor cytochalasin D (5  $\mu\text{M}$ ) or its solvent DMSO  
27 (0.05% vol/vol). Photomicrographs of adherent MCs were shown. Arrowhead:  
28 spreading MCs. (C, D) Adhesion assays for MCs-*Kit*<sup>+/+</sup> and MC-*Kit*<sup>W-sh/W-sh</sup> on OP9-Ctrl  
29 cells with various incubation times. (C) The ratios and (D) numbers of adherent MCs in  
30 each adhesion state in a well were shown. (E) Adhesion assays for MCs-*Kit*<sup>+/+</sup> with  
31 various incubation times on each OP9 transductant. Dotted lines indicate the total  
32 number of MCs plated in each well.

33  
34 **Figure 3.** Spreading of adherent MCs on Notch ligand-transduced OP9 stromal cells  
35 was affected less by the insufficiency of Kit in MCs. (A and B) Adhesion assays (60  
36 min) for MCs-*Kit*<sup>+/+</sup> and MCs-*Kit*<sup>W-sh/W-sh</sup> on each OP9 cell. (A) Representative

1 photomicrographs of adherent MCs. Scale bar; 50  $\mu$ m. Arrowhead: spreading MCs. (B)  
2 The numbers of adherent MCs in each state were shown. (C) Adhesion assays (60 min)  
3 for MCs-*Kit*<sup>+/+</sup> on each OP9 cell with a control mAb (A7R34) or anti-Kit mAb (ACK2)  
4 (10  $\mu$ g/ml each). (B and C) Data are the mean  $\pm$  S.E. of triplicate cultures. Dotted lines  
5 indicate the total number of MCs plated on each well. Asterisks denote significant  
6 differences in each adhesion state between (B) MCs-*Kit*<sup>+/+</sup> and MCs-*Kit*<sup>W-sh/W-sh</sup> or (C)  
7 the control mAb and ACK2 ( $p < 0.05$ , 2-tailed Welch's *t*-test).

8  
9 **Figure 4.** Spreading of adherent MCs-*Kit*<sup>W-sh/W-sh</sup> on Notch ligand-transduced OP9  
10 stromal cells was dependent on the Notch receptor-ligand interaction, but independent  
11 of  $\gamma$ -secretase-mediated Notch signaling. (A) Adhesion assays (60 min) for  
12 MCs-*Kit*<sup>W-sh/W-sh</sup> on each OP9 cell with control pAb (20  $\mu$ g/ml) or anti-Notch1 pAb plus  
13 anti-Notch2 pAb (10  $\mu$ g/ml each). Cultures contained 76.9  $\mu$ M NaN<sub>3</sub>, which had no  
14 effect on the adhesion of MCs. (B) MCs-*Kit*<sup>W-sh/W-sh</sup> were pretreated with the  $\gamma$ -secretase  
15 inhibitor DAPT (50  $\mu$ M) or its solvent DMSO (0.5% vol/vol) for 30 min, and the  
16 adhesion assay (60 min) was performed with the reagents. (C) MCs-*Kit*<sup>+/+</sup> were  
17 pretreated with an anti-Kit mAb (ACK2, 10  $\mu$ g/ml) plus DAPT (30  $\mu$ M) or DMSO  
18 (0.3% vol/vol) for 10 min, and the adhesion assay (60 min) was performed with the  
19 reagents. Data are the mean  $\pm$  S.E. of triplicate cultures. Asterisks denote the  
20 significantly different responses of each adhesion state from control treatments ( $p <$   
21 0.05, 2-tailed Welch's *t*-test).

