# Incremental Checking of Well-Founded Recursive Specifications Modulo Axioms^ 

Felix Schernhammer ${ }^{1}$ and José Meseguer ${ }^{2}$<br>${ }^{1}$ Vienna University of Technology, Austria, felixs@logic.at<br>${ }^{2}$ University of Illinois at Urbana-Champaign, USA, meseguer@uiuc.com

#### Abstract

We introduce the notion of well-founded recursive order-sorted equational logic (OS) theories modulo axioms. Such theories define functions by well-founded recursion and are inherently terminating. Moreover, for well-founded recursive theories important properties such as confluence and sufficient completeness are modular for so-called fair extensions. This enables us to incrementally check these properties for hierarchies of such theories that occur naturally in modular rule-based functional programs. Well-founded recursive OS theories modulo axioms contain only commutativity and associativity-commutativity axioms. In order to support arbitrary combinations of associativity, commutativity and identity axioms, we show how to eliminate identity and (under certain conditions) associativity (without commutativity) axioms by theory transformations in the last part of the paper.

## 1 Introduction

Scalability is a big, unsolved challenge in formal reasoning about executable algebraic specifications. When using such specifications as programs and reasoning about their correctness, we often need to check basic properties such as confluence, termination, and sufficient completeness. This is quite manageable for small specifications, but when dealing with larger specifications corresponding to realistic programs, we can encounter severe tool performance barriers. For example, a non-built-in specification in Maude of the natural numbers, which is the exact counterpart of Maude's built-in NAT module, cannot be proved terminating by the MTT tool, which performs a relatively simple transformation to make the order-sorted specification unsorted and then invokes the AProVE tool with a 900 second timeout. Likewise, Mu-term cannot prove the same specification terminating with the same timeout, even though both AProVE and Mu-Term are state-of-the-art tools. In a similar way, particularly in the presence of AC axioms, a large number of critical pairs is often generated when checking the local confluence of specifications. For example, a small AC specification of hereditarily finite sets with only 26 equations already generates 1027 critical pairs when using the Maude Church-Rosser Checker [10]. Modularity is crucial.

Modular methods for termination and confluence (for a good survey up to 2002 see [24]) are certainly helpful. However: (i) some of these methods make quite strong requirements (e.g., disjointness) on the kind of modularity they allow; (ii) little seems to be known about the modularity of sufficient completeness; and (iii) the modularity results we are aware of do not deal with sorts and subsorts, nor (except for, e.g., $[23,19]$ ) with rewriting modulo axioms, which are key features of state-of-the-art rule-based languages such as ASF + SDF [30], ELAN [5], CafeOBJ [11], and Maude [6].

Our Approach is based on the observation that in practice algebraic specifications are often recursive function definitions based on constructor patterns, and whose right-hand sides involve recursive calls to the same and/or previously defined functions on smaller arguments in the wellfounded subterm ordering. This includes, but goes beyond, the very common case of primitiverecursive definitions. For example, the equations defining Ackerman's function,

$$
\begin{array}{r}
A(0, n)=s(n) \quad A(s(m), 0)=A(m, 1) \\
A(s(m), s(n))=A(m, A(s(m), n))
\end{array}
$$

[^0]exemplify a well-founded recursive function definition based on natural number constructor patterns which is not primitive-recursive. Such specifications define total (i.e., terminating) functions on the set of constructor terms. Furthermore, they naturally form hierarchies, so that previously-defined functions can be used to define more complex ones. For example, natural number exponentiation can be recursively defined in terms of multiplication, which can in turn be recursively defined in terms of addition.

The main goal of this work is to reduce the checking of confluence, termination, and sufficient completeness for algebraic specifications based on well-founded recursive function definitions to relatively simple incremental checks on the module hierarchies containing such definitions. However, in order to be practically useful for rule-based languages, the notion of well-founded recursive function definition needs to be generalized to support: (a) mutually recursive definitions; (b) sorts, subsorts, and subsort overloading of function symbols; and (c) rewriting modulo axioms such as associativity and/or commutativity and/or identity. Such a generalization is non-trivial. Support for (a) is the least problematic, but support for (b) means that, because of subsort overloading, a function $f$ can never be considered to be defined once and for all: it can always be extended to bigger sorts. For example, we can first define $a+$ function in a NAT module, and then extend its domain of definition in INT, RAT, and COMPLEX modules. Support for (c) is the least obvious, because the notion of "well-founded recursive function definition" does not have a straightforward extension to the modulo case. For example, if $f$ is an associative-commutative (AC) function symbol, a definition of $f$ based on a binary constructor $g$ and a constructor constant $a$ might include an equation $f(g(x, y), a)=g(f(x, y), g(a, a))$, which syntactically satisfies all the expected requirements of well-founded recursive function definitions, yet is non- $A C$-terminating (cf. Example 5 in Section 3). A related difficulty for axioms like AC is that the usual syntactic characterizations of classes of recursive functions (e.g., primitive recursive) are no longer adequate, because of the much greater flexibility in the constructor patterns that can be used. For example, the definition of the cardinality function card in the MSET-NAT module below could just as well have used an equation $\operatorname{card}\left(\right.$ MS $^{\prime}$, MS' $\left.^{\prime}\right)=\operatorname{card}(M S)+\operatorname{card}\left(\right.$ MS' $\left.^{\prime}\right)$ with MS, MS' of sort MSet, instead of the equation $\operatorname{card}(N, M S)=s(0)+\operatorname{card}(M S)$ with $N$ of sort Nat below. This work provides a notion of well-founded recursive function definition supporting features (a)-(b)-(c). We show in Section 3.1 that our approach generalizes an already very general notion of many-sorted well-founded recursive function.

To make the approach scalable, the cost of each incremental check should be small. This can be achieved by taking advantage of modular methodologies which ensure that in an immediate submodule inclusion $(\Sigma, E \cup A x) \subset\left(\Sigma \cup \Sigma_{\Delta},\left(E \cup E_{\Delta}\right) \cup\left(A x \cup A x_{\Delta}\right)\right)$, while both modules can be arbitrarily large, the incremental additions $\Sigma_{\Delta}$ to the signature, $E_{\Delta}$ to the defining equations, and $A x_{\Delta}$ to the axioms, are small. Such increments being big is a clear sign of bad software engineering practice, since usually a more modular design can be achieved by module refactoring. The incremental proof methods we propose are scalable precisely because they are based on checking the typically small increments $\left(\Sigma_{\Delta}, E_{\Delta} \cup A x_{\Delta}\right)$ and not the, potentially very large, theory ( $\Sigma \cup$ $\left.\Sigma_{\Delta},\left(E \cup E_{\Delta}\right) \cup\left(A x \cup A x_{\Delta}\right)\right)$.

A Running Example. Throughout the paper we use the following running example in Maude. Although small, it illustrates all the key features supported: mutual recursion, order-sortedness, and rewriting modulo axioms.

```
fmod NATURAL is pr TRUTH-VALUE .
    sort Nat .
    op 0 : -> Nat [ctor] .
    op s : Nat -> Nat [ctor] .
    op _+_ : Nat Nat -> Nat [comm id: 0] .
    ops even odd : Nat -> Bool .
    vars N M : Nat .
    eq }s(N)+s(M)=s(s(N+M))
    eq even(0) = true .
    eq even(s(N)) = odd(N).
    eq odd(0) = false.
    eq odd(s(N)) = even(N).
endfm
```

```
fmod MSET-NAT is pr NATURAL .
    sort MSet .
    subsort Nat < MSet .
    op _,_ : MSet MSet _> MSet [ctor assoc comm id: null] .
    op null : -> MSet [ctor].
    op card : MSet -> Nat .
    var MS : MSet .
    var N : Nat .
    eq card(null) = 0 .
    eq card(N,MS)=s(0) + card(MS) .
endfm
fmod LIST-MSET-NAT is pr MSET-NAT .
    sorts List NeList .
    subsorts MSet < NeList < List .
    op nil : -> List [ctor] .
    op U : List -> MSet .
    op _;_ : List List -> List [assoc id: nil] .
    op _;_ : MSet NeList -> NeList [ctor assoc id: nil] .
    var MS : MSet .
    var NL : NeList.
    eq U(nil) = null .
    eq U(MS) = MS .
    eq U(MS ; NL) = MS, U(NL).
endfm
```

The NATURAL module defines the natural numbers with addition and with even and odd predicates. The MSET-NAT module defines multisets of naturals and cardinality of multisets. Finally, the LIST-MSET-NAT module forms lists of multisets of numbers and defines a multiset union operator on such lists. Associativity, commutativity and identity axioms are specified with the assoc, comm, and id: attributes. All constructor operators are declared with the ctor keyword. As illustrated for _ ; , an operator can be a constructor for some typing (NeList) and a defined symbol for a looser typing: $(0,0)$; nil and nil ; nil are not constructor terms.

The paper is organized as follows. Section 2 gives background on order-sorted rewriting. Section 3 introduces well-founded recursive theories. Section 4 describes and justifies the incremental checking methods modulo $C$ and $A C$ axioms. Section 5 extends the approach to other combinations of $A, C$ and $I$ (identity) axioms. Finally, Section 6 discusses related work and presents some conclusions. The proofs of all theorems can be found in the appendix.

## 2 Background on Order-sorted Term Rewriting

We summarize here material from $[14,21]$ on order-sorted algebra and order-sorted rewriting. For standard notions and notations of ordinary term rewriting we refer to [3, 4]. We start with a partially ordered set $(S, \leq)$ of sorts, where $s \leq s^{\prime}$ is interpreted as subsort inclusion. The connected components of $(S, \leq)$ are the equivalence classes $[s]$ corresponding to the least equivalence relation $\equiv \leq$ containing $\leq$. When a connected component $[s]$ has a top element, we will also denote by $[s]$ such a top element. An order-sorted signature $\Sigma=(S, \leq, F)$ consists of a poset of sorts $(S, \leq)$ and a $S^{*} \times S$-indexed family of sets $F=\left\{F_{w, s}\right\}_{(w, s) \in S^{*} \times S}$, which are function symbols with given string of argument sorts and result sort. If $f \in F_{s_{1} \ldots s_{n}, s}$, we declare the function symbol $f$ as $f: s_{1} \ldots s_{n} \longrightarrow s$. Some of these symbols $f$ can be subsort-overloaded, i.e., they can have several declarations related in the $\leq$ ordering [14].

Given an $S$-sorted set $\mathcal{X}=\left\{\mathcal{X}_{s} \mid s \in S\right\}$ of disjoint sets of variables and an order-sorted (OS) signature $\Sigma=(S, \leq, F)$, the set $\mathcal{T}(\Sigma, \mathcal{X})_{s}$ of terms of sort $s$ is the least set such that $\mathcal{X}_{s} \subseteq \mathcal{T}(\Sigma, \mathcal{X})_{s}$; if $s^{\prime} \leq s$, then $\mathcal{T}(\Sigma, \mathcal{X})_{s^{\prime}} \subseteq \mathcal{T}(\Sigma, \mathcal{X})_{s}$; and if $f: s_{1} \ldots s_{n} \longrightarrow s$ is a declaration for symbol $f$ and $t_{i} \in \mathcal{T}(\Sigma, \mathcal{X})_{s_{i}}$ for $1 \leq i \leq n$, then $f\left(t_{1}, \ldots, t_{n}\right) \in \mathcal{T}(\Sigma, \mathcal{X})_{s}$. The set $\mathcal{T}(\Sigma, \mathcal{X})$ of order-sorted terms is $\mathcal{T}(\Sigma, \mathcal{X})=\cup_{s \in S} \mathcal{T}(\Sigma, \mathcal{X})_{s}$. An element of any set $\mathcal{T}(\Sigma, \mathcal{X})_{s}$ is called a well-formed term. A simple syntactic condition on $\Sigma$ called preregularity [14] ensures that each well-formed term $t$ has always a least-sort possible among all sorts in $S$, which is denoted $l s(t)$.

Furthermore, $\Sigma$ is monotonic if for every two declarations $f: s_{1} \ldots s_{n} \longrightarrow s$ and $f: s_{1}^{\prime} \ldots s_{n}^{\prime} \longrightarrow s^{\prime}$, $s_{1} \ldots s_{n} \gtrdot s_{1}^{\prime} \ldots s_{n}^{\prime}$ implies $s>s^{\prime}$, where $s_{1}, \ldots, s_{n} \gtrdot s_{1}^{\prime}, \ldots, s_{n}^{\prime}$ means $s_{i} \geq s_{i}^{\prime}$ for all $1 \leq i \leq n$ and $s_{i}>s_{i}^{\prime}$ for some $1 \leq i \leq n$. Throughout this paper we assume that all order-sorted signatures are preregular and monotonic. Terms are viewed as labeled trees in the usual way. Positions $p, q, \ldots$ are represented by chains of positive natural numbers used to address subterm positions of $t$. The set of positions of a term $t$ is denoted $\mathcal{P} o s(t)$. Positions of non-variable symbols in $t$ are denoted as $\mathcal{P o s}_{\Sigma}(t)$, and $\mathcal{P o s}_{\mathcal{X}}(t)$ are the positions of variables. The subterm at position $p$ of $t$ is denoted as $\left.t\right|_{p}$ and $t[u]_{p}$ is the term $t$ with the subterm at position $p$ replaced by $u$. We write $t \unrhd u$, read $u$ is a subterm of $t$, if $u=\left.t\right|_{p}$ for some $p \in \mathcal{P o s}(t)$ and $t \triangleright u$ if $t \unrhd u$ and $t \neq u$.

An order-sorted substitution $\sigma$ is an $S$-sorted mapping $\sigma=\left\{\sigma: \mathcal{X}_{s} \rightarrow \mathcal{T}(\Sigma, \mathcal{X})_{s}\right\}_{s \in S}$ from variables to terms. A specialization $\nu$ is an OS-substitution that maps a variable $x$ of sort $s$ to a variable $x^{\prime}$ of sort $s^{\prime} \leq s$. We denote $\mathcal{D o m}(\sigma)$ and $\mathcal{R} n g(\sigma)$ the domain and range of a substitution $\sigma$. An (order-sorted) rewrite rule is an ordered pair $(l, r)$, written $l \rightarrow r$, with $l, r \in \mathcal{T}(\Sigma, \mathcal{X})$, $l \notin \mathcal{X}, \mathcal{V} a r(r) \subseteq \mathcal{V} \operatorname{ar}(l)$ (and $l s(l) \equiv \leq l s(r)$ for order-sorted rules). If for all specializations $\nu$, $l s(\nu(l)) \geq l s(\nu(r))$, then we say that the OS-rule $l \rightarrow r$ is sort-decreasing. A term $t \in \mathcal{T}(\Sigma, \mathcal{X})$ rewrites to $u$ (at position $p \in \mathcal{P} o s(t)$ and using the rule $l \rightarrow r$ ), written $t{ }^{p}{ }_{l \rightarrow r} s$ (or just $t \rightarrow_{\mathcal{R}} s$ or even $t \rightarrow s$ if no confusion arises), if $\left.t\right|_{p}=\sigma(l)$ and $s=t[\sigma(r)]_{p}$, for some OS-substitution $\sigma$; if $l \rightarrow r$ is not sort-decreasing, we also require that $t[\sigma(r)]_{p}$ is a well-formed term.

An order-sorted theory (OS theory) is a triple $\mathcal{E}=(\Sigma, B, R)$ with $\Sigma$ a preregular order-sorted signature such that each connected component has a top sort, $B$ a set of unconditional $\Sigma$-equations, and $R$ a set of unconditional $\Sigma$-rules. In this paper $B$ will always be a combination of associativity and/or commutativity and/or identity axioms for some of the operators in $\Sigma$. Moreover, associative and commutative operators $f$ are always typed $f: s s^{\prime} \longrightarrow s$ for some sorts $s, s^{\prime}$ where $s^{\prime} \leq s$. By $\Sigma_{A C}$ (resp. $\Sigma_{C}$ ) we denote the subsignature of $\Sigma$ where all function symbols are associative and commutative but do not have an identity (resp. where all function symbols are commutative but not associative and do not have an identity). Furthermore, we assume ${ }^{3}$ that in each equation $u=v$ in $B$ the variables $\left\{x_{1}, \ldots, x_{n}\right\}=\mathcal{V}$ ar $(u)=\mathcal{V}$ ar $(v)$ have top sorts $\left[s_{1}\right], \ldots,\left[s_{n}\right]$.

Given an OS theory $\mathcal{E}$ as above, $t \rightarrow_{R / B} t^{\prime}$ iff there exist $u, v$ such that $t=_{B} u$ and $u \rightarrow_{R} v$ and $v={ }_{B} t^{\prime}$. We say that $(\Sigma, B, R)$ is $B$-confluent, resp. B-terminating, if the relation $\rightarrow_{R / B}$ is confluent, resp. terminating. By $[w]_{B}$ we denote that equivalence class of terms that are $B$-equal to $w$. We call an order-sorted signature $B$-preregular if the set of sorts $\left\{s \in S \mid \exists w^{\prime} \in[w]_{B}\right.$ s.t. $w^{\prime} \in$ $\left.\mathcal{T}(\Sigma, \mathcal{X})_{s}\right\}$ has a least upper bound, denoted $l s[w]_{B}$ which can be effectively computed. ${ }^{4}$ If $(\Sigma, B, R)$ is $B$-confluent, $B$-terminating, $B$-preregular, and sort-decreasing, then the initial algebra $\mathcal{T}_{\Sigma / R \cup B}$, where the rules $R$ are interpreted as equations, is isomorphic to the canonical term algebra $\mathcal{C}_{\Sigma / R, B}$, whose elements are $B$-equivalence classes in $\rightarrow_{R / B}$-canonical form. An order-sorted subsignature $\Omega \subseteq \Sigma$ with the same poset of sorts as $\Sigma$ is called a constructor subsignature iff for each ground $\Sigma$-term $t$ there is a ground $\Omega$-term $u$ such that $t \rightarrow_{R / B}^{*} u$. Terms from $\mathcal{T}(\Omega, \mathcal{X})$ are called $\Omega$ constructor terms, or just constructor terms if $\Omega$ is clear from the context. We then say that $(\Sigma, B, R)$ is sufficiently complete with respect to $\Omega$. Intuitively this means that the functions defined by the rules $R$ have been fully defined. For instance, the operators declared with the ctor attribute in our running example define a constructor subsignature, so that the specification is sufficiently complete. Assuming that $(\Sigma, B, R)$ is $B$-confluent, $B$-terminating, $B$-preregular, and sort-decreasing, and that $\Omega$ is a constructor subsignature, if for any $t \rightarrow t^{\prime}$ in $R$, whenever $t$ is an $\Omega$-term then $t^{\prime}$ is also an $\Omega$-term, we are then guaranteed that all the elements in the canonical term algebra $\mathcal{C}_{\Sigma / R, B}$ are $B$-equivalence classes of ground $\Omega$-terms. If, in addition, any ground $\Omega$-term $t$ is in $\rightarrow_{R / B^{-}}$-canonical form, then we call $\Omega$ a signature of free constructors modulo $B$.

Given an OS theory $\mathcal{E}=(\Sigma, B, R)$, we call an unsorted theory $\mathcal{E}^{\prime}=\left(\Sigma^{\prime}, B^{\prime}, R^{\prime}\right)$ a sound reflection of $\mathcal{E}$ if there exists a mapping $\mathcal{M}$ from $\mathcal{T}(\Sigma, \mathcal{X})$ to a set of unsorted terms such that $t \rightarrow_{R / B} t^{\prime} \Rightarrow \mathcal{M}(t) \rightarrow_{R^{\prime} / B^{\prime}}^{+} \mathcal{M}\left(t^{\prime}\right)$ for all terms $t, t^{\prime} \in \mathcal{T}(\Sigma, \mathcal{X})$ (in that case we say that $\mathcal{E}^{\prime}$ is a

[^1]sound reflection of $\mathcal{E}$ w.r.t. $\mathcal{M}$; cf. [25]). Given a strict order $\succ$ on some domain $D$, the lexicographic extension of $\succ$ to $n$-tuples over $D$ is defined as $\left\langle d_{1}, \ldots, d_{n}\right\rangle \succ^{l e x}\left\langle d_{1}^{\prime}, \ldots, d_{n}^{\prime}\right\rangle$ if there exists an $i \leq n$ such that $d_{j}=d_{j}^{\prime}$ for all $j<i$ and $d_{i} \succ d_{i}^{\prime}$. Moreover, the multiset extension of $\succ$ to multisets over $D$ is defined by $D_{1} \succ^{m u l} D_{2}$ if $D_{1} \neq D_{2}$ and for each $d \in D_{2} \backslash D_{1}$ there exists a $d^{\prime} \in D_{1} \backslash D_{2}$ such that $d^{\prime} \succ d$.

## 3 Well-founded Recursive Theories

In this section we introduce the notion of well-founded recursive OS theories modulo axioms. The basic idea is to impose conditions on the equations of such theories, that guarantee finiteness of rewrite derivations. These conditions are based on the notion of recursive dependency of function symbols. Intuitively, a function symbol $f$ recursively depends on $g$ if there is a rule $f\left(t_{1}, \ldots, t_{n}\right) \rightarrow r$ in the OS theory with $\operatorname{root}\left(\left.r\right|_{p}\right)=g$ for some position $p$ of $r$.
Definition 1 (recursive dependency). Assume the axioms $B_{0}$ of the theory $\mathcal{E}=\left(\Sigma, B_{0}, R\right)$ are only commutativity and associativity-commutativity axioms. ${ }^{5}$

Let $G$ be the names of function symbols in $\Sigma$. The relation ${ }_{\mathcal{E}}^{1} \subseteq G \times G$ is defined as $f{ }_{\mathcal{E}}^{1} g$ whenever, there is a rule $l \rightarrow r \in R$ and a position $p \in \operatorname{Pos}(r)$ such that $\operatorname{root}(l)=f$ and $\operatorname{root}\left(\left.r\right|_{p}\right)=g$. The preorder $\mathcal{E} \subseteq G \times G$ is obtained as the reflexive and transitive closure of $\mathcal{E}_{\mathcal{E}}^{1}$.

For order-sorted theories, and in particular in the presence of subsort overloaded function symbols, it is advantageous to distinguish between subsort overloaded variants of function symbols, because by doing so one obtains a more fine-grained notion of recursive dependency. This more fine-grained notion is needed because recursive dependencies exclusively based on the names of overloaded function symbols are too coarse to faithfully capture the actual dependencies involved in order-sorted rewriting.

A straightforward approach to achieve this disambiguation of subsort overloaded function symbols is to label them with the sorts of their arguments. This approach was used for instance by Ölveczky et al. ([25][Definitions 2 and 3]) to obtain an unsorted reflection of order-sorted rewrite systems. Unfortunately, in the presence of associativity axioms the unsorted rewrite system obtained by this labeling may not reflect the original order-sorted one.

Example 1. Consider an OS theory $\mathcal{E}$ with sorts $A<B$, a function symbol $f$ which is subsort overloaded with typings $f: A A \rightarrow A$, and $f: B B \rightarrow B$, a unary function symbol $s$ with typing $s: B \rightarrow A$, and a constant $b$ of sort $B$. The symbol $f$ is associative and commutative and the rules are

$$
\begin{aligned}
f(b, x) & \rightarrow f(s(b), s(b)) \\
f(b, s(x)) & \rightarrow f(b, x)
\end{aligned}
$$

where the sort of the variable $x$ is $B$. By labeling the function symbols according to the sorts of their arguments in the corresponding order-sorted rewrite system, one does not obtain a sound reflection. The labeled versions of the above rules (including specializations) are

$$
\begin{aligned}
f_{B, B}(b, x) & \rightarrow f_{A, A}\left(s_{B}(b), s_{B}(b)\right) \\
f_{B, A}(b, x) & \rightarrow f_{A, A}\left(s_{B}(b), s_{B}(b)\right) \\
f_{B, A}\left(b, s_{B}(x)\right) & \rightarrow f_{B, B}(b, x) \\
f_{B, A}\left(b, s_{A}(x)\right) & \rightarrow f_{B, A}(b, x)
\end{aligned}
$$

In [25], additionally rules that decrease the sort labelings of function symbols are needed. Here, these rules are

$$
\begin{aligned}
f_{B, B}(x, y) & \rightarrow f_{A, B}(x, y) \\
f_{B, B}(x, y) & \rightarrow f_{B, A}(x, y) \\
f_{A, B}(x, y) & \rightarrow f_{A, A}(x, y) \\
f_{B, A}(x, y) & \rightarrow f_{A, A}(x, y) \\
s_{B}(x) & \rightarrow s_{A}(x)
\end{aligned}
$$

[^2]The symbols $f_{B, B}, f_{B, A}$ and $f_{A, A}$ are considered to be associative and commutative. The following cyclic reduction sequence cannot be reflected.

$$
\begin{aligned}
& f(f(b, s(b)), b) \rightarrow f(f(s(b), s(b)), b)=_{A C} \\
&={ }_{A C} f(f(b, s(b)), s(b)) \rightarrow \\
& \rightarrow f(f(b, b), s(b))=_{A C} f(f(b, s(b)), b)
\end{aligned}
$$

In fact the labeled rewrite system is terminating (which can automatically be proved by AProVE [13]).

The reason for the inability of the labeled rewrite system to simulate correctly the order-sorted rewriting of Example 1 is the complex interaction between sorts and structural axioms. More precisely, in the term $f(f(s(b), s(b)), b)$ the sort of the arguments of the inner $f$ symbol is $A$. However, in the $A C$-equal term $f(f(b, s(b)), s(b))$ the two arguments of the inner $f$ symbol have sorts $B$ and $A$. Hence, there is an increase in the sorts of the arguments caused by the associativity axiom. Note that in the labeled version of the term $f(f(s(b), s(b)), b)$ which is $f_{A, B}\left(f_{A, A}\left(s_{B}\left(b_{B}\right), s_{B}\left(b_{B}\right)\right), b_{B}\right)$ no associativity equation is applicable since $f_{A, B} \neq f_{A, A}$.

The problem, therefore, is to find a $C$ - and $A C$-compatible disambiguation scheme on which we can express order-sorted recursive dependencies. The solution to this problem is to label $A C$ function symbols not by pairs of sorts, but by the multisets of sorts of arguments of the flattened versions of the terms in question. Commutative (but not associative) function symbols are labeled by unordered pairs of sorts of their arguments.

Definition 2 ((top) flattening). Let $\Sigma$ be an unsorted signature containing free and AC-function symbols and let $f$ be an $A C$ symbol. Then,

$$
\text { flat }(t, f)= \begin{cases}x & \text { if } t=x, \text { a variable } \\ g\left(t_{1}, \ldots, t_{n}\right) & \text { if } t=g\left(t_{1}, \ldots, t_{n}\right), g \neq f \\ f\left(T_{1} \cup T_{2}\right) & \text { if } t=f\left(t_{1}, t_{2}\right)\end{cases}
$$

where

$$
T_{i}=\left\{\begin{array}{l}
\left\{u_{1}, \ldots, u_{m}\right\} \text { if } \operatorname{flat}\left(t_{i}, f\right)=f\left(u_{1}, \ldots, u_{m}\right) \\
\left\{\text { flat }\left(t_{i}, f\right)\right\} \text { otherwise }
\end{array}\right.
$$

Definition 3 (labeled signature, lab). Let $\Sigma=(S,<, F)$ be an order-sorted signature containing $A C, C$ and free function symbols. Its associated unsorted labeled signature $\Sigma^{o s}$ is given by

$$
\begin{aligned}
&\left\{f_{\Psi} \mid\right. f: A B \rightarrow A \in \Sigma_{A C}, \\
&\Psi \text { a finite multiset of sorts } \leq A\} \cup \\
&\left\{f_{\left[A^{\prime}, B^{\prime}\right]} \mid f: A B \rightarrow C \in \Sigma_{C},\left[A^{\prime}, B^{\prime}\right]\right. \text { an unordered } \\
&\text { pair of sorts } \left.A^{\prime} \leq A, B^{\prime} \leq B\right\} \cup \\
&\left\{f_{A_{1}^{\prime}, \ldots, A_{n}^{\prime}} \mid f: A_{1} \ldots A_{n} \rightarrow C \in \Sigma \backslash\left(\Sigma_{C} \cup \Sigma_{A C}\right),\right. \\
&\left.A_{i}^{\prime} \leq A_{i} \text { for all } 1 \leq i \leq n\right\} .
\end{aligned}
$$

For a function symbol $f_{\mathcal{A}}$ of $\Sigma^{o s}$ where $\mathcal{A}$ is a multiset, an unordered pair or a sequence of sorts, we denote by erase $\left(f_{\mathcal{A}}\right)$ the unlabeled function symbol $f$ and by lab $\left(f_{\mathcal{A}}\right)$ the label $\mathcal{A}$.

Note that $\Sigma^{o s}$ is countably infinite in general if $\Sigma$ is countable. Next we define a mapping from terms over $\Sigma$ to terms over the labeled signature $\Sigma^{o s}$.

Definition 4 (labeling terms). Let $\Sigma=(S,<, F)$ be an order-sorted signature containing $A C$, $C$ and free function symbols which is preregular modulo the $A C$ and $C$ axioms. The mapping

न: $\mathcal{T}(\Sigma, V) \rightarrow \mathcal{T}\left(\Sigma^{o s}, V\right)$ is defined by

$$
\bar{t}= \begin{cases}x & \text { if } t=x \in V \\ f_{l s\left(t_{1}\right), \ldots, l s\left(t_{n}\right)}\left(\overline{t_{1}}, \ldots, \overline{t_{n}}\right) & \text { if } t=f\left(t_{1}, \ldots, t_{n}\right), \\ f_{\left[l s\left(t_{1}\right), l s\left(t_{2}\right)\right]}\left(\overline{t_{1}}, \overline{t_{2}}\right) & f \in \Sigma \backslash\left(\Sigma_{C} \cup \Sigma_{A C}\right) \\ f_{\Psi}\left(\lambda\left(t_{1}, f, \Psi\right), \lambda\left(t_{2}, f, \Psi\right)\right) \text { if } t=f\left(t_{1}, t_{2}\right), f \in \Sigma_{C} \\ & \text { flat } \left.(t, f)=f\left(v_{1}, v_{2}\right), f \in \Sigma_{A C}, \ldots, u_{m}\right), \\ & \Psi=\left\{l s\left(u_{1}\right), \ldots, l s\left(u_{m}\right)\right\}\end{cases}
$$

where

$$
\lambda(u, f, \Psi)=f_{\Psi}\left(\lambda\left(u_{1}, f, \Psi\right), \lambda\left(u_{2}, f, \Psi\right)\right)
$$

if $u=f\left(u_{1}, u_{2}\right)$ and $\bar{u}$ otherwise.
Note that, by definition, constants are always labeled by the empty sequence $\epsilon$. Thus, for notational simplicity we omit the label of constants if no confusion arises. Slightly abusing notation, we denote by erase the inverse mapping of ${ }^{-}$, which erases the labels of function symbols and is defined for terms $f\left(t_{1}, \ldots, t_{n}\right) \in \mathcal{T}\left(\Sigma^{o s}, V\right)$ as $\operatorname{erase}(f)\left(\operatorname{erase}\left(t_{1}\right), \ldots, \operatorname{erase}\left(t_{n}\right)\right)$.

Example 2. Consider the signature of $\mathcal{E}$ in Example 1. The labeled term $\overline{f(f(s(b), s(b)), b)}$ is

$$
f_{\{A, A, B\}}\left(f_{\{A, A, B\}}\left(s_{B}(b), s_{B}(b)\right), b\right) .
$$

By labeling terms in equations of an OS theory, we obtain a theory transformation that maps OS theories modulo axioms to unsorted theories modulo axioms.

Definition 5 (labeled theory). Let $\mathcal{E}=\left(\Sigma, B_{0}, R\right)$ be an OS theory with axioms $B_{0}$ including only $C$ and $A C$ axioms. By $\overline{\mathcal{E}}$ we denote the unsorted theory $\left(\Sigma^{o s}, \overline{B_{0}}, \bar{R}\right)$ where

$$
\begin{aligned}
\overline{B_{0}} & =\left\{\overline{l \theta}=\overline{r \theta} \mid l=r \in B_{0}, \theta \text { a sort specialization }\right\} \\
\bar{R} & =\{\overline{l \theta} \rightarrow \overline{r \theta} \mid l \rightarrow r \in R, \theta \text { a sort specialization }\}
\end{aligned}
$$

Example 3. Consider the module LIST-MSET-NAT of our running example of Section 1 and the equation
(MS ; NL) ; L = MS ; (NL ; L)
that is added by the theory transformation of Section 5 below, thus eliminating the associativity axiom for ";". The sorts of the variables are MS: MSet, NL: NeList and L: List. Hence, the labeled version of this equation (considering the identity specialization) is

$$
\begin{aligned}
& \text { (MS ; MSet,NeList NL) } ;_{\text {NeList,List }} L= \\
& \text { MS ; MSet,List }(N L \quad \text { ineList,List } \text { ). }
\end{aligned}
$$

Thus, the various occurrences of the symbol ";" in the equation are explicitly disambiguated. Moreover, there are 24 specializations of this equation (including the identity), because the variables can be specialized in the following way:

$$
\begin{aligned}
& \text { MS to MSet, Nat } \\
& \text { NL to NeList, MSet, Nat } \\
& \quad \text { L to List, NeList, MSet, Nat }
\end{aligned}
$$

Hence, according to Definition 5, our equation is transformed into 24 labeled equations given by

$$
\begin{aligned}
& (\mathrm{MS} ; \mathrm{x}, \mathrm{y} \mathrm{NL}) ; \mathrm{y}, \mathrm{z} \mathrm{~L}=\mathrm{MS} ; \mathrm{x}, \mathrm{z}(\mathrm{NL} ; \mathrm{y}, \mathrm{z} \\
& \text { L) } \\
& \text { where } X \in\{\text { MSet, Nat }\}, Y \in\{\text { NeList, MSet, Nat }\} \text {, } \\
& Z \in\{\text { List, NeList, MSet, Nat }\} .
\end{aligned}
$$

As shown by Example 4 below, the theory transformation of Definition 5 is not a sound reflection (w.r.t. .). However, it can be extended to a theory transformation that is a sound reflection (w.r.t. .). This is detailed in the appendix of this report. Nevertheless, in this short version of the paper we use labeled versions of rewrite rules exclusively to derive a "sort-aware" recursive dependency relation (cf. Definition 8 below). For this purpose, it suffices to use the simpler theory transformation of Definition 5. Hence, for the sake of simplicity, we use only this transformation in the rest of this section.

Example 4. Consider the theory $\mathcal{E}=\left(\Sigma, B_{0}, R\right)$ of Example 1. The rules of $\overline{\mathcal{E}}=\left(\Sigma^{o s}, \overline{B_{0}}, \bar{R}\right)$ are

$$
\begin{aligned}
f_{\{B, B\}}(b, x) & \rightarrow f_{\{A, A\}}\left(s_{B}(b), s_{B}(b)\right) \\
f_{\{A, B\}}\left(b, s_{B}(x)\right) & \rightarrow f_{\{B, B\}}(b, x) \\
f_{\{A, B\}}(b, x) & \rightarrow f_{\{A, A\}}\left(s_{B}(b), s_{B}(b)\right) \\
f_{\{A, B\}}\left(b, s_{A}(x)\right) & \rightarrow f_{\{A, B\}}(b, x)
\end{aligned}
$$

In the unlabeled system, we have $s=f(b, f(b, b)) \rightarrow_{R} f(s(b), s(b))=t$, but after labeling the corresponding reduction is impossible: $\bar{s}=f_{\{B, B, B\}}\left(b_{\epsilon}, f_{\{B, B, B\}}\left(b_{\epsilon}, b_{\epsilon}\right)\right) \not \not_{\bar{R}} f_{\{A, A\}}\left(s_{B}(b), s_{B}(b)\right)=\bar{t}$.

Based on the notion of recursive dependency and the labeling of function symbols, we now define well-founded recursive OS theories modulo axioms. These well-founded recursive theories are guaranteed to be terminating and properties like confluence and sufficient completeness can be verified incrementally. Left-hand sides of equations in well-founded OS theories are linear patterns, or linear constructor terms with constructor right-hand sides in case constructors are not $B_{0}$-free ( $\Omega \subseteq \Sigma$ is $B_{0}$-free iff for each specialization $l \nu \rightarrow r \nu$ with $l \rightarrow r \in R, l \nu$ is not an $\Omega$-term).

Definition 6 (pattern). Let $\mathcal{E}=\left(\Sigma, B_{0}, E\right)$ be an OS theory where $\Sigma=\mathcal{D} \uplus \Omega$ is partitioned into defined function symbols and constructors. ${ }^{6} A$ term $t$ is a pattern if it is linear and every proper subterm is from $\mathcal{T}(\Omega, V)$.

In order to obtain termination of well-founded recursive theories, arguments of functions called recursively by other mutually recursively dependent functions have to decrease. For example, when considering a rewrite rule $f\left(s_{1}, s_{2}, s_{3}\right) \rightarrow C\left[f\left(t_{1}, t_{2}, t_{3}\right)\right]$ for some context $C$, we demand that the tuple $\left\langle s_{1}, s_{2}, s_{3}\right\rangle$ resp. the multiset $\left\{s_{1}, s_{2}, s_{3}\right\}$ is greater than $\left\langle t_{1}, t_{2}, t_{3}\right\rangle$ resp. $\left\{t_{1}, t_{2}, t_{3}\right\}$ w.r.t. some extension of the subterm ordering to tuples or multisets that preserves well-foundedness. Whether arguments of non-commutative functions are compared as tuples (thus using a lexicographic ordering lex) or multisets (thus using a multiset ordering mul or a more specialized version tup for $A C$ functions) is determined by a status function. This provides a maximum of flexibility, since arguments of different functions can be compared in different ways (unless the functions are mutually recursive). The idea of recursive calls to functions with smaller collections of arguments is formalized by the notion of argument decreasing rules, where all recursive function calls are to functions with smaller argument collections.