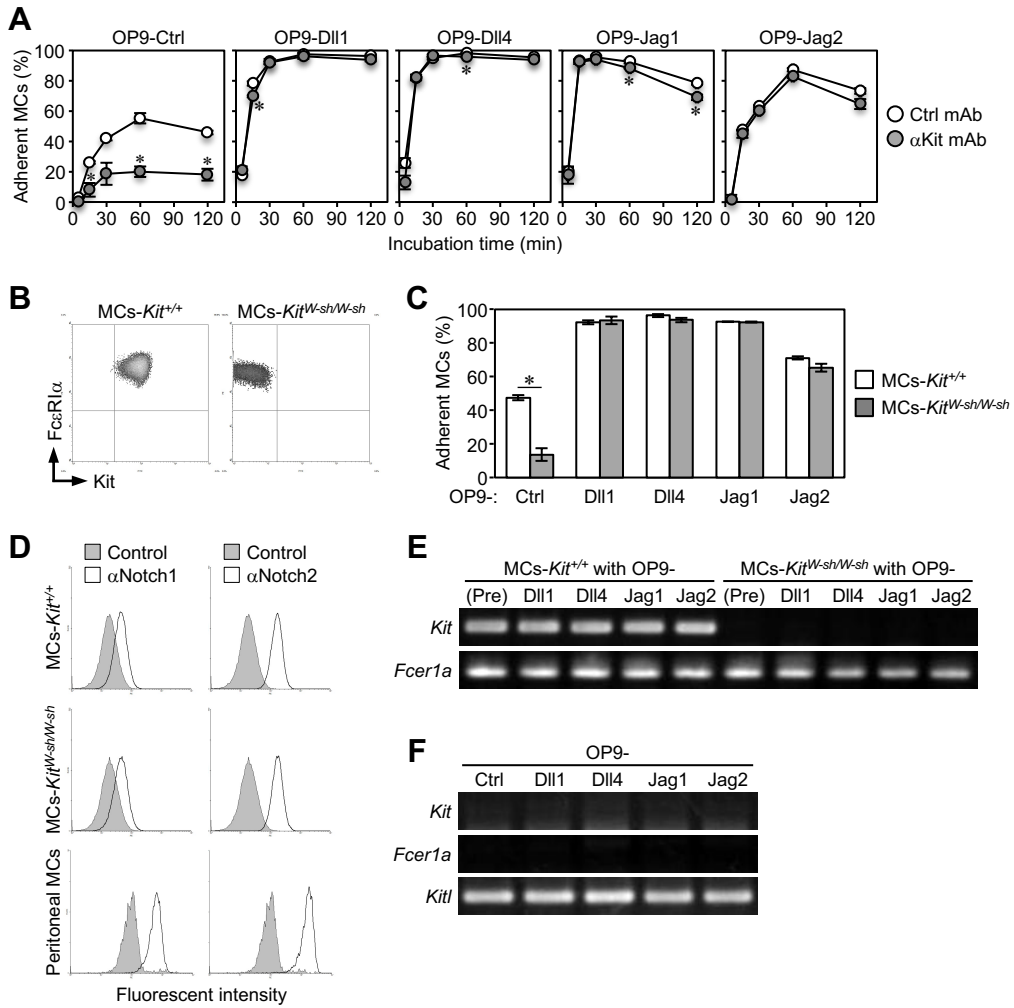

22  
23 **Figure 5.** Kit- and Notch-dependent spreading of adherent MCs both involved MAPKs  
24 and PI3K signaling in MCs. (A-D) MCs-*Kit*<sup>+/+</sup> or MCs-*Kit*<sup>W-sh/W-sh</sup> were pretreated with  
25 SB203580 (p38 inhibitor, 50  $\mu$ M), SP600125 (JNK inhibitor, 50  $\mu$ M), PD98059  
26 (MEK1/2 inhibitor, 50  $\mu$ M), LY294002 (PI3K inhibitor, 20  $\mu$ M), or the solvent DMSO  
27 (0.25% vol/vol) for 60 min, and adhesion assays (60 min) were performed with the  
28 reagents on the indicated OP9 stromal cells. Data are the mean  $\pm$  S.E. of triplicate  
29 cultures. Asterisks denote the significantly different responses of each adhesion state  
30 from control treatments ( $p < 0.05$ , 1-tailed Welch's *t*-test). (D) Representative  
31 photomicrographs of adherent MC-*Kit*<sup>W-sh/W-sh</sup> under the indicated conditions in (B) and  
32 (C). Scale bar; 50  $\mu$ m. Arrowhead; spreading MCs.

33  
34 **Figure 6.** The Notch receptor-ligand interaction did not support the survival of  
35 MCs-*Kit*<sup>W-sh/W-sh</sup>. MCs-*Kit*<sup>+/+</sup> and MCs-*Kit*<sup>W-sh/W-sh</sup> were cultured on each OP9 stromal  
36 cell for 7 days with the indicated reagents. Percent control responses of live MCs to day