Definition 7 (decreasing rule). Let $\mathcal{E}=\left(\Sigma, B_{0}, R\right)$ be an OS theory where $B_{0}$ consists exclusively of $A C$ and $C$ axioms and let stat: $\Sigma \rightarrow\{l e x, m u l\}$ be a status function on $\Sigma$. Moreover, let $l \rightarrow r$ be a rule of $R$ and $g$ a function symbol such that root $(l)$ and $g$ are either both $A C$ or none of them is AC. We say that $l \rightarrow r$ is $g$-argument decreasing if $\operatorname{stat}(\operatorname{root}(l))=\operatorname{stat}(g)$ and for each subterm $\left.r\right|_{p}$ of $r$ with $\operatorname{root}\left(\left.r\right|_{p}\right)=g$ there are terms $l^{\prime}={B_{0}} l$ and $w^{\prime}=\left.{B_{0}} r\right|_{p}$ such that

$$
\left\{\left.l^{\prime \prime}\right|_{1}, \ldots,\left.l^{\prime \prime}\right|_{\operatorname{ar}\left(\operatorname{root}\left(l^{\prime \prime}\right)\right)}\right\} \triangleright^{t u p}\left\{\left.w^{\prime \prime}\right|_{1}, \ldots,\left.w^{\prime \prime}\right|_{\operatorname{ar}\left(\operatorname{root}\left(w^{\prime \prime}\right)\right)}\right\}
$$

if $\operatorname{root}\left(l^{\prime}\right), \operatorname{root}\left(w^{\prime}\right) \in \Sigma_{A C}$ where $l^{\prime \prime}=f l a t\left(l^{\prime}, \operatorname{root}\left(l^{\prime}\right)\right)$ and $w^{\prime \prime}=f l a t\left(w^{\prime}, \operatorname{root}\left(w^{\prime}\right)\right)^{7}$; and

$$
\left\{\left.l^{\prime}\right|_{1}, \ldots,\left.l^{\prime}\right|_{\operatorname{ar}\left(\operatorname{root}\left(l^{\prime}\right)\right)}\right\} \triangleright^{m u l}\left\{\left.w^{\prime}\right|_{1}, \ldots,\left.w^{\prime}\right|_{\left.\operatorname{ar}\left(\operatorname{root}\left(w^{\prime}\right)\right)\right)}\right\}
$$

[^3]if $\operatorname{root}\left(l^{\prime}\right), \operatorname{root}\left(w^{\prime}\right) \notin \Sigma_{A C}$ and stat $(\operatorname{root}(l))=\operatorname{mul} ;$ and
\[

$$
\begin{aligned}
& \left\langle\left. l^{\prime}\right|_{1}, \ldots,\left.l^{\prime}\right|_{\left.\operatorname{ar}\left(\operatorname{root}\left(l^{\prime}\right)\right)\right\rangle}\right\rangle \triangleright^{l e x}\left\langle\left. w^{\prime}\right|_{1}, \ldots,\left.w^{\prime}\right|_{\left.\operatorname{ar}\left(\operatorname{root}\left(w^{\prime}\right)\right)\right\rangle}\right\rangle \\
& \text { if } \operatorname{root}\left(l^{\prime}\right), \operatorname{root}\left(w^{\prime}\right) \notin \Sigma_{A C} \text { and } \operatorname{stat}(\operatorname{root}(l))=\text { lex. }
\end{aligned}
$$
\]

Note that the status function does not assign the tup extension of the subterm ordering to non$A C$ function symbols, as the mul extension is more general and thus subsumes the use of the tup extension. For $A C$ function symbols it is crucial to compare multisets of arguments by $\triangleright^{t u p}$ instead of $\triangleright^{m u l}$ in order to obtain a well-founded decrease of argument multisets. Example 5 shows that theories may be non-terminating even if multisets of mutually recursive functions decrease w.r.t $\triangleright^{m u l}$.

Example 5. Consider the unsorted theory $\mathcal{E}$ (already used in Section 1) using a defined binary $A C$-function symbol $f$, a binary constructor $g$ and a constructor constant $a$. The single rule is $f(g(x, y), a) \rightarrow g(f(x, y), g(a, a))$.

We have $f \boldsymbol{\varepsilon} g$ but not $g \boldsymbol{\varepsilon} f$. Hence, we compare the arguments of $\operatorname{flat}(f(g(x, y), a), f)=$ $f(g(x, y), a)$ and $\operatorname{flat}(f(x, y), f)=f(x, y)$. We have $\{g(x, y), a\} \triangleright^{m u l}\{x, y\}$.

Indeed, $\mathcal{E}$ is not $A C$-terminating:

$$
\begin{array}{r}
f(g(f(a, a), g(a, a)), a)
\end{array} \rightarrow
$$

Note however that $\{g(x, y), a\} \not \diamond^{t u p}\{x, y\}$.
Now we are ready to define well-founded recursive OS theories modulo axioms. Ultimately, our goal is to show that well-founded recursive OS theories are compatible with a recursive path ordering that is compatible with $C$ and $A C$ axioms (i.e. an $A C R P O$ ). Due of the presence of rules like $c(c(x, y), z) \rightarrow c(x, c(y, z))$ (cf. e.g. Example 9 and Section 5 below) and commutative function symbols, it is crucial to compare arguments of some functions lexicographically and others by multiset orders. Moreover, for rules involving subsort-overloaded $A C$ function symbols, sorts may or may not be crucial and it may even be advantageous to ignore sorts of certain function symbols (cf. Example 6 below). Hence, the notion of well-founded recursive OS theory modulo axioms is parameterized by two status functions stat and stat ${ }_{a c}$. Note, however, that this does not compromise the syntactic and easy-to-check character of well-founded recursion, since the possible choices for these status functions are finite for each finite OS theory. However, finding working status functions may be computationally hard. To solve this problem we show in Section 4 below that these status functions can be computed incrementally when checking hierarchies of ordersorted theories for being well-founded recursive. Hence, provided that the theory extensions in such a hierarchy are small, the task of choosing suitable status functions is feasible.

Definition 8 (well-founded theories). Let $\mathcal{E}=\left(\Sigma, B_{0}, R\right)$ be an OS theory with constructors $\Omega \subseteq \Sigma$ where the structural axioms $B_{0}$ are either $A C$ or $C$ axioms. Let stat: $\Sigma \rightarrow\{$ lex, mul $\}$ be a status function where stat $(f)=$ mul for all $f \in \Sigma_{C} \cup \Sigma_{A C}$ and where $f \mathcal{E} g, g \boldsymbol{E} f$ implies $\operatorname{stat}(f)=\operatorname{stat}(g)$ and. Let stat ${ }_{a c}: \Sigma_{A C} \rightarrow\{s, u s\}^{8}$ be a status function where $f, g \in \Sigma_{A C}$ and $f \boxtimes_{\mathcal{E}} g, g \boxtimes_{\mathcal{E}} f$ implies stat ${ }_{a c}(f)=\operatorname{stat}_{a c}(g)$.
$\mathcal{E}$ is well-founded recursive iff (i) $g \vee_{\mathcal{E}} h$ and $h \boldsymbol{E} g(h, g \in \Sigma)$ implies that $h$ and $g$ are either both $A C$ symbols or both non-AC-symbols, and (ii) there are status function stat and stat ${ }_{a c}$ such that for each rule $l \rightarrow r$ and each specialization $\theta$ the following properties hold:

1. Either $l$ is a linear constructor term, or if not then $l$ is a pattern in case $\operatorname{root}(l) \in \Sigma \backslash \Sigma_{A C}$ and $f l a t(l, \operatorname{root}(l))$ is a pattern in case $\operatorname{root}(l) \in \Sigma_{A C}$.

[^4]2. If $l$ is a constructor term, then so is $r$.
3. For every (not necessarily proper) subterm $\left.r\right|_{p}$ of $r$,
$$
\operatorname{root}\left(\left.\overline{r \theta}\right|_{p}\right){ }_{\overline{\mathcal{E}}} \operatorname{root}(\overline{l \bar{\theta}})
$$
(resp. $\operatorname{root}\left(\left.r\right|_{p}\right) \wedge_{\mathcal{E}} \operatorname{root}(l) \in \Sigma_{A C}$ and stat $\left.a_{a c}=u s\right)$ implies that
$$
\overline{l \theta} \rightarrow \overline{r \theta} \text { is } \operatorname{root}\left(\left.\overline{r \theta}\right|_{p}\right) \text { argument decreasing (w.r.t. stat) }
$$
(resp. that $l \rightarrow r$ is $\operatorname{root}\left(\left.r\right|_{p}\right)$ argument decreasing).
4. Assume $\operatorname{root}(l)=\operatorname{root}\left(\left.r\right|_{p}\right)$ for some $p \in \operatorname{Pos}(r), \operatorname{root}\left(\left.r\right|_{p}\right) \boldsymbol{E}^{\operatorname{root}(l) \text { and } \operatorname{stat}} \operatorname{arc}_{\text {ac }}(\operatorname{root}(l))=s$ and consider the multiset $S$ of arguments of $\operatorname{root}(\overline{l \theta})$ in the term $\overline{l \theta}$ as well as the multiset $T$ of arguments of $\operatorname{root}\left(\overline{\left.\right|_{p} \theta}\right)$ in the term $\overline{\left.\right|_{p} \theta}$. For every variable $x \in T \backslash S$, there exists a term $s \in S \backslash T$, such that $l s(s)>l s(x)$. Moreover, $l a b(\operatorname{root}(\overline{l \theta})) \geq{ }^{\text {mul }} l a b\left(\operatorname{root}\left(\overline{\left.r\right|_{p} \theta}\right)\right)$.
5. If $l$ is a constructor term and root $(l)$ is associative and commutative, then
$$
\operatorname{root}\left(\left.f l a t(l, \operatorname{root}(l))\right|_{p}\right) \not{ }_{\varepsilon} \operatorname{root}(l)
$$
for all positions $p \in \operatorname{Pos}_{\Sigma}(f l a t(l, \operatorname{root}(l)))$ with $p>\epsilon$.
The status function stat in Definition 8 determines whether arguments of function symbols are compared lexicographically or by multiset comparison. Mutually recursive function symbols must have the same status. Moreover, arguments of commutative function symbols may only be compared by multiset orders. Hence, the problem of finding suitable statuses for non-commutative functions is very similar to the problem of finding suitable statuses for functions when checking TRSs for RPOS compatibility for which efficient methods exist (cf. e.g. [28]). These methods can be used to determine the status function when checking theories for being well-founded recursive. The other status function stat ${ }_{a c}$ determines whether sorts are taken into account when comparing arguments of $A C$-function symbols. The reason why we make this distinction is that in the presence of $A C$ function symbols it is not always desirable to take sorts into account, because the labels of $A C$-function symbols appearing in equations may change through instantiations.

Example 6. Consider an OS theory containing two sorts $A, B$ with $A<B$, an $A C$ function symbol $g: B, B \rightarrow B$, two unary function $h: B \rightarrow B$ and $t: B \rightarrow A$ and a constant $a: B$. Consider a rule

$$
g(h(x), h(y)) \rightarrow g(x, y)
$$

We have

$$
\operatorname{root}(\overline{g(h(x), h(y))})=g_{\{B, B\}}
$$

and indeed $\operatorname{root}(\overline{g(h(x), h(y)) \sigma})=g_{\{B, B\}}$ for every substitution $\sigma$. On the other hand, we have e.g. $\operatorname{root}(\overline{g(x, y) \sigma})=g_{\{B, B, B\}}$ if $x \sigma=g(a, a), y \sigma=y$. Hence, when instantiating the rule, there may be an increase in the multiset of sorts of the root symbol of the right-hand side compared to that of the root symbol of the left-hand side of the rule. In this case it is preferable to consider labeled occurrences of $g$ as equal, since there is a decrease in the arguments of the recursive function call. We would have $\operatorname{stat}_{a c}(g)=u s$ in this case.

On the other hand, consider a rule

$$
g(a, a) \rightarrow g(h(a), h(a)) .
$$

We have

$$
\begin{aligned}
\operatorname{root}(\overline{g(a, a)}) & =g_{\{B, B\}} \\
\operatorname{root}(\overline{g(h(a), h(a))}) & =g_{\{A, A\}} .
\end{aligned}
$$

Thus, in order to orient this rule, e.g. by an $(A C) R P O$, it is preferable to consider the symbols $g_{\{B, B\}}$ and $g_{\{A, A\}}$ as different ones, so that $g_{\{B, B\}}$ can be larger in the precedence of function symbols than $g_{\{A, A\}}$. We would have $\operatorname{stat}_{a c}(g)=s$ in this case.

The concrete value of $s t a t_{a c}$ for $A C$ functions can be determined by checking a theory for possible increases in the multisets of sorts (w.r.t. the multiset extension of the subsort ordering) of the arguments in recursive calls to other (or the same) $A C$ functions. If there are no such increases stat ${ }_{a c}$ of the corresponding function should be set to $s$, otherwise it should be set to $u s$.

Example 7. Consider the functional Maude module NATURAL of the running example of Section 1. It contains an identity axiom so it is outside the scope of well-founded recursive theories. However, by the semantics-preserving theory transformation described in Section 5 below, we obtain the following module which, considered as an OS theory modulo $C$, is sort-decreasing and well-founded recursive.

```
fmod TR-NATURAL is pr TRUTH-VALUE .
    sort Nat .
    op O : -> Nat [ctor] .
    op s : Nat -> Nat [ctor] .
    op _+_ : Nat Nat -> Nat [comm] .
    ops even odd : Nat -> Bool .
    vars N M : Nat .
    eq N + O = N .
    eq s(N) + s(M) = s(s(N + M)).
    eq even(0) = true .
    eq odd(0) = false .
    eq odd(s(N)) = even(N).
    eq even(s(N)) = odd(N).
endfm
```

Note that, since there is only one sort in this module, there are no non-trivial sort specializations and thus the equations of the labeled theory are identical with those of the unlabeled one (modulo names of function symbols; cf. Definition 5). Moreover, there are no $A C$ axioms. Hence, the status function $s t a t_{a c}$ is irrelevant. Finally, the choice of the status function stat is completely arbitrary since the module is well-founded recursive w.r.t. every choice of the status function.

As for stat, mutually recursive $A C$ function symbols have to agree on $s t a t_{a c}$ in well-founded recursive OS theories. In the presence of $A C$ function symbols $f \in \Sigma$ with $\operatorname{stat}_{a c}(f)=s$ in a well-founded recursive OS theory $\mathcal{E}$, two additional complications, compared to non- $A C$ function symbols or those with a $s t a t_{a c}$ of $u s$, may arise, but, as we explain below, these two potential complications do not cause any problems.

First, since $\Sigma^{o s}$ is infinite, there might be infinite decreasing $\overline{\mathcal{E}}^{\text {chains that are not looping. }}$ However, by Item (4) of Definition 8 we have $\Psi>^{\text {mul }} \Psi^{\prime}$ whenever, $f_{\Psi} \overline{\mathcal{E}}^{g_{\Psi^{\prime}}}\left(f_{\Psi} \neq g_{\Psi^{\prime}}\right.$ and $f, g \in \Sigma_{A C}$ ) where $<$ is the (well-founded) subsort ordering. Hence, there are no infinite nonlooping ${ }_{\overline{\mathcal{E}}}$ chains.

The second potential complication is that the labeling is not-stable under substitutions as illustrated by Example 6. Item (4) of Definition 8 ensures that this stability is restored by ensuring that the sort of every variable occurring directly under an $A C$ function symbols in the (subterm of the) right-hand side in question is dominated by a larger sort in the left-hand side.

The key result of this section is that well-founded recursive sort-decreasing OS theories modulo axioms are terminating. Therefore, our notion of well-founded recursive OS-theories provides: (i) a new formal definition that extends to the order-sorted and modulo $C$ and $A C$ cases the intuitive notion of "specification of a set of well-founded recursive functions"; (ii) a machine-checkable way of ascertaining whether a specification is indeed well-founded recursive; and (iii) a proof that such specifications are always terminating. Furthermore, as shown in Section 4, the checking that a specification is well-founded recursive can be made in a modular and incremental way. In practice, of course, we will want our well-founded recursive specifications to be also confluent, and sufficiently complete with respect to their constructors. These extra properties can also be checked incrementally, as explained in Section 4.

Theorem 1. Let $\mathcal{E}=\left(\Sigma, B_{0}, R\right)$ be a sort-decreasing well-founded recursive $O S$ theory where the structural axioms $B_{0}$ are either $A C$ or $C$ axioms. Then $\mathcal{E}$ is $B_{0}$-terminating.

Note that the sort-decreasingness requirement is essential in Theorem 1, as shown by the following example.

Example 8. Consider the following OS theory $\mathcal{E}$ without structural axioms. We have sorts $s_{1}$ and $s_{2}$ where $s_{1}<s_{2}$. Moreover, there is a unary function symbol $f$ typed $f: s_{2} \rightarrow s_{2}$, another unary function symbol $g$ typed $g: s_{2} \rightarrow s_{1}$ and a constant $a$ of sort $s_{2}$. The rules are

$$
\begin{aligned}
& f(a) \rightarrow f(g(a)), \\
& g(x) \rightarrow x
\end{aligned}
$$

where $x$ is a variable of sort $s_{2}$. This theory is well-founded recursive. For the problematic first rule we have

$$
\overline{f(a)}=f_{s_{2}}\left(a_{\epsilon}\right)
$$

and

$$
\overline{f(g(a))}=f_{s_{1}}\left(g_{s_{2}}\left(a_{\epsilon}\right)\right)
$$

Moreover, $f_{s_{1}} \not \overline{\mathcal{E}} f_{s_{2}}$ and $g_{s_{2}} f_{s_{2}}$.
However the theory is non-terminating as is witnessed by the cyclic reduction sequence

$$
f(a) \rightarrow f(g(a)) \rightarrow f(a)
$$

The problem here is that $\mathcal{E}$ is not sort-decreasing, since $l s(g(x))=s_{1} \nsupseteq s_{2}=l s(x)$ for the second rule if $x$ is of sort $s_{2}$.

### 3.1 Many-Sorted Well-Founded Functions as a Special Case of Well-Founded Theories

To further explain the generality of our notion of well-founded recursive theories we show in detail how it captures as a special case a very general notion of well-founded recursive definition in the many-sorted case without axioms. In a sense this is the most general comparison we can make with previous notions, since to the best of our knowledge the notion has not been previously studied in the order-sorted and modulo cases.

To simplify the exposition we focus on the case of recursive definitions without mutual recursion. It is well-known that by adding extra data constructors, such as product types, several mutually recursive functions can be expressed as a single function.

Definition 9. Let $\Omega$ be a many sorted signature of constructors. $A$ well-founded recursive tower is a sequence

$$
\left(f_{1}: s_{1}^{1} \ldots s_{n_{1}}^{1} \rightarrow s_{1}, R_{f_{1}}\right) \ldots\left(f_{m}: s_{1}^{m} \ldots s_{n_{m}}^{m} \rightarrow s_{m}, R_{f_{m}}\right)
$$

consisting of fresh function symbols $f_{1}, \ldots, f_{m}$ not in $\Omega$ and of sets of rules $R_{f_{i}}, 1 \leq i \leq m$, defining each $f_{i}$ such that the rules in $R_{f_{i}}$ are of the form

$$
f_{i}\left(t_{1}, \ldots, t_{n_{i}}\right) \rightarrow C\left[f_{i}\left(u_{1}^{1}, \ldots, u_{n_{i}}^{1}\right) \ldots f_{i}\left(u_{1}^{k}, \ldots, u_{n_{i}}^{k}\right)\right]
$$

with $t_{1}, \ldots, t_{n_{i}} \Omega$-terms and where:
(i) $f_{i}\left(t_{1}, \ldots, t_{n_{i}}\right)$ is linear and the right-hand side of the rule involves only variables occurring in $f\left(t_{1}, \ldots, t_{n_{i}}\right)$.
(ii) The context $C$ is a term in the signature $\Omega \cup\left\{f_{1}, \ldots, f_{i-1}\right\}$.
(iii) $k \geq 0$, and for each $1 \leq j \leq k$ the set $\left\{1, \ldots, n_{i}\right\}$ can be split into two disjoint subsets $A \uplus B=\left\{1, \ldots, n_{i}\right\}$ such that $1 \in A$, and
(1) for each $a \in A, t_{a} \unrhd u_{a}^{j}$;
(2) for each $b \in B$, either

* $u_{b}^{j} \in \mathcal{T}\left(\Omega \cup\left\{f_{1}, \ldots, f_{i-1}\right\}, \mathcal{X}\right)$, or
$* u_{b}^{j}=f_{i}\left(v_{1}^{b}, \ldots, v_{n_{i}}^{b}\right)$ with $\left(t_{1}, \ldots, t_{n_{i}}\right) \bowtie\left(v_{1}^{b}, \ldots v_{n_{i}}^{b}\right) ;$ and
(3) there is an $a \in A$ with $a<\min (B)$ such that $\left(t_{1}, \ldots, t_{a}\right) \triangleright\left(u_{1}^{j}, \ldots, u_{a}^{j}\right)$
where by definition $\left(t_{1}, \ldots, t_{l}\right) \triangleright\left(t_{1}^{\prime}, \ldots, t_{l}^{\prime}\right)$ iff for each $1 \leq i \leq l$, $t_{i} \unrhd t_{i}^{\prime}$, and there is a $j \in\{1, \ldots, l\}$ such that $t_{j} \triangleright t_{j}^{\prime}$.

Note that this definition includes as a special case all primitive recursive functions, where the terms $f_{i}\left(u_{1}^{j}, \ldots, u_{n_{i}}^{j}\right)$ are such that $\left(t_{1}, \ldots, t_{n_{i}}\right) \bowtie\left(u_{1}^{j}, \ldots, u_{n_{i}}^{j}\right)$. Note also that the equations for Ackerman's function in the introduction are a special instance of the above definition. In practice, two more conditions are required of such recursive towers:
(1) disjoint patterns, that is, if $f_{i}\left(t_{1}, \ldots, t_{n_{i}}\right)$ and $f_{i}\left(t_{1}^{\prime}, \ldots, t_{n_{i}}^{\prime}\right)$ are two different left-hand sides in $R_{f_{i}}$, which we may assume have distinct variables, then the patterns do not unify.
(2) sufficient completeness, that is, the collection of patterns

$$
\left\{\left(t_{1}, \ldots, t_{n_{i}}\right) \mid \exists t^{\prime} \text { s.t. } f_{i}\left(t_{1}, \ldots, t_{n_{i}}\right)=t^{\prime} \in R_{f_{i}}\right\}
$$

cover the product sort $s_{1}^{i} \times \ldots \times s_{n_{i}}^{i}$, in the sense that any ground term in that product is an instance of one of the patterns.

Those are precisely the conditions of confluence and sufficient completeness that we show how to check incrementally in Section 4. The main result is now:

Theorem 2. For any well-founded recursive tower as in Definition 9, the equational theory $(\Omega \cup$ $\left.\left\{f_{1}, \ldots, f_{m}\right\}, R_{f_{1}} \cup \ldots \cup R_{f_{m}}\right)$ is a well-founded recursive many-sorted theory.

## 4 Verifying Properties of OS Theories Incrementally

For well-founded recursive OS theories modulo axioms we can check important properties like termination, confluence, sort-decreasingness and sufficient completeness incrementally in the presence of theory hierarchies that satisfy reasonable conditions. These conditions are formalized in the notion of fair extension. The basic idea of fair extensions is that extending modules do not interfere with their base modules, i.e., they do not introduce new constructors of sorts of the base module and they do not redefine existing functions.

Definition 10 (fair extension). Assume that $\mathcal{E}_{1}=\left(\Sigma_{1}, B_{0}^{1}, R_{1}\right)$ and $\mathcal{E}_{2}=\left(\Sigma_{1} \cup \Sigma_{2}, B_{0}^{1} \cup B_{0}^{2}, R_{1} \cup\right.$ $R_{2}$ ) are $O S$ theories where the $B_{0}^{i} s$ are $C$ or $A C$ axioms for $i \in\{1,2\} . \Sigma_{1}$ and $\Sigma_{1} \cup \Sigma_{2}$ are order-sorted signatures. We write $\Sigma_{1}=\left(S_{1},<_{1}, F_{1}\right)$ and $\Sigma_{1} \cup \Sigma_{2}=\left(S_{1} \cup S_{2},<_{1} \cup<_{2}, F_{1} \cup F_{2}\right)$. Furthermore, $F_{i}$ is divided into constructors $\Omega_{i}$ and defined function symbols $\mathcal{D}_{i}$ for both $i \in\{1,2\}$. $\mathcal{E}_{2}$ is a fair extension of $\mathcal{E}_{1}$ iff:

1. every function symbol $f$ from $\Sigma_{1}$ is $A C$ (resp. C) in $\mathcal{E}_{2}$ iff it is $A C$ (resp. C) in $\mathcal{E}_{1}$;
2. $\Sigma_{2}$ does not introduce subsorts of sorts of $\Sigma_{1}$, i.e. $s \in S_{1} \wedge s^{\prime}<_{1} \cup<_{2}$ s for some $s^{\prime} \in S_{1} \cup S_{2}$ implies $s^{\prime}<_{1} s$;
3. $\Sigma_{2}$ does not contain new constructors of some sort of $S_{1}$, i.e. $f: s_{1}, \ldots, s_{n} \rightarrow s \in \Omega_{2}$ implies $s \notin S_{1}$;
4. for every rule $l \rightarrow r \in R_{2}$ and every function symbol $f: s_{1}, \ldots, s_{n} \rightarrow s \in F_{1}, l$ and the term $f\left(x_{s_{1}}^{1}, \ldots, x_{s_{n}}^{n}\right)$ do not unify in an order-sorted fashion modulo axioms (where $x_{s}$ denotes a variable of sort s).
5. if $f$ is a defined $A C$ symbol in $\mathcal{E}_{1}$ and $f \mathcal{E}_{1} g, g \mathcal{E}_{1} f$, then $g \mathcal{E}_{2} f$.
6. if $c \in \Omega_{1}$ and there is a rule $l \rightarrow r$ from $R_{1}$ such that root $(l)=c$, then $l$ does not overlap (order-sorted modulo axioms) with the left-hand side of any rule $l^{\prime} \rightarrow r^{\prime}$ of $R_{2}$ in case $\operatorname{root}\left(l^{\prime}\right)$ is a defined symbol in $\Sigma_{1} \cup \Sigma_{2}$, and $c$ does not occur below the root of $l^{\prime}$ in case $\operatorname{root}\left(l^{\prime}\right)$ is an associative-commutative constructor.

The first item of Definition 10 ensures that overloaded function symbols have the same set of attached axioms. Items $2-4$ ensure that no new subsorts and constructors of sorts of the base module are introduced and no functions of the base module are redefined. Item 5 makes sure that no additional mutual recursive dependency of $A C$ symbols is introduced by the extending module, and item 6 is needed to prevent overlaps of rules from $R_{1}$ that have constructor terms as left-hand sides with rules from $R_{2}$.

In the rest of this section we denote by $\mathcal{E}_{1}=\left(\Sigma_{1}, B_{0}^{1}, R_{1}\right)$ an OS theory modulo axioms $B_{0}^{1}$ and by $\mathcal{E}_{2}=\left(\Sigma_{1} \cup \Sigma_{2}, B_{0}^{1} \cup B_{0}^{2}, R_{1} \cup R_{2}\right)$ a fair extension of $\mathcal{E}_{1}$. By $\mathcal{E}_{2}^{\prime}$ we denote the OS theory $\left(\Sigma_{1} \cup \Sigma_{2}, B_{0}^{1} \cup B_{0}^{2}, R_{2}\right)$. First, we show modularity of sort-decreasingness. Then we show that the property of being well-founded recursive itself is modular, provided that the base and extending theory agree on the status functions.

Theorem 3 (modularity of sort-decreasingness). If $\mathcal{E}_{1}$ and $\mathcal{E}_{2}^{\prime}$ are both sort-decreasing, then so is $\mathcal{E}_{2}$.

Theorem 4 (modularity of well-founded recursion). If $\mathcal{E}_{1}$ and $\mathcal{E}_{2}^{\prime}$ are well-founded recursive w.r.t. to compatible functions stat ${ }^{1}$, stat ${ }_{a c}^{1}$ and stat ${ }^{2}$, stat ${ }_{a c}^{2}$, then so is $\mathcal{E}_{2}{ }^{9}$.

Note that we require that the status functions of the base theory and the extending theory are compatible. In a naive mechanization of incremental checks for well-founded recursiveness this could necessitate backtracking, i.e., modifying the status function of a base module depending on an extending theory. To avoid this backtracking, we propose to compute the status functions incrementally in a "by need" fashion. This means that a specific status is assigned to a function symbol (resp. an $A C$ symbol) only if this status is crucial for the theory in question to be well-founded recursive. Otherwise, the status is left open, so that it can be set later when incrementally checking an extending theory for well-founded recursiveness. For example, consider the theory of Example 7. It is well-founded recursive w.r.t. every status function stat. Hence, the status of functions can later be set arbitrarily when checking an extending module. A fully general implementation of this idea could, for example, compute a set of status functions for which a module is well-founded recursive. Then when checking an extending module for well-founded recursiveness one could choose suitable status functions from this set of possible ones. Next we show that confluence is modular for fair extensions of well-founded recursive theories.

Theorem 5 (modularity of confluence). Assume $\mathcal{E}_{1}$ and $\mathcal{E}_{2}^{\prime}$ are well-founded recursive w.r.t. to compatible functions stat ${ }^{1}$, stat ${ }_{a c}^{1}$ and stat ${ }^{2}$, stat ${ }_{a c}^{2}$. If $\mathcal{E}_{1}$ and $\mathcal{E}_{2}^{\prime}$ are confluent then so is $\mathcal{E}_{2}$.

Note that for sufficient completeness the adequate notion of modular check consists of checking the property only for new defined function symbols.

Theorem 6 (modularity of sufficient completeness). Assume $\mathcal{E}_{1}$ and $\mathcal{E}_{2}^{\prime}$ are well-founded recursive w.r.t. to compatible functions stat ${ }^{1}$, stat $t_{a c}^{1}$ and stat ${ }^{2}$, stat $t_{a c}^{2}$. If $\mathcal{E}_{1}$ is sufficiently complete and for every function $f: s_{1}, \ldots, s_{n} \rightarrow s \in \mathcal{D}_{2} \backslash \mathcal{D}_{1}$ and every ground substitution $\sigma$ mapping variables to irreducible constructor terms, $f\left(x_{s_{1}}^{1}, \ldots, x_{s_{n}}^{n}\right) \sigma$ is either $\mathcal{E}_{2}$-reducible or a constructor term ( $x_{s}$ denotes a variable of sort $s$ ), then $\mathcal{E}_{2}$ is sufficiently complete.

This way of incrementally checking sufficient completeness is compatible with existing automated methods to check the property. Roughly, the idea of these methods is to check whether ground terms rooted by a defined function symbol and having only constructor terms as proper subterms are either reducible, or constructor terms (which is possible as the root symbol might be subsort overloaded). This is done by describing the respective languages of terms by (propositional) tree automata and then reducing the problem to an emptiness problem for tree automata (we refer to [15] and [16] for more details). The method is suitable for incremental checks following Theorem 6 , since it can easily be adapted to consider only terms rooted by defined function symbols of the extending theory instead of all.

Corollary 1. Assume $\mathcal{E}_{1}$ and $\mathcal{E}_{2}^{\prime}$ are well-founded recursive w.r.t. to functions stat ${ }^{1}$, stat ${ }_{\text {ac }}^{1}$ and stat ${ }^{2}$, stat ${ }_{a c}^{2}$ that are compatible. If $\mathcal{E}_{1}$ and $\mathcal{E}_{2}^{\prime}$ are sort-decreasing and confluent and moreover, $\mathcal{E}_{1}$ is sufficiently complete and for every function $f: s_{1}, \ldots, s_{n} \rightarrow s \in \mathcal{D}_{2} \backslash \mathcal{D}_{1}$ and every irreducible ground substitution $\sigma$ (that maps variables only to constructor terms) $f\left(x_{s_{1}}^{1}, \ldots, x_{s_{n}}^{n}\right) \sigma$ is $\mathcal{E}_{2}$-reducible (or a constructor term), then $\mathcal{E}_{2}$ is sort-decreasing, well-founded recursive (thus terminating), confluent and sufficiently complete.

[^5]Example 9. Consider the running example of Section 1. In order to apply our methods to the modules of this example, the identity axioms and those axioms specifying associativity for a noncommutative function symbol have to be eliminated. Indeed, we can eliminate these problematic axioms by the theory transformation presented in Section 5. This transformation yields the module of Example 7 for the module NATURAL and the following two transformed theories for the modules MSET-NAT and LIST-MSAT-NAT.

```
fmod TR-MSET-NAT is pr TR-NATURAL .
    sort MSet .
    subsort Nat < MSet
    op _,_ : MSet MSet -> MSet [ctor assoc comm] .
    op null : -> MSet [ctor] .
    op card : MSet -> Nat .
    var MS : MSet .
    var N : Nat .
    var X : [MSet].
    eq X , null = X .
    eq card(null) = 0 .
    eq card(N) = s(0) + card(null) .
    eq card(N,MS) = s(0) + card(MS) .
endfm
fmod TR-LIST-MSET-NAT is pr TR-MSET-NAT .
    sorts List NeList .
    subsorts MSet < NeList < List .
    op nil : -> List [ctor] .
    op _;_ : List List -> List .
    op _;_ : MSet NeList -> NeList [ctor] .
    op U : List -> MSet .
    var MS : MSet .
    var NL : NeList .
    var L : List.
    var Y : [List].
    eq Y ; nil = Y .
    eq nil ; Y = Y .
    eq (MS ; NL) ; L = MS ; (NL ; L).
    eq U(nil) = null .
    eq U(MS) = MS .
    eq U(MS ; NL) = MS, U(NL).
endfm
```

We already established that the TR-NATURAL module is sort-decreasing and well-founded recursive in Example 7. Moreover, it is non-overlapping and thus (by termination) confluent. Sufficient completeness can automatically be verified by the Maude sufficient completeness checker (cf. e.g. [15]). The module TR-MSET-NAT, restricted to equations explicitly defined in the module and particularly not including the ones from the TR-NATURAL module, is sort-decreasing and well-founded recursive as well. This is seen for instance by using the status functions stat $(f)=m u l$ for all $f$ and $\operatorname{stat}_{a c}\left(\__{,},\right)=u s$. Confluence of the equations of TR-MSET-NAT follows again from nonoverlappingness. All ground instances of $\operatorname{card}(x)$ are reducible. Furthermore, TR-MSET-NAT is a fair extension of TR-NATURAL. Hence, it is sort-decreasing, well-founded recursive, confluent and sufficiently complete.

Finally, consider the module TR-LIST-MSET-NAT restricted to equations explicitly defined in the module and particularly not including the ones from the TR-MSET-NAT module. It is sortdecreasing and well-founded recursive (e.g. stat $(;)=l e x$ and $\operatorname{stat}(f)=m u l$ for all other functions $f)$. Furthermore, it is confluent because all critical pairs are joinable. All ground instances of $\left(x_{1} ; x_{2}\right)$ are either reducible or constructor terms and all ground instances of $U(x)$ are reducible. As TR-LIST-MSET-NAT is a fair extension of TR-MSET-NAT it is thus sort-decreasing, well-founded recursive (thus terminating), confluent and sufficiently complete.

## 5 A Variant-Based Theory Transformation

So far, our incremental methods for checking the sort-decreasingness, confluence, termination, and sufficient completeness of order-sorted well-founded recursive specifications modulo $B$ have been developed for the case where $B$ can only have commutativity and/or associativity-commutativity axioms. But we are interested in checking the confluence, termination, and sufficient completeness of more general order-sorted specifications $\mathcal{E}=(\Sigma, B, R)$ where $B$ can have any combination of associativity and/or commutativity and/or identity axioms (with some restrictions on the case of associativity without commutativity as explained below). The extension of our method to this more general case is accomplished by an automatic theory transformation $(\Sigma, B, R) \mapsto\left(\Sigma, B_{0}, \widehat{R} \cup \Delta\right)$ such that: (i) $B_{0}$ only involves commutativity and associativity-commutativity axioms; (ii) the theories $R \cup B$ and $B_{0} \cup \widehat{R} \cup \Delta$ are semantically equivalent (as inductive theories, see below); and (iii) $(\Sigma, B, R)$ is confluent, terminating, and sufficiently complete for $\Omega$ modulo $B$ iff ( $\Sigma, B_{0}, \widehat{R} \cup$ $\Delta$ ) has the same properties modulo $B_{0}$. Here we summarize and extend the basic ideas of the transformation and refer to [9] for further details.