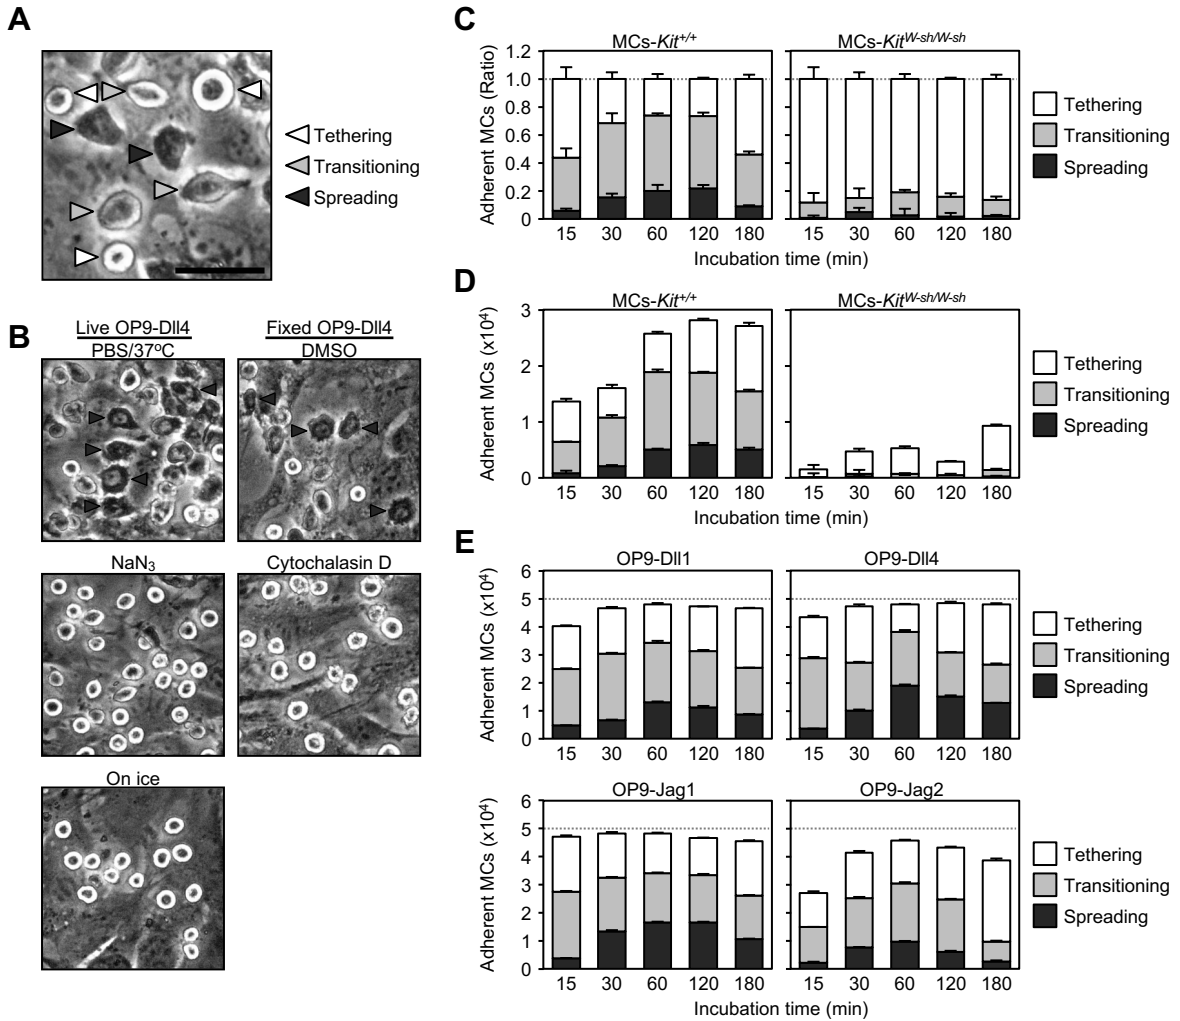

1 0 (total MCs initially added) were shown. (A) The survival responses of each MC on  
2 each OP9 cell or without OP9 cells (OP9(-)). Data are the mean  $\pm$  S.E. of triplicate  
3 cultures ( $*p < 0.05$ , one-way ANOVA with Tukey's HSD test). Asterisks in the bars  
4 denote significant differences in the response on each OP9 cell from that on each  
5 OP9-Ctrl cell. (B) The responses of each MC on OP9-Ctrl cells with or without 10  
6  $\mu\text{g/mL}$  of an anti-CD4 mAb (GK1.5, for control) or anti-Kit mAb (ACK2). Data are the  
7 mean  $\pm$  S.E. of triplicate cultures.  $*p < 0.05$ , one-way ANOVA with Tukey's HSD test.  
8 n.s.: not significant. (C) The responses of MCs-*Kit*<sup>+/+</sup> on OP9-Ctrl cells with SB203580  
9 (SB, 40  $\mu\text{M}$ ), PD98059 (PD, 40  $\mu\text{M}$ ), LY294002 (LY, 20  $\mu\text{M}$ ), or the solvent DMSO  
10 (0.2% vol/vol). Data are the mean  $\pm$  S.E. of triplicate cultures.  $*p < 0.05$ , one-way  
11 ANOVA with 2-tailed Dunnett's pairwise multiple comparison *t*-test.  
12

13 **Figure 7.** Summary of Kit- and Notch-mediated cell adhesion. The tethering of MCs to  
14 stromal cells is induced by Kit-Kitl and Notch receptor-ligand interactions (26). Kit  
15 signaling activates the PI3K and MAPKs pathways, leading to the induction of integrin  
16 activation and cytoskeletal reorganization, which enables MCs to spread (15-24). The  
17 Notch-mediated tethering of MCs leads to the activation of the above signaling pathway  
18 that induces the spreading of adherent MCs as Kit-mediated adhesion, in a manner  
19 independent of the  $\gamma$ -secretase activity. The mechanisms by which the PI3K and  
20 MAPKs pathways are activated during Notch-mediated adhesion remain unclear;  
21 however,  $\gamma$ -secretase-independent non-canonical Notch signaling (50-52) may be  
22 involved: (A), non-canonical signaling may directly activate PI3K (53-55), and (B)  
23 Notch signaling may indirectly influence signaling from other RTKs to modulate the  
24 activation of MAPKs (56-66). Kit supports the adhesion and survival of MCs, whereas  
25 Notch only supports adhesion (Table).