The first key idea is to decompose $B$ as a disjoint union $B=B_{0} \cup \Delta$ so that $\left(\Sigma, B_{0}, \Delta\right)$ is confluent and terminating modulo $B_{0}$, and $\Delta$ contains all its $B_{0}$-extensions (cf. e.g. [26, Definition 10.4]). The second key idea is to generate the transformed rules $\widehat{R}$ by computing the most general $\Delta, B$-variants ([7]) of the left-hand sides $l$ for the rules $l \rightarrow r$ in $R$. Given a term $t$, a $\Delta, B$-variant of $t$ is a $\Delta, B$-canonical form $u$ of an instance of $t$ by some substitution $\theta$; more precisely, it is a pair $(u, \theta)$. Some variants are more general than others, so that variants form a preorder in a natural way. The set $\widehat{R}$ then consists of all rules $\widehat{l} \rightarrow r \theta$ such that $(\widehat{l}, \theta)$ is a maximal variant of $l$ for $l \rightarrow r$ a rule in $R$. Our transformation $(\Sigma, B, R) \mapsto\left(\Sigma, B_{0}, \widehat{R} \cup \Delta\right)$ is actually the composition of two simpler transformations of this kind:

$$
(\Sigma, B, R) \mapsto\left(\Sigma, B_{1}, \widehat{R}_{1} \cup \Delta_{1}\right) \mapsto\left(\Sigma, B_{0}, \widehat{R} \cup \Delta\right)
$$

where $B_{1}$ is obtained by removing all identity axioms ${ }^{10} \Delta_{1}$ from $B$, and $B_{0}$ is obtained by removing from $B_{1}$ all axioms that are associative but not commutative, so that $\Delta$ is the union of $\Delta_{1}$ and such associativity axioms oriented (in one of the two directions) as rules. In this way, $B_{0}$ only contains commutativity and/or associativity-commutativity axioms. We then incrementally check the confluence, termination, and sufficient completeness of $(\Sigma, B, R)$ modulo $B$ by checking the same properties modulo $B_{0}$ for the semantically equivalent theory ( $\left.\Sigma, B_{0}, \widehat{R} \cup \Delta\right)$ according to the methods already developed in Sections 3 and 4.

For the first transformation $(\Sigma, B, R) \mapsto\left(\Sigma, B_{1}, \widehat{R}_{1} \cup \Delta_{1}\right)$ we are always guaranteed that the set of rules $\widehat{R}_{1}$ is finite if $R$ is (see [9]). However, for the second transformation ( $\Sigma, B_{1}, \widehat{R}_{1} \cup$ $\left.\Delta_{1}\right) \mapsto\left(\Sigma, B_{0}, \widehat{R} \cup \Delta\right)$, which removes associative but not commutative axioms from $B_{1}$, we cannot in general guarantee that $\left(\Sigma, B_{0}, \widehat{R} \cup \Delta\right)$ is a finite theory. However, the use of subsorts can make it often the case in practice that $\left(\Sigma, B_{0}, \widehat{R} \cup \Delta\right)$ is finite. We can illustrate this interesting phenomenon with our running example. The first transformation, removing identities, leaves the equation $\mathrm{U}(\mathrm{MS}$; $N L)=\mathrm{MS}, \mathrm{U}(\mathrm{NL})$ unchanged because, since NL has sort NeList, the identity rules for _ ; cannot be applied to any instance of MS ; NL. By orienting the associativity axiom as a rule ( $L$; $P$ ) ; $Q \rightarrow L$; ( $P$; Q), the only variant of the equation $U(M S$; NL) $=M S, U(N L)$ is itself, since the left-hand side of the associativity rule fails to have an order-sorted unifier with the subterm MS ; NL. Therefore, the second transformation also succeeds in our running example (for the resulting transformed modules see Examples 7 and 9).

For well-founded recursive specifications containing operators $f$ that are associative but not commutative (with or without identity) we need to impose some conditions on such $f$ and slightly modify the version in [9] of the second transformation $\left(\Sigma, B_{1}, \widehat{R}_{1} \cup \Delta_{1}\right) \mapsto\left(\Sigma, B_{0}, \widehat{R} \cup \Delta\right)$. There should be only one such operator per connected component, with only two overloadings, which must be

[^6]1. either of the form $f:$ List List $\rightarrow$ List, $f:$ Elt NeList $\rightarrow$ NeList $[$ ctor] , with Elt $<$ NeList $<$ List,
2. or of the form $f:$ List List $\rightarrow$ List, $f:$ NeList Elt $\rightarrow$ NeList [ctor], with Elt $<$ NeList $<$ List.

Moreover, there may be no other constructors of sort List or lower except those of sort Elt or lower. The names Elt, NeList, and List are immaterial and are only used to respectively suggest sorts for list elements, nonempty lists, and general lists. Furthermore, in order to make sure that the associativity equations introduced by the second transformation have constructor patterns below their top function symbol (so that the conditions in Section 3 apply to the transformed theory $\left(\Sigma, B_{0}, \widehat{R} \cup \Delta\right)$ ), instead of introducing an associativity rule

$$
f(f(L, P), Q) \rightarrow f(L, f(P, Q))
$$

for case (1) (resp. $f(L, f(P, Q)) \rightarrow f(f(L, P), Q))$ for case (2)) with $L, P, Q$ of sort List, we introduce a more restricted rule

$$
f(f(E, N L), Q) \rightarrow f(E, f(N L, Q))
$$

for case (1) (resp. $f(Q, f(N L, E)) \rightarrow f(f(Q, N L), E))$ for case (2)) with $E$ of sort $E l t, N L$ of sort NeList, and $Q$ of sort List. It is then easy to check that: (i) the left-hand sides of these more restricted rules have constructor patterns below and have no nontrivial overlaps with themselves; (ii) $f$ so defined is sufficiently complete; and (iii) the unrestricted associativity equations are inductive theorems of the specification based on the more restricted associativity equations; that is, with this modified second transformation the theories $\left(\Sigma, B_{1}, \widehat{R}_{1} \cup \Delta_{1}\right)$ and ( $\left.\Sigma, B_{0}, \widehat{R} \cup \Delta\right)$, although no longer equivalent as OS theories, are nevertheless inductively equivalent in the sense that their initial algebras $\mathcal{T}_{\Sigma, B_{1} \cup \widehat{R}_{1} \cup \Delta_{1}}$ and $\mathcal{T}_{\Sigma, B_{0} \cup \widehat{R} \cup \Delta}$ are isomorphic. Indeed, we have

Lemma 1. Under the above restrictions on the first typing of an associative operator $f$, the associativity equation $f(f(L, P), Q)=f(L, f(P, Q))$ is an inductive consequence of the restricted associativity equation

$$
f(f(E, N L), Q)=f(E, f(N L, Q))
$$

. Likewise, under the second typing the associativity equation $f(L, f(P, Q))=f(f(L, P), Q)$ is an inductive consequence of the restricted associativity equation

$$
f(Q, f(N L, E))=f(f(Q, N L), E))
$$

In practice these restrictions are not too strong, since we can automatically ensure typings (1) or (2) by introducing them through a parameterized module for lists. Furthermore, the restriction of having only one typing of type (1) or (2) per connected component for each associative $f$ can be relaxed to allow several such typings, provided that the corresponding sorts Elt $<$ NeList $<$ List and $E l t^{\prime}<$ NeList ${ }^{\prime}<$ List $^{\prime}$ involved in two different typings are incomparable.

Example 10. We use our running example to illustrate the two theory transformations

$$
(\Sigma, B, R) \mapsto\left(\Sigma, B_{1}, \widehat{R}_{1} \cup \Delta_{1}\right) \mapsto\left(\Sigma, B_{0}, \widehat{R} \cup \Delta\right)
$$

The first transformation, adding identity axioms as explicit equations and computing the variants of rules with respect to identities, gives us the modules:

```
fmod TR1-NATURAL is pr TRUTH-VALUE .
    sort Nat .
    op 0 : -> Nat [ctor] .
    op s : Nat -> Nat [ctor] .
    op _+_ : Nat Nat -> Nat [comm] .
    ops even odd : Nat -> Bool .
    vars N M : Nat .
    eq N + O = N.
```

```
eq s(N) + s(M) = s(s(N + M)).
eq even(0) = true .
eq odd(0) = false .
eq odd(s(N)) = even(N).
eq even(s(N)) = odd(N).
endfm
fmod TR1-MSET-NAT is pr TR1-NATURAL .
    sort MSet .
    subsort Nat < MSet .
    op _,_ : MSet MSet -> MSet [ctor assoc comm] .
    op null : -> MSet [ctor] .
    op card : MSet -> Nat .
    var MS : MSet .
    var N : Nat .
    var X : [MSet].
    eq X , null = X .
    eq card(null) = 0 .
    eq card(N)=s(0) + card(null).
    eq card(N,MS)=s(0) + card(MS).
endfm
fmod TR1-LIST-MSET-NAT is pr TR1-MSET-NAT .
    sorts List NeList .
    subsorts MSet < NeList < List .
    op nil : -> List [ctor].
    op _;_ : List List -> List [assoc] .
    op _;_ : MSet NeList -> NeList [ctor assoc] .
    op U : List -> MSet .
    var MS : MSet .
    var NL : NeList .
    var L : List.
    var Y : [List].
    eq Y ; nil = Y .
    eq nil ; Y = Y .
    eq U(nil) = null .
    eq U(MS) = MS .
    eq U(MS ; NL) = MS, U(NL).
endfm
```

The way the variants of an equation with respect to the identities modulo the C and AC axioms are computed can be illustrated by the equation $\operatorname{card}(\mathrm{N}, \mathrm{MS})=\mathrm{s}(0)+\operatorname{card}(\mathrm{MS})$ in the original module MSET-NAT. Since the variable MS could collapse by instantiating it to the identity element null, the equation's left-hand side has two most general variants: (i) itself, so that the original equation is kept, and (ii) the term $\operatorname{card}(N)$, leading to the new variant equation $\operatorname{card}(N)=s(0)+\operatorname{card}(n u l l)$ added to TR1-MSET-NAT. The result of the second stage of the theory transformation, denoted above as $\left(\Sigma, B_{1}, \widehat{R}_{1} \cup \Delta_{1}\right) \mapsto\left(\Sigma, B_{0}, \widehat{R} \cup \Delta\right)$, has already been described in detail in Examples 7 and 9 . Note that, since they do not involve associative but not commutative axioms, the modules TR1-NAT and TR1-MSET-NAT are not changed by the second transformation.

## 6 Related Work and Conclusions

Our work is related to modularity methods for confluence and/or termination of TRSs. A very good survey of the literature on such methods up to 2002 can be found in [24]. One key difference is that, to the best of our knowledge, such work does not address sorts and subsorts, nor (except for, e.g., $[23,19])$ rewriting modulo axioms. Another difference is that in some cases the modularity conditions imposed are quite strong, requiring for example disjointness, which is relatively rare in practical module hierarchies. Perhaps the earliest work most closely related to ours is the work on proper extensions of term rewriting systems of [24] (cf. also [8] and [27]). The basic idea behind
proper extensions is that calls to functions $f$ in right-hand sides of rewrite rules $l \rightarrow r$ where $\operatorname{root}(l)$ and $f$ are mutually recursive, do not involve defined function symbols from the base theory (or from the extending theory that recursively depend on functions from the base theory) in the arguments of the function call. Our notion of fair extensions of well-founded recursive theories is even more restrictive in this respect, since the arguments of calls to functions in right-hand sides have to be constructor terms if the function in question is mutually recursive with the root of the left-hand side of the rule. Note however, that the advantage of our more restrictive definition is not just its ability to deal with sorts and structural axioms, but also in our case general termination is modular instead of the weaker notion of $C_{\mathcal{E}}$-termination as for proper extensions.

Our work is also related to the hierarchical termination approach of Urbain and Marché ([29, $23]$ ), with their notion of hierarchical extension being similar to ours of fair extension. In some ways our notion is more general, since for us function symbols can appear in both a submodule and a supermodule, but of course our incremental conditions are in other ways stronger so as to ensure termination, whereas in $[29,23]$ a modular approach to dependency pairs is developed. Furthermore [23] covers the $A C$ case. There is also a rich body of related work on rewriting modulo axioms, e.g. $[17,26,18,2,22,31]$. For termination modulo, related papers include, e.g., $[12,23,9,1]$.

When using well-founded recursive OS theories and fair extensions to create hierarchies of theories, one can verify important properties such as sort-decreasingness, termination, confluence and sufficient completeness incrementally. Hence, at a practical level, when developing equational programs (such as functional modules in Maude), one can follow a programming discipline ensuring that modules are well-founded recursive and module extensions are fair extensions. Sticking to this programming discipline then guarantees that the verification complexity of the properties in question grows roughly linearly with the number of distinct modules. This is a significant improvement compared to existing methods used for the verification of, e.g., termination where experiments show that in practice the verification complexity grows rapidly with increasing size of theories (see also [29]).

Obvious future work includes the mechanization of all the incremental checks described above in a tool, experimentation with such a tool, and the extension of our results to conditional and context-sensitive theories, which are also supported in Maude. Moreover, recent developments in the termination analysis of rewrite systems modulo axioms (cf. e.g. [1]) might allow us to relax the conditions in the notion of well-founded recursion, thus making our approach more widely applicable.

## A Termination of Well-founded OS Theories modulo axioms

In order to prove termination of well-founded recursive OS theories, we transform them into unsorted theories by labeling function symbols as in Definition 4. However, just labeling the rules and axioms as in Definition 5 does not yield an unsorted theory that is non-terminating whenever the sorted theory is. Hence, we need some additional and modified rules. The basic idea of our transformation is to transform a finite OS theory into an infinite unsorted theory. The unsorted theory is infinite, because we explicitly instantiate rules by terms built by $A C$ symbols.

Definition $11\left(V a r_{f}\right) . \operatorname{Var}_{f}(t)$ is the set of those variables of that occur as immediate argument of some function symbol $f$ occurring in $t$. Formally, $\left.\operatorname{Var}_{f}(f(x, y))=\{x, y\}, \operatorname{Var}_{f}\left(t_{1}, x\right)\right)=\{x\} \cup$ $\operatorname{Var}_{f}\left(t_{1}\right)$ if $\left.t_{1} \notin V, \operatorname{Var}_{f}\left(x, t_{2}\right)\right)=\{x\} \cup \operatorname{Var}_{f}\left(t_{2}\right)$ if $t_{2} \notin V, \operatorname{Var}_{f}\left(f\left(t_{1}, t_{2}\right)\right)=\operatorname{Var}_{f}\left(t_{1}\right) \cup \operatorname{Var}_{f}\left(t_{2}\right)$ if $t_{1} \notin V$ and $t_{2} \notin V, \operatorname{Var}(f)(x)=\emptyset$ and $\operatorname{Var}_{f}\left(g\left(t_{1}, \ldots, t_{k}\right)\right)=\operatorname{Var}_{f}\left(t_{1}\right) \cup \ldots \cup \operatorname{Var}_{f}\left(t_{k}\right)$ if $g \neq f$.

Definition $12\left(\right.$ Inst $\left._{A C}\right)$. Let $\mathcal{E}=\left(\Sigma, B_{0}, R\right)$ be an $O S$ theory where $B_{0}$ are $A C$ or $C$ axioms. Then the set of instantiated rules Inst $_{A C}(l \rightarrow r)$ is given by

$$
\begin{gathered}
\left\{l \sigma \rightarrow r \sigma \mid x_{i} \sigma \in \mathcal{T}(\{f\}, V) \text { if } x_{i} \in \operatorname{Var}_{f}(l) \cup \operatorname{Var}_{f}(r)\right. \\
\text { and } \left.f \in \Sigma_{A C}, y \sigma=y \text { otherwise }\right\} .
\end{gathered}
$$

Based on this instantiation we present the theory transformation from OS theories modulo $A C$ and $C$ axioms to unsorted theories modulo $A C$ and $C$ axioms that is a sound reflection.

Definition 13 (transformation). Assume that $\mathcal{E}=\left(\Sigma, B_{0}, R\right)$ is an OS theory where the structural axioms $B_{0}$ are $A C$ or $C$ axioms. The unsorted theory $\widetilde{\mathcal{E}}$ is $\left(\Sigma^{o s}, \widetilde{B_{0}}, \widetilde{R}\right)$. $\widetilde{B_{0}}$ is given by ${\widetilde{B_{0}}}^{A C} \cup{\widetilde{B_{0}}}^{C}$ where

$$
\begin{aligned}
{\widetilde{B_{0}}}^{A C}= & \left\{f_{\Psi}\left(f_{\Psi}(x, y), z\right)=f_{\Psi}\left(x, f_{\Psi}(y, z)\right)\right. \\
& f_{\Psi}(x, y)=f_{\Psi}(y, x) \mid \\
& f: A B \rightarrow A \in \Sigma_{A C}, \Psi=\left\{s_{1}, \ldots, s_{n}\right\} \\
& \left.s_{i} \leq A \text { for all } 1 \leq i \leq n\right\}
\end{aligned}
$$

and

$$
\begin{aligned}
{\widetilde{B_{0}}}^{C}= & \left\{f_{[C, D]}(x, y)=f_{[C, D]}(y, x) \mid f: A B \rightarrow G \in \Sigma_{C}\right. \\
& C \leq A, D \leq B\}
\end{aligned}
$$

$\widetilde{R}$ is given by $\widetilde{R}_{R} \cup \widetilde{R}_{j}{ }^{11}$ where $\widetilde{R}_{R}$ is

$$
\begin{aligned}
\left\{\overline{l^{\prime} \theta} \rightarrow \overline{r^{\prime} \theta} \mid\right. & l \rightarrow r \in R, \theta \text { a specialization, } \\
& \rightarrow r^{\prime} \in \operatorname{Inst}_{A C}(f(l, x) \rightarrow f(r, x)), \\
& \left.x \notin \operatorname{Var}(l) \cup \operatorname{Var}(r), f \in \Sigma_{A C}\right\} \cup \\
\left\{\overline{l^{\prime} \theta} \rightarrow \overline{r^{\prime} \theta} \mid\right. & l \rightarrow r \in R, l^{\prime} \rightarrow r^{\prime} \in \operatorname{Inst}_{A C}(l \rightarrow r), \\
\theta & \text { a specialization }\} .
\end{aligned}
$$

[^7]and $\widetilde{R}_{j}$ is
\[

$$
\begin{aligned}
\{\overline{l \theta} \rightarrow \overline{r \theta} \mid & l \rightarrow r \in \text { Inst }_{A C}\left(f\left(x_{1}, x_{2}\right) \rightarrow f\left(x_{1}, x_{2}\right)\right), \\
& f \in \Sigma_{A C}, \theta \text { a specialization, } \operatorname{root}(\overline{l \theta})=f_{\Psi}, \\
& \left.\operatorname{root}(\overline{r \theta})=f_{\Psi^{\prime}}, \Psi>^{\text {mul }} \Psi^{\prime}\right\} \cup \\
\{\overline{l \theta} \rightarrow \overline{r \theta} \mid & f \in \Sigma_{C}, l=f(x, y), r=f(x, y), \\
& \theta \text { a specialization, } \operatorname{root}(\overline{l \theta})=f_{[A, B]}, \\
& \left.\operatorname{root}(\overline{r \theta})=f_{\left[A^{\prime}, B^{\prime}\right]},\left(A, B \gtrdot A^{\prime}, B^{\prime}\right)\right\} \cup \\
\{\overline{l \theta} \rightarrow \overline{r \theta} \mid & f \in \Sigma \backslash\left(\Sigma_{C} \cup \Sigma_{A C}\right), l=f\left(x_{1}, \ldots, x_{n}\right), \\
& r=f\left(x_{1}, \ldots, x_{n}\right), \theta \text { a specialization, } \\
& \operatorname{root}(\overline{l \theta})=f_{A_{1}, \ldots, A_{n}}, \operatorname{root}(\overline{r \theta})=f_{A_{1}^{\prime}, \ldots, A_{n}^{\prime}}, \\
& \left.\left(A_{1}, \ldots, A_{n} \gtrdot A_{1}^{\prime}, \ldots, A_{n}^{\prime}\right)\right\} .
\end{aligned}
$$
\]

Note that in the theory $\widetilde{\mathcal{E}}=\left(\Sigma^{o s}, \widetilde{B_{0}}, \widetilde{R}\right)$ obtained from $\mathcal{E}=(\Sigma, A, E), \Sigma^{o s}, \widetilde{B_{0}}$ as well as $\widetilde{R}$ are countably infinite in general if $\Sigma, B_{0}$ and $R$ are finite. The following lemma states the important fact that two $B_{0}$-equal terms are also $\widetilde{B_{0}}$-equal after they are labeled.

Lemma 2. Let $\mathcal{E}=\left(\Sigma, B_{0}, R\right)$ be an OS theory where the structural axioms $B_{0}$ are $A C$ or $C$ axioms. If $t=B_{B_{0}} t^{\prime}$, then $\bar{t}=\widetilde{B_{0}} \overline{t^{\prime}}$.

Proof. We prove the result by showing that $t={ }_{B_{0}} t^{\prime}$ implies $\bar{t}=\widetilde{B_{0}} \overline{t^{\prime}}$ if $t^{\prime}$ is obtained from $t$ by substituting an instance of one side of a single equation from $B_{0}$ by the corresponding instance of the other side. The general case follows by induction on the number of equality steps. We distinguish two cases, depending on whether the function symbol for which an equation is used is $C$ or $A C$. First, assume a commutativity equation is used say for $f$ and let $f \in \Sigma_{C}$. Let $t=$ $C\left[f\left(t_{1}, t_{2}\right)\right]$ and $t^{\prime}=C\left[f\left(t_{2}, t_{1}\right)\right] . \bar{t}=\bar{C}\left[f_{[A, B]}\left(\overline{t_{1}}, \overline{t_{2}}\right)\right]$ according to Definition 4 (where $l s\left(t_{1}\right)=A$ and $\left.l s\left(t_{2}\right)=B\right)$. According to Definition 13 there is an equation $f_{[A, B]}(x, y)=f_{[A, B]}(y, x) \in \widetilde{B_{0}}$. Hence, $\bar{t}=\widetilde{B_{0}} \bar{C}\left[f_{[A, B]}\left(\overline{t_{2}}, \overline{t_{1}}\right)\right]=\overline{t^{\prime}}$.

Second, assume that an axiom for an $A C$ symbol was used and the used equation was an associativity equation. Let $t=C\left[f\left(f\left(t_{1}, t_{2}\right), t_{3}\right)\right]_{p}$ and $t^{\prime}=C\left[f\left(t_{1}, f\left(t_{2}, t_{3}\right)\right)\right]_{p}$. We write $t$ as $C^{\prime}\left[f\left(t_{1}^{\prime}, t_{2}^{\prime}\right)\right]_{q}$ where $q \leq p, \operatorname{root}\left(\left.C\right|_{o}\right)=f$ for each $q \leq o \leq p$ and either $q=\epsilon$ or the function symbol right above $q$ is not an $f\left(\right.$ i.e. $\operatorname{root}\left(\left.C^{\prime}\right|_{q^{\prime}}\right) \neq f$ if $q=q^{\prime} . i$ and $i \in \mathbb{N}$ ). Then

$$
\begin{aligned}
\bar{t} & =\overline{C^{\prime}}\left[f_{\Psi}\left(\lambda\left(t_{1}^{\prime}, f, \Psi\right), \lambda\left(t_{2}^{\prime}, f, \Psi\right)\right)\right]_{q} \\
& =C^{\prime \prime}\left[f_{\Psi}\left(f_{\Psi}\left(\lambda\left(t_{1}, f, \Psi\right), \lambda\left(t_{2}, f, \Psi\right)\right), \lambda\left(t_{3}, f, \Psi\right)\right)\right]_{p}
\end{aligned}
$$

which is $\widetilde{B_{0}}$-equal to

$$
C^{\prime \prime}\left[f_{\Psi}\left(\lambda\left(t_{1}, f, \Psi\right), f_{\Psi}\left(\lambda\left(t_{2}, f, \Psi\right), \lambda\left(t_{3}, f, \Psi\right)\right)\right)\right]_{p}
$$

because there is an equation

$$
f_{\Psi}\left(f_{\Psi}(x, y), z\right)=f_{\Psi}\left(x, f_{\Psi}(y, z)\right) \in \widetilde{B_{0}}
$$

according to Definition 13. Finally, we have

$$
C^{\prime \prime}\left[f_{\Psi}\left(\lambda\left(t_{1}, f, \Psi\right), f_{\Psi}\left(\lambda\left(t_{2}, f, \Psi\right), \lambda\left(t_{3}, f, \Psi\right)\right)\right)\right]_{p}=\overline{t^{\prime}}
$$

because $\operatorname{flat}\left(\left.t\right|_{q}, f\right)=\operatorname{flat}\left(\left.t^{\prime}\right|_{q}, f\right)$.
The cases where an associativity axiom is applied in the other direction and where a commutativity axiom is applied to an $A C$ symbol are analogous.

Lemma 3. Let $\mathcal{E}=\left(\Sigma, B_{0}, R\right)$ be a sort-decreasing OS theory where the structural axioms $B_{0}$ are $A C$ or $C$ axioms. Let $s$ and $s[t]_{p}$ be terms of $\mathcal{T}(\Sigma, V)$, such that $l s\left(\left.s\right|_{p}\right) \geq l s(t)$ and either $p=\epsilon$ or $\operatorname{root}\left(\left.s\right|_{p^{\prime}}\right) \neq \operatorname{root}(t)$ where $p^{\prime}$ is given by $p=p^{\prime} . i$ for some $i \in \mathbb{N}$. Then, $\bar{s}[t]_{p} \rightarrow_{\widetilde{R} / \widetilde{B_{0}}}^{*} \overline{s[t]_{p}}$.

Proof. Note that since $\operatorname{root}\left(\left.s\right|_{p^{\prime}}\right) \neq \operatorname{root}(t)$ we have $\left.\overline{s[t]_{p}}\right|_{p}=\bar{t}(\mathrm{cf}$. Definition 4). Hence, what needs to be done to derive $\overline{s[t]_{p}}$ from $\bar{s}[t]_{p}$, is to modify the sort-labels of function symbols above (or potentially parallel to) $p$ in $\bar{s}[]_{p}$.

To prove the result we use induction on the number of positions $o<p$ for which either $\operatorname{root}\left(\left.s\right|_{0}\right)$ is not an $A C$ symbol or $\operatorname{root}\left(\left.s\right|_{o}\right) \neq \operatorname{root}\left(\left.s\right|_{o . i}\right)$ where $i \in \mathbb{N}$ is uniquely determined by o.i $\leq p .{ }^{12}$ If the number of these positions is 0 , then $p=\epsilon$ and we are done because $\left.\bar{s}[t]_{p}\right|_{p}=\bar{t}$. Otherwise, we distinguish two cases, depending on whether $\operatorname{root}(s)$ is an $A C$ symbol, or a $C$ or free symbol.

If it is a free or $C$ (but not $A C$ ) symbol, then we write $s[t]_{p}$ as $f\left(t_{1}, \ldots, s_{j}[t]_{q}, \ldots, t_{n}\right)$ where $j$ and $q$ are determined by $j . q=p$ and $j \in \mathbb{N}$. The induction hypothesis yields $\overline{s_{j}}[]_{q} \rightarrow_{\widetilde{R} / \widetilde{B_{0}}}^{*} \overline{s_{j}[t]_{q}}$. As $l s\left(\left.s\right|_{p}\right) \geq l s(t)$ and by monotonicity of $\Sigma$ we have $l s\left(s_{j}\right) \geq l s\left(s_{j}[t]_{q}\right)$. If $l s\left(s_{j}\right)=l s\left(s_{j}[t]_{q}\right)$, we have

$$
\left.\bar{s}[t]_{p}=\bar{s}\left[\overline{s_{j}}[t]_{q}\right]_{j} \xrightarrow{I H_{R} / \widetilde{B_{0}}} \bar{s} \overline{s_{j}[t]_{q}}\right]_{j}=\overline{s\left[s_{j}[t]_{q}\right]_{j}}=\overline{s[t]_{p}} .
$$

Otherwise, if $l s\left(s_{j}\right)>l s\left(s_{j}[t]_{q}\right)$, we have

$$
\begin{aligned}
& l s\left(\left.s\right|_{1}\right), \ldots, l s\left(\left.s\right|_{j}\right), \ldots, l s\left(\left.s\right|_{n}\right) \gtrdot \\
& \quad l s\left(\left.s\right|_{1}\right), \ldots, l s\left(\left.s\right|_{j}[t]_{q}\right), \ldots, l s\left(\left.s\right|_{n}\right)
\end{aligned}
$$

and thus there exists a rule

$$
\begin{aligned}
& f_{l s\left(\left.s\right|_{1}\right), \ldots, l s\left(\left.s\right|_{j}\right), \ldots, l s\left(\left.s\right|_{n}\right)}\left(x_{1}, \ldots, x_{n}\right) \rightarrow \\
& \quad f_{l s\left(\left.s\right|_{1}\right), \ldots, l s\left(\left.s\right|_{j}[t]_{q}\right), \ldots, l s\left(\left.s\right|_{n}\right)}\left(x_{1}, \ldots, x_{n}\right)
\end{aligned}
$$

in case $\operatorname{root}(s)$ is a free symbol, and a rule

$$
f_{\left[l s\left(\left.s\right|_{1}\right), l s\left(\left.s\right|_{2}\right)\right]}(x, y) \rightarrow f_{\left[l s\left(\left.s\right|_{1}[t]_{q}\right), l s\left(\left.s\right|_{2}\right)\right]}(x, y)
$$

in case $\operatorname{root}(s)$ is commutative (assuming w.l.o.g. that $j=1$ in this case) in $\widetilde{R}$ yielding

$$
\bar{s}[\bar{t}]_{p}=\bar{s}\left[\bar{s}_{j}[\bar{t}]_{q}\right]_{j} \xrightarrow{I H_{\widetilde{R} / / B_{0}}^{*}} \bar{s}\left[\overline{s_{j}[t]_{q}}\right]_{j} \rightarrow_{\widetilde{R}} \overline{s\left[s_{j}[t]_{q}\right]_{j}}=\overline{s[t]_{p}} .
$$

Next assume $\operatorname{root}(s)$ is an $A C$ symbol. We write

$$
s[t]_{p}=C\left[t_{1}, \ldots, t_{k}[t]_{q}, \ldots, t_{m}\right]_{p_{1}, \ldots, p_{k}, \ldots, p_{m}}
$$

where $C\left[x_{1}, \ldots, x_{m}\right]_{p_{1}, \ldots, p_{m}} \in \mathcal{T}(\{\operatorname{root}(s)\}, V), \underline{\operatorname{root}}\left(t_{i}\right) \neq \operatorname{root}(s)$ for all $1 \leq i \leq m$ and $p_{k} \cdot q=p$. The induction hypothesis yields $\overline{t_{k}}[]_{q} \rightarrow \stackrel{\widetilde{R} / \widetilde{B_{0}}}{*} \overline{t_{k}[t]_{q}}$. As $l s\left(\left.s\right|_{p}\right) \geq l s(t)$ and by monotonicity of $\Sigma$ we have $l s\left(t_{k}\right) \geq l s\left(t_{k}[t]_{q}\right)$. If $l s\left(t_{k}\right)=l s\left(t_{k}[t]_{q}\right)$, we have

$$
\bar{s}[t]_{p}=\bar{s}\left[t_{k}[t]_{q}\right]_{p_{k}} \xrightarrow{I H_{R}^{*}} \widetilde{R} / \widetilde{B_{0}} \bar{s}\left[\overline{t_{k}[t]_{q}}\right]_{p_{k}}=\overline{s\left[t_{k}[t]_{q}\right]_{p_{k}}}=\overline{s[t]_{p}}
$$

Otherwise, we have $\operatorname{flat}(s, \operatorname{root}(s))=\operatorname{root}(s)\left(t_{1}, \ldots, t_{m}\right)$ and $\operatorname{root}(\overline{\operatorname{flat}(s, \operatorname{root}(s))})=f_{\Psi}$ where

$$
\begin{aligned}
\Psi=\{ & \left\{s\left(t_{1}\right), \ldots, l s\left(t_{k}\right), \ldots, l s\left(t_{m}\right)\right\}>^{m u l} \\
& \left\{l s\left(t_{1}\right), \ldots, l s\left(t_{k}[t]_{q}\right), \ldots, l s\left(t_{m}\right)\right\}=\Psi^{\prime}
\end{aligned}
$$

and $\left.\operatorname{root}\left(\overline{\operatorname{flat}\left(s[t]_{p}\right.}, \operatorname{root}(s)\right)\right)=f_{\Psi^{\prime}}$. Thus, there is a rule in $\widetilde{R}$ that is a labeled version of

$$
C\left[x_{1}, \ldots, x_{m}\right] \rightarrow C\left[x_{1}, \ldots, x_{m}\right]
$$

such that the (single) function symbol $f$ occurring in the left-hand side is consistently labeled by $\Psi$ and the function symbol on the right-hand side is consistently labeled by $\Psi^{\prime}$. Hence, we obtain

$$
\bar{s}[\bar{t}]_{p}=\bar{s}\left[\overline{t_{k}}[\bar{t}]_{q}\right]_{p_{k}} \xrightarrow{I H^{R} / \widetilde{B_{0}}} \underset{ }{*}\left[\overline{t_{k}[t]_{q}}\right]_{p_{k}} \rightarrow_{\widetilde{R}} \overline{s\left[t_{k}[t]_{q}\right]_{p_{k}}}=\overline{s[t]_{p}}
$$

[^8]Lemma 4 (sound reflection property). Let $\mathcal{E}=\left(\Sigma, B_{0}, R\right)$ be a left-linear sort-decreasing OS theory where the structural axioms $B_{0}$ are $A C$ or $C$ axioms. If $s \rightarrow_{R / B_{0}}$ t, then $\bar{s} \rightarrow_{\widetilde{R} / \widetilde{B_{0}}}^{+} \bar{t}$.

Proof. We write $s \rightarrow_{R / B_{0}} t$ as $s={ }_{B_{0}} s^{\prime} \xrightarrow{p}_{R} t^{\prime}={ }_{B_{0}} t$. Then $\left.s^{\prime}\right|_{p}=l \sigma$ for some $l \rightarrow r \in R$ and some substitution $\sigma$. By Lemma 2 we have $\bar{s}=\widetilde{B_{0}} \overline{s^{\prime}}$. We distinguish two cases depending on whether the function symbol immediately above $p$ in $s^{\prime}$ (i.e. at position $p^{\prime}$ given by $p^{\prime} . i=p$ for some $i \in \mathbb{N}$ ) is an $A C$ symbol or not.

If this symbol is not an $A C$ symbol (or $p$ is the root position), then $\overline{s^{\prime}}=\overline{s^{\prime}}\left[\left.\bar{s}^{\prime}\right|_{p}\right]_{p}$. We inspect $\left.s^{\prime}\right|_{p}=l \sigma$ for some rule $l \rightarrow r \in R$. It can be written as $l \theta \sigma^{\prime}$, where $x \theta \in \mathcal{T}(\{f\}, V)$ whenever $x \in \operatorname{Var}_{f}(l) \cup \operatorname{Var}_{f}(r)$ and $f$ is an $A C$ symbol (cf. Definition 12) and $\operatorname{root}\left(x \sigma^{\prime}\right) \neq f$ whenever $x \in \operatorname{Var}_{f}(l \theta) \cup \operatorname{Var}_{f}(r)$. Then we have, $l \theta \rightarrow r \theta \in \operatorname{Inst}_{A C}(l \rightarrow r)$ by Definition 12. Moreover, $\overline{l \theta \sigma^{\prime}}=\overline{l \theta} \overline{\sigma^{\prime}}$. Let $\tau$ be a specialization for the variables of $l \theta$ given by $x: S \tau=x: S^{\prime}$ if $l s(x \sigma)=S^{\prime}$. Then, by Definition 13 , there is a rule $\overline{l \theta \tau} \rightarrow \overline{l \theta \tau} \in \widetilde{R}$. With this rule we have

$$
\begin{aligned}
& \overline{s^{\prime}}=\overline{s^{\prime}}\left[\overline{\left.s^{\prime}\right|_{p}}\right]_{p}=\overline{s^{\prime}}[\overline{l \sigma}]_{p}=\overline{s^{\prime}}\left[\overline{\left[\theta \sigma^{\prime}\right.}\right]_{p}= \\
& =\overline{s^{\prime}}\left[\overline{[\theta} \overline{\sigma^{\prime}}\right]_{p} \rightarrow_{\widetilde{R}} \overline{s^{\prime}}\left[\overline{r \theta} \overline{\sigma^{\prime}}\right]_{p}=\overline{s^{\prime}}\left[\overline{\left.t^{\prime}\right|_{p}}\right]_{p} .
\end{aligned}
$$

Now consider the case where the function symbol immediately above $p$ is an $A C$ symbol, say $f$. Then $s^{\prime}$ can be written as $s^{\prime}\left[\left.s^{\prime}\right|_{q}\right]_{q}$ where $q<p$, the function symbol at the position right above $q$ in $s^{\prime}$ is not $f$ (or $q=\epsilon$ ) and $\operatorname{root}\left(\left.s^{\prime}\right|_{o}=f\right.$ ) for all $q \leq o<p$. Then we have $\overline{s^{\prime}}=\overline{s^{\prime}}\left[\overline{\left.s^{\prime}\right|_{q}}\right]_{q}$. By associativity and commutativity of $f$ and Lemma 2, there is a term $\bar{w}=B_{B_{0}} \overline{\left.s^{\prime}\right|_{q}}$ such that $\operatorname{root}(\bar{w})=f$ and $\left.\bar{w}\right|_{1}=\overline{\left.s^{\prime}\right|_{p}}$. We can write $w$ (i.e. erase $\left.(\bar{w})\right)$ as $f(l, x) \theta \sigma^{\prime}$ where $l \theta \sigma^{\prime}=\left.s\right|_{p}, l \rightarrow r \in R, x \notin \operatorname{Var}(f)$, $y \theta \in \mathcal{T}(\{f\}, V)$ whenever $y \in \operatorname{Var}_{f}(f(l, x)) \cup \operatorname{Var}_{f}(f(r, x))$ and $\operatorname{root}\left(y \sigma^{\prime}\right) \neq f$ whenever $y \in$ $\operatorname{Var}_{f}(f(l, x) \theta) \cup \operatorname{Var}_{f}(f(r, x) \theta)$. Moreover, let $\tau$ be a specialization for the variables of $f(l, x) \theta$ given by $x: S \tau=x: S^{\prime}$ if $l s(x \sigma)=S^{\prime}$. Then, by Definition 13 , there is a rule $\overline{f(l, x) \theta \tau} \rightarrow \overline{f(r, x) \theta \tau} \in \widetilde{R}$. Thus, we have

$$
\begin{aligned}
& \overline{s^{\prime}}=\overline{s^{\prime}}\left[\overline{\left.s^{\prime}\right|_{q}}\right]_{q}=\widetilde{A} \bar{s}^{\prime}[\bar{w}]_{q}=\overline{s^{\prime}}\left[\overline{f(l, x) \theta \sigma^{\prime}}\right]_{q}= \\
& =\bar{s}\left[\overline{f(l, x) \theta} \overline{\sigma^{\prime}}\right]_{q} \rightarrow_{\widetilde{R}} \overline{s^{\prime}}\left[\overline{f(r, x) \theta} \overline{\sigma^{\prime}}\right]_{q}=\widetilde{B_{0}} \overline{s^{\prime}}\left[\overline{\left.t^{\prime}\right|_{q}}\right]_{q}
\end{aligned}
$$

Note that in the last equality we need to use $\widetilde{B_{0}}$ to inversely apply the axioms used to derive $w$ from $\left.s\right|_{q}$, which is possible e.g. by Lemma 2 . By sort decreasingness of $\mathcal{E}$ and monotonicity of $\Sigma$, we have $l s\left(\left.t^{\prime}\right|_{q}\right) \leq l s\left(\left.s^{\prime}\right|_{q}\right)$, hence Lemmas 3 and 2 yield $\overline{s^{\prime}}\left[\overline{\left.t^{\prime}\right|_{q}}\right]_{q} \rightarrow \widetilde{\widetilde{R} / \widetilde{B_{0}}} \underset{ }{*} \bar{t}$.