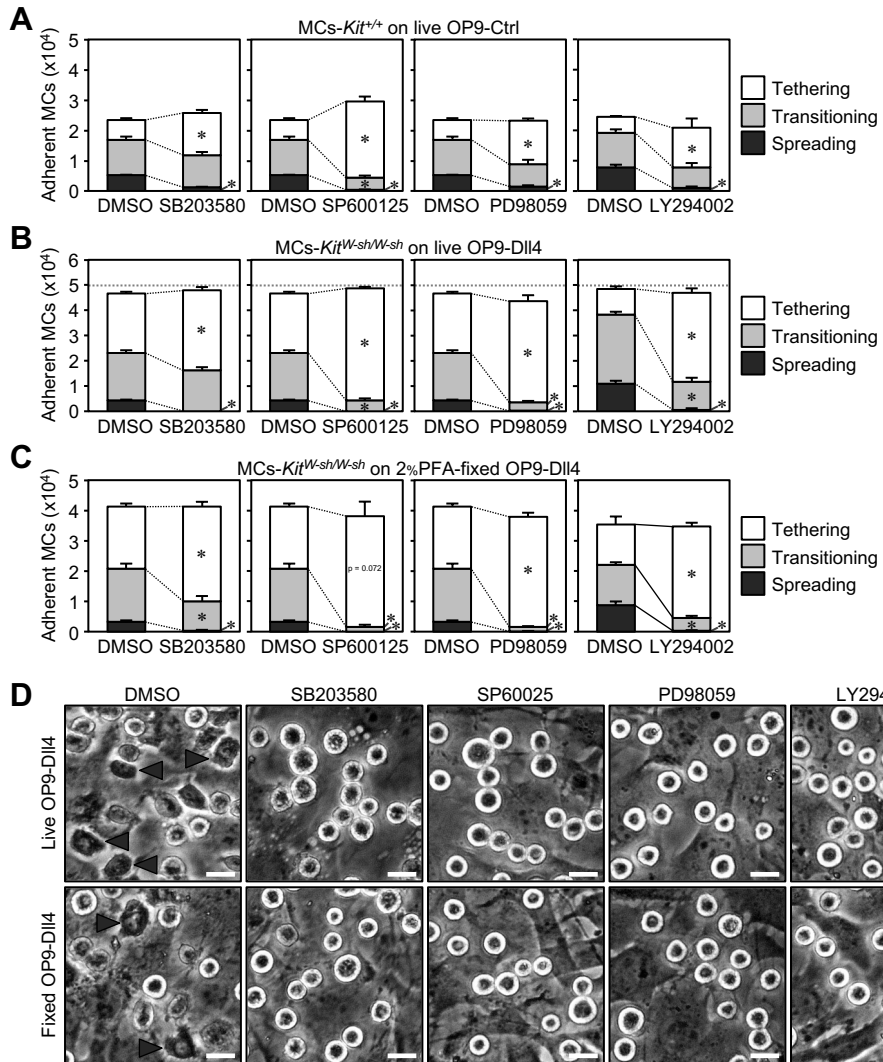

**Figure 3**

**Figure 4**

**Figure 5**

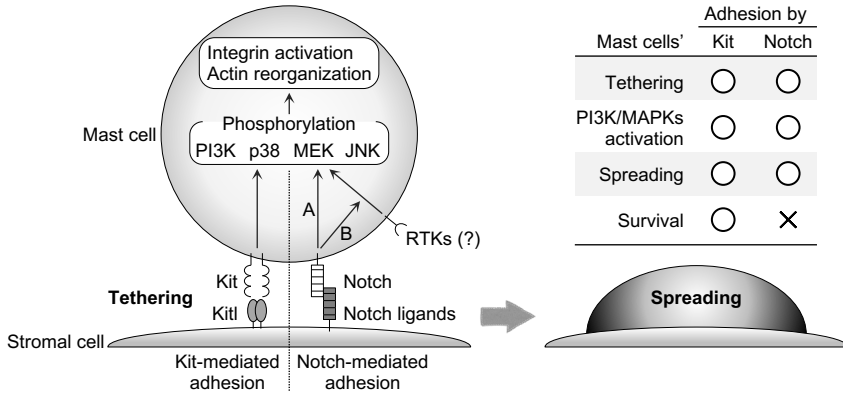

**Figure 6**

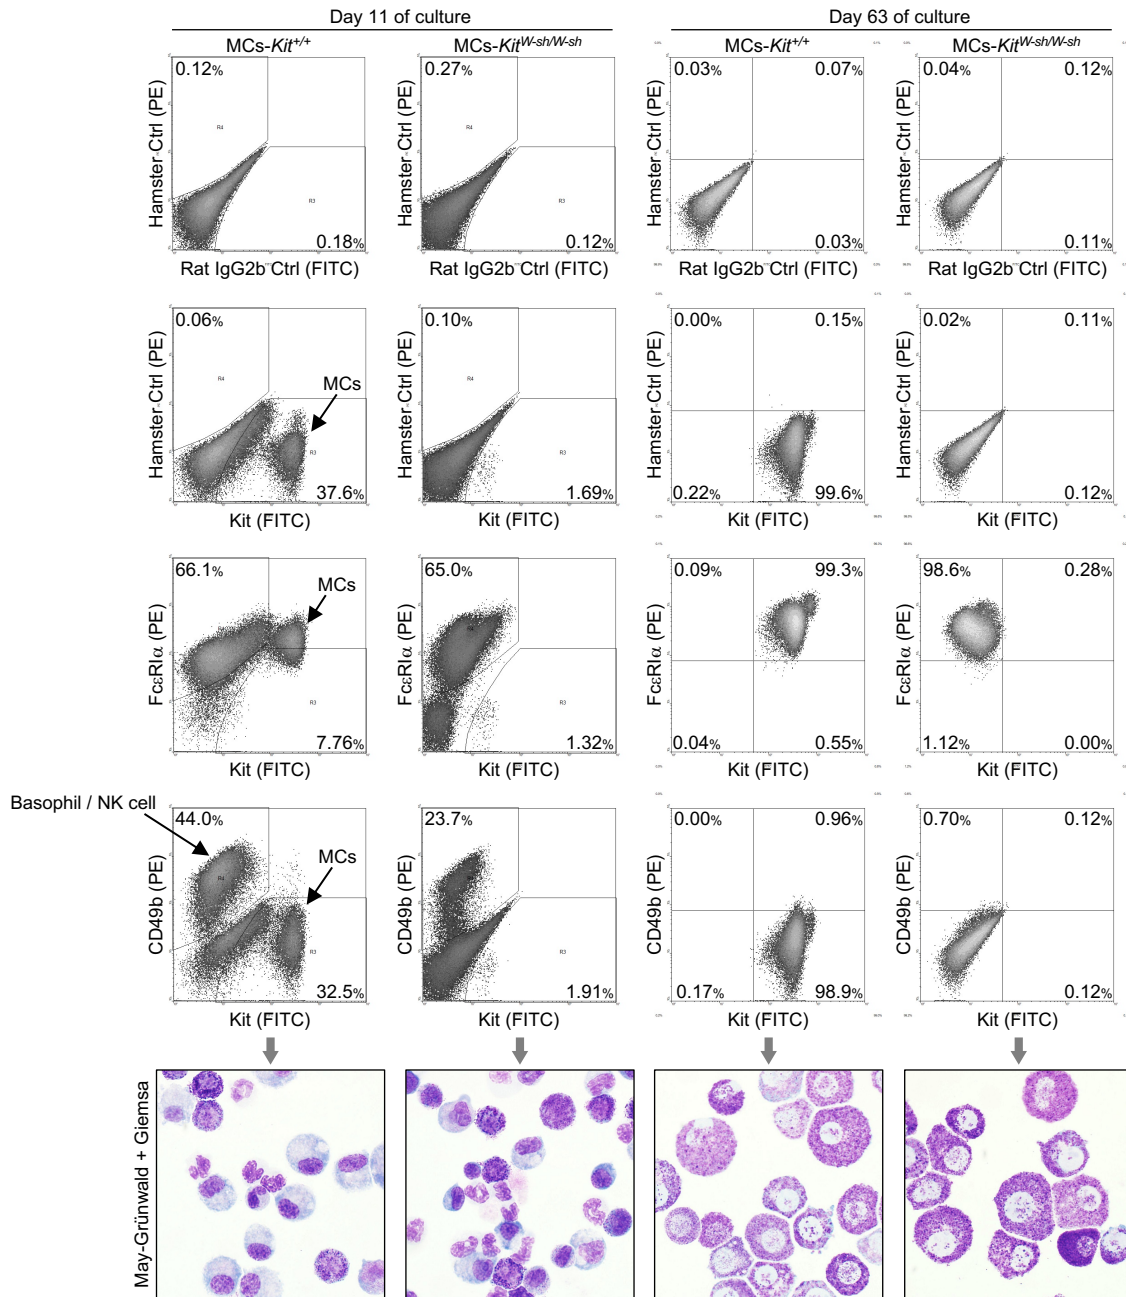

# Figure 7

# Supplemental Figure 1

**Fig. S1.** Mice-Kit<sup>W-sh/W-sh</sup> are MCs, not basophils.

On days 11 and 63 of the induction of MCs from the bone marrow cells of C57BL/6-Kit<sup>+/+</sup> and -Kit<sup>W-sh/W-sh</sup> mice, the expression of Kit, FcεRIα, and CD49b (DX5, basophil, and NK cell marker) was analyzed by flow cytometry. On day 11 of the Mice-Kit<sup>+/+</sup> culture, when MCs and basophils co-exist (I), CD49b<sup>+</sup> cells were detected in the Kit<sup>-</sup> fraction, whereas Kit<sup>+</sup> cells were FcεRIα<sup>+</sup>CD49b<sup>-</sup>. The Mice-Kit<sup>W-sh/W-sh</sup> culture also contained CD49b<sup>+</sup> cells. On day 63 of both cultures, most of the cells were FcεRIα<sup>+</sup>CD49b<sup>-</sup>. Histochemistry with May-Grünwald and Giemsa solution (Muto Pure Chemicals, Tokyo, Japan) showed that all cells in both cultures on day 63 had similar morphologies and granulation, suggesting that cells in both cultures are MCs.