Corollary 2. Let $\mathcal{E}=\left(\Sigma, B_{0}, R\right)$ be a left-linear sort-decreasing $O S$ theory where the structural axioms $B_{0}$ are $A C$ or $C$ axioms. If $\widetilde{\mathcal{E}}$ is $\widetilde{B_{0}}$-terminating, then $\mathcal{E}$ is $B_{0}$-terminating.

Next we are going to prove that well-founded recursive OS theories are terminating, by showing that for a given well-founded recursive theory $\mathcal{E}, \widetilde{\mathcal{E}}$ is compatible with an $A C R P O$ as introduced by Kapur et. al. ([20]). Note that the presence of function symbols that are commutative but not associative is not a problem, since arguments of non associative function symbols are compared as multisets and hence terms $f(x, y)$ and $f(y, x)$ are always equivalent w.r.t. to an $A C R P O \succ_{a c}$.

First, we prove some general properties of an $A C R P O \succ_{a c}$, which are then used in Theorem 1 below. We show that if we have $s \triangleright t$ for two terms $s$ and $t$ of a particular shape, then for each pair $\langle a, b\rangle \in \operatorname{cands}(t, f)$ there is a pair $\left\langle a^{\prime}, b^{\prime}\right\rangle \in \operatorname{cands}(s, f)$ with $\left\langle a^{\prime}, b^{\prime}\right\rangle \succ_{c}\langle a, b\rangle$ (cf. [20][Definitions 12 and 17]). Note that this result is stronger than $\operatorname{cands}(s, f) \succ_{c}^{m u l} \operatorname{cands}(t, f)$ which is a consequence of Lemma 1 in Kapur et. al. ([20][Lemma 1]). In the following, whenever we mention an ACRPO $\succ_{a c}$ we mean $\succ_{a c}$ as defined in Definition 17 by Kapur et. al. ([20][Definition 17]).

Lemma 5. Let $\Sigma$ be an unsorted signature and let $\succ_{a c}$ be an ACRPO w.r.t. a precedence $>$ on function symbols. If $s \triangleright t$ for terms $s$ and $t$, where $\operatorname{root}\left(\left.s\right|_{p}\right)<f$ and $\operatorname{root}\left(\left.t\right|_{q}\right)<f$ for all $p \in \operatorname{Pos}_{\Sigma}(s)$ and all $q \in \operatorname{Pos}_{\Sigma}(t)$, then for each pair $\langle a, b\rangle \in \operatorname{cands}(t, f)$, there is a pair $\left\langle a^{\prime}, b^{\prime}\right\rangle \in$ cands $(s, f)$ such that $\left\langle a^{\prime}, b^{\prime}\right\rangle \succ_{c}\langle a, b\rangle$ (where $\succ_{c}$ is defined as in [20][Definition 17]).

Proof. If $s$ is a ground term, then $\operatorname{cands}(s, f)=\{\langle\{a\},\{\langle\{a\}, s\rangle\}\rangle\}$. In that case $t$ is a ground term as well and we have $\operatorname{cands}(t, f)=\{\langle\{a\},\{\langle\{a\}, t\rangle\}\rangle\}$. Hence, $\langle\{a\},\{\langle\{a\}, s\rangle\}\rangle \succ_{c}\langle\{a\},\{\langle\{a\}, t\rangle\}\rangle$ proves the result.

Otherwise, we have

$$
\operatorname{cands}(s, f)=\{\langle\{y\},\{\langle\{y\}, s\rangle\}\rangle \mid y \in \operatorname{Var}(s)\}
$$

where by $\operatorname{Var}(s)$ we mean the multiset of variables in $s$ and $\operatorname{cands}(s, f)$ is a multiset, too. We have three possibilities for $\operatorname{cands}(t, f)$ :

First,

$$
\operatorname{cands}(t, f)=\{\langle\{x\}, \emptyset\rangle\}
$$

if $t$ is the variable $x$. In that case there is a pair $\langle\{x\},\{\langle\{x\}, s\rangle\}\rangle$ in $\operatorname{cands}(s, f)$ and we have

$$
\langle\{x\},\{\langle\{x\}, s\rangle\}\rangle \succ_{c}\langle\{x\}, \emptyset\rangle
$$

(regardless of the used abstraction).
Second,

$$
\operatorname{cands}(t, f)=\{\langle\{a\},\{\langle\{a\}, t\rangle\}\rangle\}
$$

if $t$ is a ground term. In that case for every pair $\langle\{x\},\{\langle\{x\}, s\rangle\}\rangle \in \operatorname{cands}(s, f)$ we have

$$
\langle\{x\},\{\langle\{x\}, s\rangle\}\rangle \succ_{c}\langle\{a\},\{\langle\{a\}, t\rangle\}\rangle
$$

Finally, if $t$ is not a variable and not a ground term, we have

$$
\operatorname{cands}(t, f)=\{\langle\{y\},\{\langle\{y\}, t\rangle\}\rangle \mid y \in \operatorname{Var}(t)\}
$$

As $s \triangleright t, \operatorname{Var}(t) \subseteq \operatorname{Var}(s)$ and thus for every pair $\langle\{x\},\{\langle\{x\}, t\rangle\}\rangle \in \operatorname{cands}(t, f)$ there is a pair $\langle\{x\},\{\langle\{x\}, s\rangle\}\rangle \in \operatorname{cands}(s, f)$ such that we have

$$
\langle\{x\},\{\langle\{x\}, t\rangle\}\rangle \succ_{c}\langle\{x\},\{\langle\{x\}, s\rangle\}\rangle
$$

according to [20][Definition 17] (again regardless of the used abstraction; note that $s \triangleright t$ implies $s \succ_{a c} t$, since $\succ_{a c}$ is a simplification ordering).

The next lemma states a property about the extension $\succ^{\text {tup }}$ of an ordering $\succ$ defined in Definition 8.

Lemma 6. Let $S \succ^{\text {tup }} T$ for multisets $S, T$ and some ordering $\succ$ and function $\phi$. If $S=S^{\prime} \cup(S \cap T)$ and $T=T^{\prime} \cup(S \cap T)$ and $\phi\left(s^{\prime}\right)=t^{\prime}$ for $s^{\prime} \in S^{\prime}$ and $t^{\prime} \in T^{\prime}$, then $S \backslash\left\{s^{\prime}\right\} \succ^{\text {tup }} T \backslash\left\{t^{\prime}\right\}$ or $S \backslash\left\{s^{\prime}\right\}=T \backslash\left\{t^{\prime}\right\}$.

Proof. By the definition of $\succ^{t u p}$.
The following lemma is the technical key to finally proving $A C$-termination of rewrite derivations w.r.t. a well-founded OS theory.

Lemma 7. Let $\Sigma$ be an unsorted signature and $\succ_{a c}$ be an $A C R P O$ on $\mathcal{T}(\Sigma, V)$ where $<$ is the used precedence. Moreover, let

$$
\begin{aligned}
& \operatorname{Cands}_{1}=\left\{\left\langle c_{1} \cup \ldots \cup c_{n}, p_{1} \cup \ldots \cup p_{n}\right\rangle \mid\right. \\
& \left.\quad\left\langle c_{1}, p_{1}\right\rangle \in \operatorname{cands}\left(s_{1}, f\right), \ldots,\left\langle c_{n}, p_{n}\right\rangle \in \operatorname{cands}\left(s_{n}, f\right)\right\}
\end{aligned}
$$

and

$$
\begin{aligned}
& \text { Cands }_{2}=\left\{\left\langle c_{1}^{\prime} \cup \ldots \cup c_{m}^{\prime}, p_{1}^{\prime} \cup \ldots \cup p_{m}^{\prime}\right\rangle \mid\right. \\
& \left.\quad\left\langle c_{1}^{\prime}, p_{1}^{\prime}\right\rangle \in \operatorname{cands}\left(t_{1}, f\right), \ldots,\left\langle c_{m}^{\prime}, p_{m}^{\prime}\right\rangle \in \operatorname{cands}\left(t_{m}, f\right)\right\}
\end{aligned}
$$

for multisets $\left\{s_{1}, \ldots, s_{n}\right\}$ and $\left\{t_{1}, \ldots, t_{m}\right\}$ of terms from $\mathcal{T}\left(\Sigma^{<f}, V\right)$ each having pairwise disjoint variables and satisfying $\left\{s_{1}, \ldots, s_{n}\right\} \triangleright^{t u p}\left\{t_{1}, \ldots, t_{m}\right\} .{ }^{13}$ Then Cands $\succ_{c} \succ_{c}^{m u l}$ Cands $s_{2}$.

[^9]Proof. $\left\{s_{1}, \ldots, s_{n}\right\} \triangleright^{t u p}\left\{t_{1}, \ldots, t_{m}\right\}$ means that

$$
\begin{aligned}
& \left\{s_{1}, \ldots, s_{n}\right\}=\left\{s_{i_{1}}, \ldots, s_{i_{n^{\prime}}}\right\} \cup \Pi \\
& \left\{t_{1}, \ldots, t_{m}\right\}=\left\{t_{j_{1}}, \ldots, s_{j_{m^{\prime}}}\right\} \cup \Pi
\end{aligned}
$$

where $\Pi=\left\{s_{1}, \ldots, s_{n}\right\} \cap\left\{t_{1}, \ldots, t_{m}\right\}, n^{\prime} \neq 0$ and there exists a (possibly partial) surjective function $\varphi:\left\{s_{i_{1}}, \ldots, s_{i_{n^{\prime}}}\right\} \rightarrow\left\{t_{j_{1}}, \ldots, s_{j_{m^{\prime}}}\right\}$ such that $\varphi(s)=t$ implies $s \triangleright t$.

We prove Cands $s_{1} \succ_{c}^{m u l}$ Cands $s_{2}$ by induction on $m^{\prime}$. First, assume $m^{\prime}=0$, i.e. $\left\{t_{1}, \ldots, t_{m}\right\}=$ $\Pi \subset\left\{s_{1}, \ldots, s_{n}\right\}$ (the strict subset inclusion is a consequence of $n^{\prime} \neq 0$ ). This means that for each

$$
\pi^{\prime}=\left\langle c_{1} \cup \ldots \cup c_{m}, p_{1} \cup \ldots \cup p_{m}\right\rangle \in \text { Cands }_{2}
$$

there is a

$$
\pi=\left\langle c_{1} \cup \ldots \cup c_{m} \cup c_{m+1} \cup \ldots \cup c_{n}, p_{1} \cup \ldots \cup p_{m} \cup p_{m+1} \cup \ldots \cup p_{n}\right\rangle
$$

from Cands $s_{1}$, such that $\pi \succ_{c} \pi^{\prime}$ because $c_{1} \cup \ldots \cup c_{m} \cup c_{m+1} \cup \ldots \cup c_{n} \supset c_{1} \cup \ldots \cup c_{m}$ and thus $c_{1} \cup \ldots \cup c_{m} \cup c_{m+1} \cup \ldots \cup c_{n} \succ_{a c}^{m u l} c_{1} \cup \ldots \cup c_{m}$. Hence, we obtain Cands $s_{1} \succ_{c}^{m u l} C a n d s_{2}$.

Now assume $m^{\prime}>0$. There exists a term $s^{\prime} \in\left\{s_{i_{1}}, \ldots, s_{i_{n^{\prime}}}\right\}$, such that $\varphi\left(s^{\prime}\right)=t^{\prime}$ for some $t^{\prime} \in\left\{t_{j_{1}}, \ldots, t_{j_{m^{\prime}}}\right\}$ and such that, additionally, $s^{\prime \prime} \ngtr s^{\prime}$ for all $s^{\prime \prime} \in\left\{s_{i_{1}}, \ldots, s_{i_{n^{\prime}}}\right\}$ for which $\varphi\left(s^{\prime \prime}\right)$ is defined (i.e. we choose a maximal element $s^{\prime}($ w.r.t $\triangleright)$ from $\left.\varphi^{-1}\left(\left\{t_{j_{1}}, \ldots, t_{j_{m^{\prime}}}\right\}\right)\right)$. By Lemma 6, the induction hypothesis is applicable, yielding

$$
\begin{equation*}
\text { Cands } s_{1}^{\prime} \succ_{c}^{m u l} \text { Cands } s_{2}^{\prime} \tag{1}
\end{equation*}
$$

or

$$
\begin{equation*}
C a n d s_{1}^{\prime}=C a n d s_{2}^{\prime} \tag{2}
\end{equation*}
$$

where $C a n d s_{1}^{\prime}$ is

$$
\begin{gathered}
\left\{\left\langle c_{k_{1}} \cup \ldots \cup c_{k_{n-1}}, p_{k_{1}} \cup \ldots \cup p_{k_{n-1}}\right\rangle \mid\right. \\
\quad\left\langle c_{k_{1}}, p_{k_{1}}\right\rangle \in \operatorname{cands}\left(s_{k_{1}}, f\right), \ldots, \\
\left.\left\langle c_{k_{n-1}}, p_{k_{n-1}}\right\rangle \in \operatorname{cands}\left(s_{k_{n-1}}, f\right)\right\},
\end{gathered}
$$

Cands ${ }_{2}^{\prime}$ is

$$
\begin{gathered}
\left\{\left\langle c_{k_{1}^{\prime}}^{\prime} \cup \ldots \cup c_{k_{m-1}^{\prime}}^{\prime}, p_{k_{1}^{\prime}}^{\prime} \cup \ldots \cup p_{k_{m-1}^{\prime}}^{\prime}\right\rangle \mid\right. \\
\left\langle c_{k_{1}^{\prime}}^{\prime}, p_{k_{1}^{\prime}}^{\prime}\right\rangle \in \operatorname{cands}\left(t_{k_{1}^{\prime}}, f\right), \ldots, \\
\\
\left.\left\langle c_{k_{m-1}^{\prime}}^{\prime}, p_{k_{m-1}^{\prime}}^{\prime}\right\rangle \in \operatorname{cands}\left(t_{k_{m-1}^{\prime}}^{\prime}, f\right)\right\}
\end{gathered}
$$

and

$$
\left\{s_{k_{1}}, \ldots, s_{k_{n-1}}\right\}=\left\{s_{1}, \ldots, s_{n}\right\} \backslash\left\{s^{\prime}\right\}
$$

resp.

$$
\left\{t_{k_{1}^{\prime}}, \ldots, t_{k_{m-1}^{\prime}}\right\}=\left\{t_{1}, \ldots, t_{m}\right\} \backslash\left\{t^{\prime}\right\}
$$

With this notation we can write $C a n d s_{1}$ and $C a n d s_{2}$ in the following way.

$$
\begin{aligned}
\text { Cands }_{1}=\left\{\left\langle a_{1} \cup a_{2}, b_{1} \cup b_{2}\right\rangle \mid\right. & \mid\left\langle a_{1}, b_{1}\right\rangle \in \operatorname{Cands} s_{1}^{\prime}, \\
& \left.\left\langle a_{2}, b_{2}\right\rangle \in \operatorname{cands}\left(s^{\prime}, f\right)\right\}
\end{aligned}
$$

and

$$
\left.\left.\begin{array}{rl}
\text { Cands }_{2}=\left\{\left\langle a_{1}^{\prime} \cup a_{2}^{\prime}, b_{1}^{\prime} \cup b_{2}^{\prime}\right\rangle \mid\right. & \mid\left\langle a_{1}^{\prime}, b_{1}^{\prime}\right\rangle
\end{array} \in \text { Cands }_{2}^{\prime}, ~ 子 a_{2}^{\prime}, b_{2}^{\prime}\right\rangle \in \operatorname{cands}\left(t^{\prime}, f\right)\right\} . ~ \$
$$

We are going to show that for every pair $\alpha^{\prime}$ from $C a n d s_{2}$ there exists a pair $\alpha$ from $C a n d s_{1}$ with $\alpha \succ_{c} \alpha^{\prime}$ which concludes the proof as it implies Cands $\succ_{c} \succ_{c}^{m u l} C a n d s_{2}$. So consider some arbitrary pair $\left\langle a_{1}^{\prime} \cup a_{2}^{\prime}, b_{1}^{\prime} \cup b_{2}^{\prime}\right\rangle$ where $\left\langle a_{1}^{\prime}, b_{1}^{\prime}\right\rangle \in C a n d s_{2}^{\prime}$ and
$\left\langle a_{2}^{\prime}, b_{2}^{\prime}\right\rangle \in \operatorname{cands}\left(t^{\prime}, f\right)$. Now we distinguish several cases, depending on the kind of pairs contained in Cands $s_{1}^{\prime}$ and $\operatorname{cands}\left(s^{\prime}, f\right)$.