## Supplemental Figure 2

**Fig. S2.** Staining of Peritoneal MCs and bone marrow-derived MCs

(A) Detection of peritoneal mast cells (related to Figure 1D).  $Kit^{hi}$  cells in the peritoneal exudate cells of C57BL/6- $Kit^{+/+}$  mice expressed  $Fc\epsilon RI\alpha$ . MC-deficient C57BL/6- $Kit^{W-sh/W-sh}$  mice lacked this population, suggesting that they are MCs. (B) Histocytochemistry of MCs- $Kit^{+/+}$  and - $Kit^{W-sh/W-sh}$  (84 days of culture) and peritoneal exudate cells from C57BL/6- $Kit^{+/+}$  and - $Kit^{W-sh/W-sh}$  mice. Alcian blue + Safranin O: cells were initially stained with Alcian blue (pH 2.5), and then with 0.1% safranin O (Muto Pure Chemicals). Naphthol AS-D chloroacetate esterase (CAE): Cells were stained with CAE staining kit (Sigma-Aldrich) according to the manufacturer's instruction. Peritoneal MCs (C57BL/6- $Kit^{+/+}$ ) were mature connective tissue-type MCs (II), as shown by red staining with safranin O and CAE staining (red) (III). In contrast, MCs- $Kit^{+/+}$  and - $Kit^{W-sh/W-sh}$  were immature mucosal-type MCs (II), as shown by blue staining with Alcian blue and weak to negative staining with CAE. Arrows: peritoneal MCs. Bars: 25  $\mu$ m.

### Supplemental Figure 3

**Fig. S3.** Original gel sources and negative controls related to Figures 1E and 1F.

(A) Original gel sources for Figure 1E. (B) Negative control for the RT-PCR analysis related to Figure 1E and (A). RT(-) denotes PCR with total RNA subjected to the reverse-transcription reaction without a RT enzyme. (C) Original gel source and the negative control for *Kitl* in Figure 1F. (D) Original gel source for *Kit* and *Fcer1a* in Figure 1F.

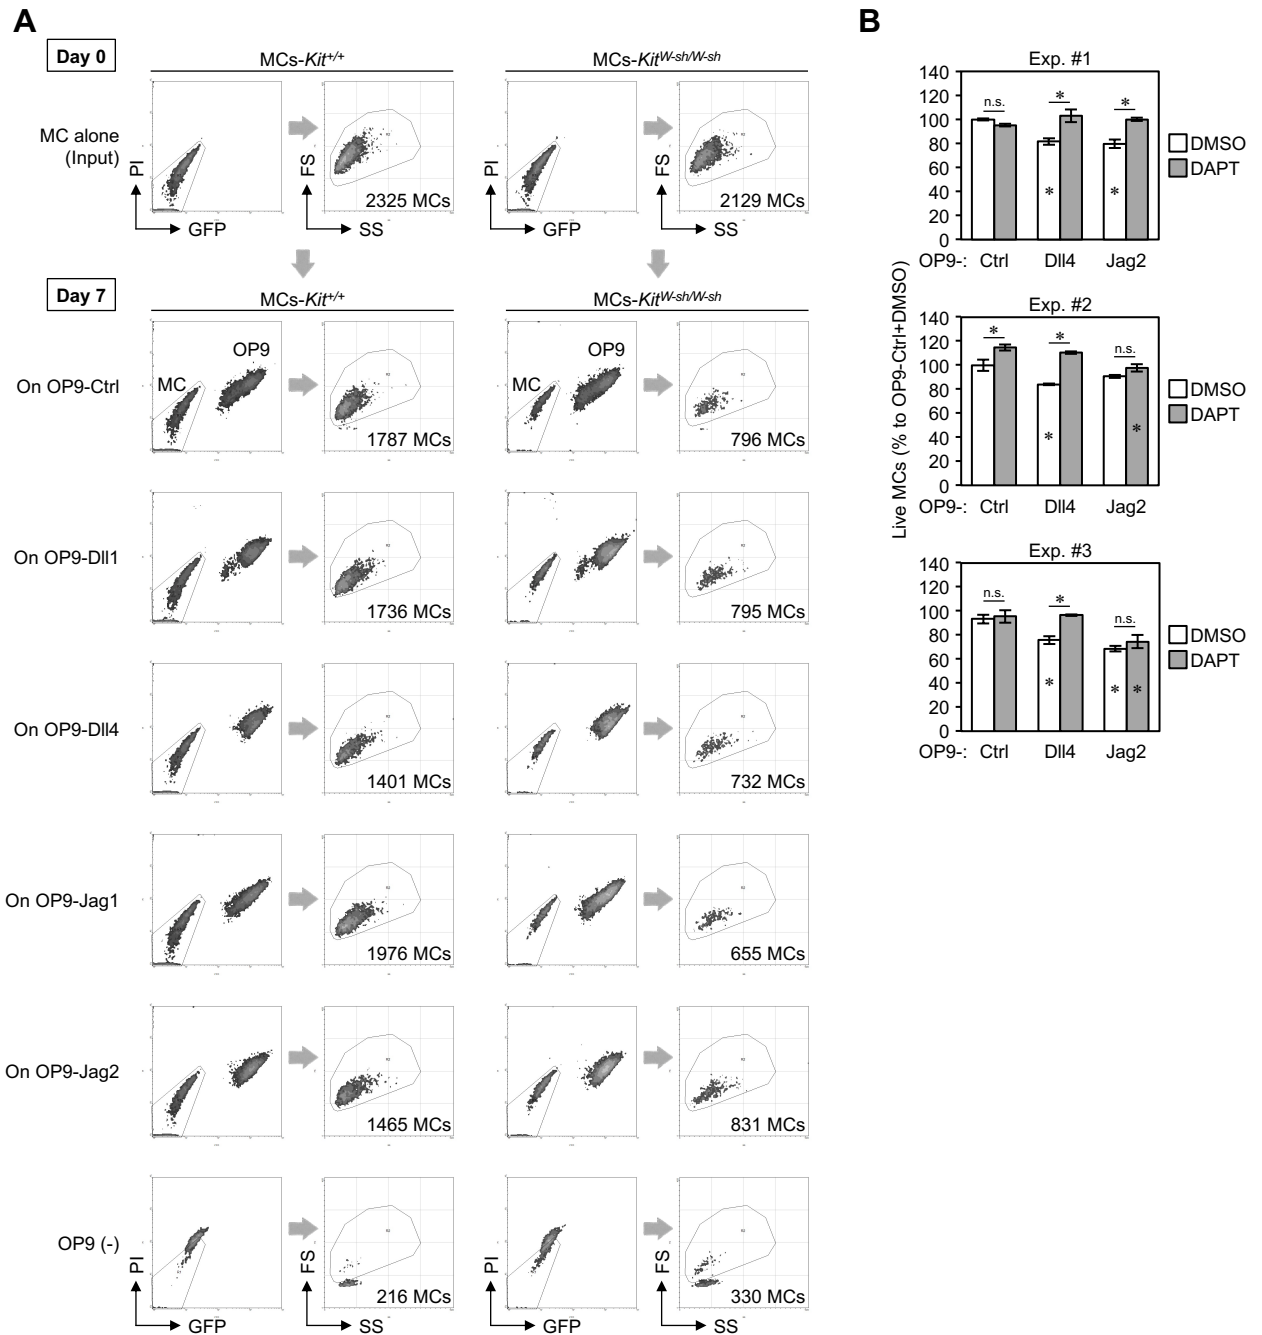

## Supplemental Figure 4

**Fig. S4.** Notch-dependent spreading of adherent MCs-Kit<sup>W-sh/W-sh</sup> involved MAPKs and PI3K signaling in MCs.

MCs-Kit<sup>W-sh/W-sh</sup> were pretreated with SB203580 (p38 inhibitor, 50  $\mu$ M), SP600125 (JNK inhibitor, 50  $\mu$ M), PD98059 (MEK1/2 inhibitor, 50  $\mu$ M), LY294002 (PI3K inhibitor, 20  $\mu$ M), or the solvent DMSO (0.25% vol/vol) for 60 min, and adhesion assays (60 min) were performed with the reagents on the indicated OP9 stromal cells. Dotted lines indicate the total number of MCs plated on the wells. Asterisks denote the significantly different responses of each adhesion state from control treatments ( $p < 0.05$ , 1-tailed Welch's  $t$ -test).

# Supplemental Figure 5

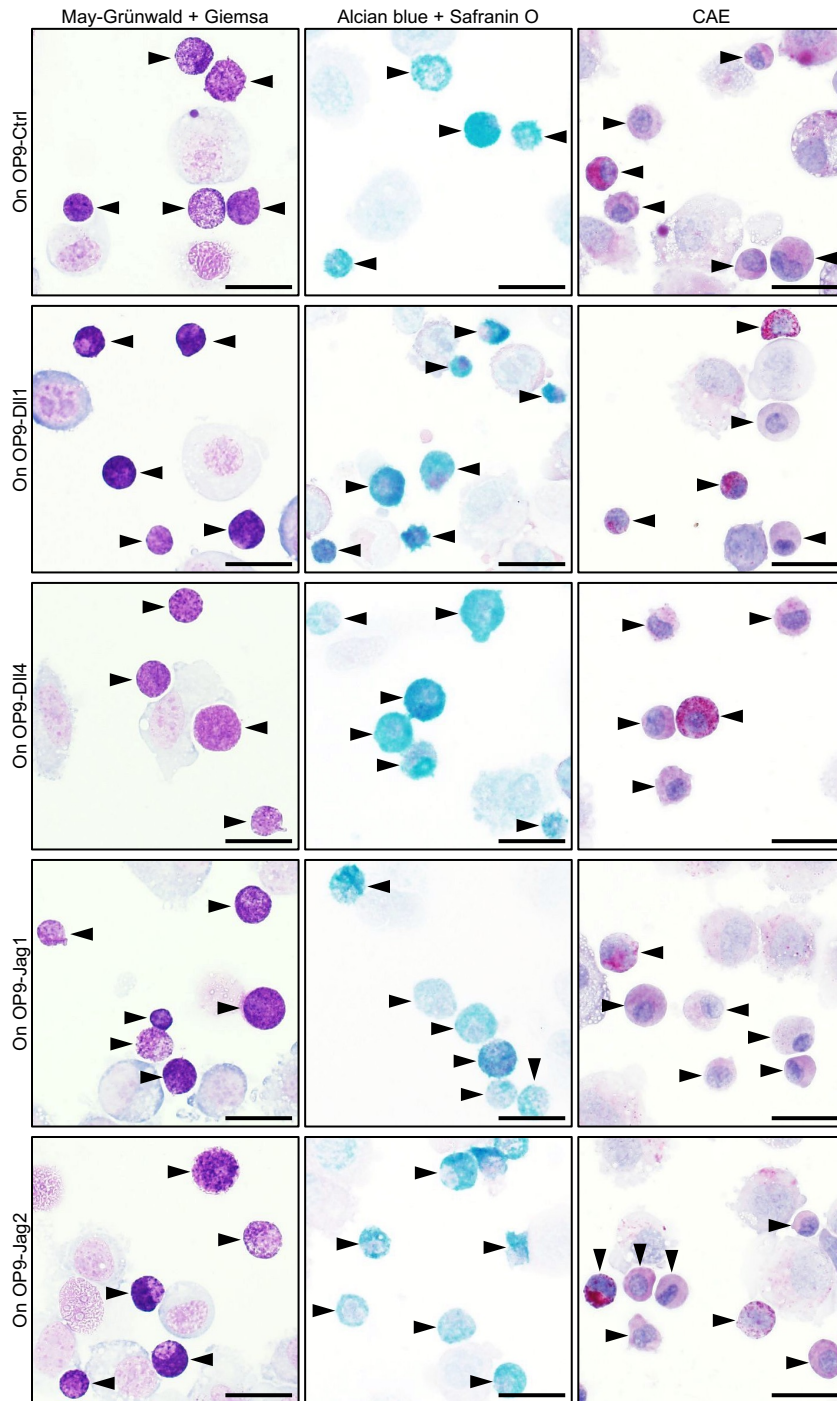

**Fig. S5.** Notch signaling may negatively affect the survival of *MCs-Kit*<sup>+/+</sup> on OP9-Dll4 and -Jag2.

(A) Detection of live MCs after a 7-day co-culture with each OP9 stromal cell by flow cytometry. On day 7 of the co-culture, all cells in the wells were harvested with trypsinization, stained with PI, and analyzed by flow cytometry. GFP-PI<sup>-</sup> cells in the 60-second flow were counted as live MCs. Representative histograms were shown. (B) *MCs-Kit*<sup>+/+</sup> were cultured on the indicated OP9 cell for 7 days with DAPT (20 μM) or the same volume of DMSO (0.1% vol/vol), and the number of surviving MCs was analyzed. Percent control responses to the response of OP9-Ctrl+DMSO in 3 independent experiments were shown. Data are the mean ± S.E. of triplicate cultures. \* *p* < 0.05, one-way ANOVA with Tukey's HSD test. n.s.: not significant. Asterisks in the bars indicate significant differences from each response on OP9-Ctrl.

## Supplemental Figure 6

MCs-Kit<sup>+/+</sup> cultured on each OP9 transductant for 7 days

**Fig. S6.** Granule contents of MCs-Kit<sup>+/+</sup> did not show marked changes after a co-culture with each OP9 transductant.

After culturing MCs-Kit<sup>+/+</sup> on each OP9 transductant for 7 days, cells (OP9 cells + MCs) were harvested and stained with the indicated reagents. Co-cultured MCs-Kit<sup>+/+</sup> still showed blue staining with Alcian blue and weak to negative staining with CAE, suggesting that Notch-mediated cell adhesion did not influence the maturation of MCs-Kit<sup>+/+</sup> during the co-culture (compare with peritoneal mature MCs in Supplemental Figure 2). Arrows: MCs. Bars: 25  $\mu$ m.