First, assume there exists a pair $\left\langle a_{2}, b_{2}\right\rangle \in \operatorname{cands}\left(s^{\prime}, f\right)$ with $a_{2} \succ_{a c}^{m u l} a_{2}^{\prime}$. By our induction hypothesis, there must be a pair $\left\langle a_{1}, b_{1}\right\rangle \in \operatorname{Cands} s_{1}^{\prime}$ with $a_{1}=a_{1}^{\prime}$ or $a_{1} \succ_{a c}^{m u l} a_{1}^{\prime}$ (because otherwise Cands $s_{1}^{\prime} \nsucceq_{c}^{m u l} C a n d s_{2}^{\prime}$ ) and thus $a_{1} \cup a_{2} \succ_{c}^{m u l} a_{1}^{\prime} \cup a_{2}^{\prime}$, yielding $\left\langle a_{1} \cup a_{2}, b_{1} \cup b_{2}\right\rangle \succ_{c}\left\langle a_{1}^{\prime} \cup a_{2}^{\prime}, b_{1}^{\prime} \cup\right.$ $\left.b_{2}^{\prime}\right\rangle$. Second, assume there exists a pair $\left\langle a_{1}, b_{1}\right\rangle \in$ Cands ${ }_{1}^{\prime}$ with $a_{1} \succ_{a c}^{m u l} a_{1}^{\prime}$. Then, by Lemma 5, there must be a pair $\left\langle a_{2}, b_{2}\right\rangle \in \operatorname{cands}\left(s^{\prime}, f\right)$ such that $a_{2}=a_{2}^{\prime}$ or $a_{2} \succ_{a c}^{m u l} a_{2}^{\prime}$. Thus, we have $a_{1} \cup a_{2} \succ_{a c}^{m u l} a_{1}^{\prime} \cup a_{2}^{\prime}$, yielding $\left\langle a_{1} \cup a_{2}, b_{1} \cup b_{2}\right\rangle \succ_{c}\left\langle a_{1}^{\prime} \cup a_{2}^{\prime}, b_{1}^{\prime} \cup b_{2}^{\prime}\right\rangle$. Third, assume there is no pair $\left\langle a_{2}, b_{2}\right\rangle \in \operatorname{cands}\left(s^{\prime}, f\right)$ with $a_{2} \succ_{a c}^{m u l} a_{2}^{\prime}$ and no pair $\left\langle a_{1}, b_{1}\right\rangle \in C a n d s_{1}^{\prime}$ with $a_{1} \succ_{a c}^{m u l} a_{1}^{\prime}$. The rest of the proof is dedicated to deal with this final case.

By the induction hypothesis there exists a pair $\left\langle a_{1}, b_{1}\right\rangle \in$ Cands $_{1}^{\prime}$ such that either $\left\langle a_{1}, b_{1}\right\rangle=$ $\left\langle a_{1}^{\prime}, b_{1}^{\prime}\right\rangle$ or $\left\langle a_{1}, b_{1}\right\rangle \succ_{c}\left\langle a_{1}^{\prime}, b_{1}^{\prime}\right\rangle$. We deal with these two possibilities separately. Assume $\left\langle a_{1}, b_{1}\right\rangle=$ $\left\langle a_{1}^{\prime}, b_{1}^{\prime}\right\rangle$ first. We know that there exists a pair $\left\langle a_{2}, b_{2}\right\rangle \in \operatorname{cands}\left(s^{\prime}, f\right)$ with $\left\langle a_{2}, b_{2}\right\rangle \succ_{c}\left\langle a_{2}^{\prime}, b_{2}^{\prime}\right\rangle$ by Lemma 5. Moreover, as $a_{2} \succ_{a c}^{m u l} a_{2}^{\prime}$, we have $a_{2}=a_{2}^{\prime}$ according to [20][Definition 17]. Hence, according to $[20]\left[\right.$ Definition 17] $\left\langle a_{2}, b_{2}\right\rangle \succ_{c}\left\langle a_{2}^{\prime}, b_{2}^{\prime}\right\rangle$ means that $b_{2} \backslash b_{2}^{\prime} \neq \emptyset$ and for each pair $\alpha^{\prime} \in b_{2}^{\prime} \backslash b_{2}$, there is a pair $\alpha \in b_{2} \backslash b_{2}^{\prime}$, with $\alpha \succ_{p} \alpha^{\prime}$. The ordering $\succ_{p}$ is the ordering $\succ$ of [20][Definition 17].

We have $a_{1} \cup a_{2}=a_{1}^{\prime} \cup a_{2}^{\prime}$ and $b_{1} \cup b_{2} \backslash b_{1}^{\prime} \cup b_{2}^{\prime} \neq \emptyset$, because $b_{1}=b_{1}^{\prime}$. Moreover, for every pair $\alpha^{\prime} \in b_{1}^{\prime} \cup b_{2}^{\prime} \backslash b_{1} \cup b_{2}$ there is a pair $\alpha \in b_{1} \cup b_{2} \backslash b_{1}^{\prime} \cup b_{2}^{\prime}$ such that $\alpha \succ_{p} \alpha^{\prime}$, because $b_{1}^{\prime} \cup b_{2}^{\prime} \backslash b_{1} \cup b_{2}=b_{2}^{\prime} \backslash b_{2}$ and $b_{1} \cup b_{2} \backslash b_{1}^{\prime} \cup b_{2}^{\prime}=b_{2} \backslash b_{2}^{\prime}$, as $b_{1}=b_{1}^{\prime}$. Thus, we have $\left\langle a_{1} \cup a_{2}, b_{1} \cup b_{2}\right\rangle \succ_{c}\left\langle a_{1}^{\prime} \cup a_{2}^{\prime}, b_{1}^{\prime} \cup b_{2}^{\prime}\right\rangle$.

Second, assume $\left\langle a_{1}, b_{1}\right\rangle \succ_{c}\left\langle a_{1}^{\prime}, b_{1}^{\prime}\right\rangle$. Since $a_{1} \succ_{a c}^{m u l} a_{1}^{\prime}$ we have $a_{1}=a_{1}^{\prime}$. Hence, $\left\langle a_{1}, b_{1}\right\rangle \succ_{c}\left\langle a_{1}^{\prime}, b_{1}^{\prime}\right\rangle$ means that $b_{1} \backslash b_{1}^{\prime} \neq \emptyset$ and for every pair $\alpha^{\prime} \in b_{1}^{\prime} \backslash b_{1}$, there exists a pair $\alpha \in b_{1} \backslash b_{1}^{\prime}$ such that $\alpha \succ_{p} \alpha^{\prime}$. Moreover, there exists a pair $\left\langle a_{2}, b_{2}\right\rangle$ with $a_{2}=a_{2}^{\prime}$ and $\left\langle a_{2}, b_{2}\right\rangle \succ_{c}\left\langle a_{2}^{\prime}, b_{2}^{\prime}\right\rangle$ according to Lemma 5.

We have $a_{1} \cup a_{2}=a_{1}^{\prime} \cup a_{2}^{\prime}$. In order to prove $\left\langle a_{1} \cup a_{2}, b_{1} \cup b_{2}\right\rangle \succ_{c}\left\langle a_{1}^{\prime} \cup a_{2}^{\prime}, b_{1}^{\prime} \cup b_{2}^{\prime}\right\rangle$ we need to show $b_{1} \cup b_{2} \backslash b_{1}^{\prime} \cup b_{2}^{\prime} \neq \emptyset$ and that for every pair $\alpha^{\prime} \in b_{1}^{\prime} \cup b_{2}^{\prime} \backslash b_{1} \cup b_{2}$ there is a pair $\alpha \in b_{1} \cup b_{2} \backslash b_{1}^{\prime} \cup b_{2}^{\prime}$, with $\alpha \succ_{p} \alpha^{\prime}$. We distinguish two cases to prove that

$$
\begin{equation*}
b_{1} \cup b_{2} \backslash b_{1}^{\prime} \cup b_{2}^{\prime} \supseteq b_{2} \backslash b_{2}^{\prime} \neq \emptyset: \tag{3}
\end{equation*}
$$

If $s^{\prime}$ is a ground term, then it is a small term and thus $\operatorname{cands}\left(s^{\prime}, f\right)=\left\{\left\langle\{a\},\left\{\left\langle\{a\}, s^{\prime}\right\rangle\right\}\right\rangle\right\}$ (i.e. $\left.b_{2}=\left\{\left\langle\{a\}, s^{\prime}\right\rangle\right\}\right)$. In that case $t^{\prime}$ is a small term as well and $\operatorname{cands}\left(t^{\prime}, f\right)=\left\{\left\langle\{a\},\left\{\left\langle\{a\}, t^{\prime}\right\rangle\right\}\right\rangle\right\}$. Now because of the particular choice of $s^{\prime}$, the number of occurrences of $s^{\prime}$ in $\left\{t_{k_{1}^{\prime}}, \ldots, t_{k_{m-1}^{\prime}}\right\}$ must be less or equal than the occurrences of $s^{\prime}$ in $\left\{s_{k_{1}}, \ldots, s_{k_{n-1}}\right\}$. Hence, the number of pairs $\left\langle\{a\}, s^{\prime}\right\rangle$ in $b_{1}^{\prime}$ must be less or equal than the number of these pairs in $b_{1}$. Now since the number of $\left\langle\{a\}, s^{\prime}\right\rangle$ pairs in $b_{1} \cup b_{2}$ equals the number of these pairs in $b_{1}+1$, while the number of these pairs in $b_{1}^{\prime} \cup b_{2}^{\prime}$ equals that in $b_{1}^{\prime}$, we have strictly more occurrences of $\left\langle\{a\}, s^{\prime}\right\rangle$ in $b_{1} \cup b_{2}$ than in $b_{1}^{\prime} \cup b_{2}^{\prime}$ and thus $b_{1} \cup b_{2} \backslash b_{1}^{\prime} \cup b_{2}^{\prime} \supseteq\left\{\left\langle\{a\}, s^{\prime}\right\rangle\right\}=b_{2} \backslash b_{2}^{\prime}$.

Otherwise, $s^{\prime}$ is not a ground term. Then pairs in $b_{2}$ are of the shape $\left\langle\{x\}, s^{\prime}\right\rangle$ for some variable $x$ of $s^{\prime}$. No term from $\left\{t_{k_{1}^{\prime}}, \ldots, t_{k_{m-1}^{\prime}}\right\}$ can contain any variable occurring in $s^{\prime}$, since otherwise, because of $\left\{s_{k_{1}}, \ldots, s_{k_{n-1}}\right\} \triangleright^{t u p}\left\{t_{k_{1}^{\prime}}, \ldots, t_{k_{m-1}^{\prime}}\right\}$, some term of $\left\{s_{k_{1}}, \ldots, s_{k_{n-1}}\right\}$ would have to contain the same variables and that would be a contradiction to variable disjointness of terms of $\left\{s_{1}, \ldots, s_{n}\right\}=\left\{s_{k_{1}}, \ldots, s_{k_{n-1}}\right\} \cup\left\{s^{\prime}\right\}$. Hence, we have $b_{2} \backslash b_{1}^{\prime}=b_{2}$ and thus $b_{1} \cup b_{2} \backslash b_{1}^{\prime} \cup b_{2}^{\prime} \supseteq b_{2} \backslash b_{2}^{\prime}$.

Now, we show that for every pair $\alpha^{\prime} \in b_{1}^{\prime} \cup b_{2}^{\prime} \backslash b_{1} \cup b_{2}$ there is a pair $\alpha \in b_{1} \cup b_{2} \backslash b_{1}^{\prime} \cup b_{2}^{\prime}$, with $\alpha \succ_{p} \alpha^{\prime}$. We distinguish several cases: First, assume $\alpha^{\prime} \in b_{2}^{\prime} \backslash b_{1} \cup b_{2}$. Thus, there is a pair $\alpha \in b_{2} \backslash b_{2}^{\prime}$, such that $\alpha \succ_{p} \alpha^{\prime}$. However, since $b_{2} \backslash b_{2}^{\prime} \subseteq b_{1} \cup b_{2} \backslash b_{1}^{\prime} \cup b_{2}^{\prime}$, we have $\alpha \in b_{1} \cup b_{2} \backslash b_{1}^{\prime} \cup b_{2}^{\prime}$.

Second, assume $\alpha^{\prime} \in b_{1}^{\prime} \backslash b_{1} \cup b_{2}$. We further distinguish two cases, depending on whether $\alpha^{\prime}$ has the shape $\langle\{a\}, t\rangle$ (i.e. it goes back to a small term $t$ ) or $\langle\{x\}, t\rangle$ (i.e. it goes back to a non-ground term $t$ ). Assume $\alpha^{\prime}=\langle\{a\}, t\rangle$ for some term $t$. We know that there is a pair $\alpha \in b_{1} \backslash b_{1}^{\prime}$ with $\alpha \succ_{p} \alpha^{\prime}$. If $\alpha \in b_{1} \backslash b_{1}^{\prime} \cup b_{2}^{\prime}$ we are done. Otherwise, $b_{2}^{\prime}=\{\alpha\}$ and $t=t^{\prime}$ (cf. [20][Definition 12]). Moreover, we have $b_{2} \backslash b_{2}^{\prime} \supseteq\left\{\alpha^{\prime \prime}\right\}$ with $\alpha^{\prime \prime} \succ_{p} \alpha$ and since $b_{1} \cup b_{2} \backslash b_{1}^{\prime} \cup b_{2}^{\prime} \supseteq b_{2} \backslash b_{2}^{\prime}$ (3) we have $\alpha^{\prime \prime} \in b_{1} \cup b_{2} \backslash b_{1}^{\prime} \cup b_{2}^{\prime}$. By transitivity of $\succ_{p}$ we get $\alpha^{\prime \prime} \succ_{p} \alpha^{\prime}\left(\alpha^{\prime \prime} \succ_{p} \alpha \succ_{p} \alpha^{\prime}\right)$.

Now, assume $\alpha^{\prime}=\langle\{x\}, t\rangle$ for some term $t$ and variable $x \in t$. Then, there is a pair $\alpha \in b_{1} \backslash b_{1}^{\prime}$ with $\alpha \succ_{p} \alpha^{\prime} .\left\langle a_{1}, b_{1}\right\rangle \in \operatorname{Cands} s_{1}^{\prime}$. Hence, $x \in \operatorname{Var}\left(s_{k_{1}}\right) \cup \ldots \cup \operatorname{Var}\left(s_{k_{n-1}}\right)$ and thus $x \notin s^{\prime}$, because the terms in $\left\{s_{1}, \ldots, s_{n}\right\}=\left\{s_{k_{1}}, \ldots, s_{k_{n-1}}\right\} \cup\left\{s^{\prime}\right\}$ are pairwise variable disjoint. This means $x \notin t^{\prime}$, as $s^{\prime} \triangleright t^{\prime}$ and thus there is no pair $\left\langle p_{1}, p_{2}\right\rangle \in \operatorname{cands}\left(t^{\prime}, f\right)$ where $\alpha \in p_{2}$. Hence, $\alpha \in b_{1} \backslash b_{1}^{\prime} \cup b_{2}^{\prime}$ and $\alpha \succ_{p} \alpha^{\prime}$.

The final lemma justifies the use of flattened terms when comparing arguments of $A C$ function symbols in Definition 8.

Lemma 8. Let $\Sigma$ be an unsorted signature and $\succ_{a c}$ be an ACRPO on $\mathcal{T}(\Sigma, V)$ where $<$ is the used precedence. Given a term $t$, such that all proper subterms of flat $(t, f)$ are from $\mathcal{T}\left(\Sigma^{<f}, V\right)$, then we have cands $(t, f)=\operatorname{cands}(f l a t(t, f), f)$.

Proof. Let $t^{\prime}=f l a t(t, f)$. We prove the result by induction on the arity of $\operatorname{root}\left(t^{\prime}\right)$ (denoted $\left.\operatorname{ar}\left(\operatorname{root}\left(t^{\prime}\right)\right)\right)$. If this arity is 2 , then $t=t^{\prime}$ according to Definitions 2 and 8 . Otherwise, assume we have $\operatorname{ar}\left(\operatorname{root}\left(t^{\prime}\right)\right)=k>2$. If $\operatorname{root}(t) \neq f$, we have $t=t^{\prime}$ and the result holds trivially. So assume $t=f\left(t_{1}, t_{2}\right)$. Then, if $t^{\prime}=f\left(t_{1}^{\prime}, \ldots, t_{k}^{\prime}\right)$ we have $\operatorname{flat}\left(t_{1}, f\right)=f\left(t_{i_{1}^{\prime}}^{\prime}, \ldots, t_{i_{l_{1}}}^{\prime}\right)$ and $f l a t\left(t_{2}, f\right)=$ $f\left(t_{j_{1}^{\prime}}^{\prime}, \ldots, t_{j_{l_{2}}}^{\prime}\right)$ such that $\left\{t_{i_{1}}^{\prime}, \ldots, t_{i_{l_{1}}}^{\prime}, t_{j_{1}}^{\prime}, \ldots t_{j_{l_{2}}}^{\prime}\right\}=\left\{t_{1}, \ldots, t_{k}\right\}$ (here if $l_{1}$ or $l_{2}$ is one, then $f\left(t_{i_{1}}^{\prime}\right)$ (resp. $f\left(t_{j_{1}}^{\prime}\right)$ ) denotes $t_{i_{1}}^{\prime}$ (resp. $\left.t_{j_{1}}^{\prime}\right)$ ).

By Definition 2 the arity of $\operatorname{root}\left(f l a t\left(t_{i}, f\right)\right)$ is less than $k$ for both $i \in\{1,2\}$. Hence, the induction hypothesis applies yielding $\operatorname{cands}\left(t_{1}, f\right)=\operatorname{cands}\left(f l a t\left(t_{1}, f\right), f\right)$ which is given by

$$
\begin{aligned}
& \left\{c_{i_{1}}^{\prime} \cup \ldots \cup c_{i_{1}}^{\prime}, p_{i_{1}}^{\prime} \cup \ldots \cup p_{i_{l_{1}}}^{\prime \prime} \mid\right. \\
& \left.\left\langle c_{i_{1}}^{\prime}, p_{i_{1}}^{\prime}\right\rangle \in \operatorname{cands}\left(t_{i_{1}}^{\prime}, f\right), \ldots,\left\langle c_{i_{l_{1}}}^{\prime}, p_{i_{l_{1}}}^{\prime}\right\rangle \in \operatorname{cands}\left(t_{i_{l_{1}}}^{\prime}, f\right)\right\}
\end{aligned}
$$

and $\operatorname{cands}\left(t_{2}, f\right)=\operatorname{cands}\left(f l a t\left(t_{2}, f\right), f\right)$ which is given by

$$
\begin{aligned}
& c_{j_{1}}^{\prime} \cup \ldots \cup c_{j_{l_{2}}}^{\prime}, p_{j_{1}}^{\prime} \cup \ldots \cup p_{j_{l_{2}}}^{\prime \prime} \mid \\
& \left.\quad\left\langle c_{j_{1}}^{\prime}, p_{j_{1}}^{\prime}\right\rangle \in \operatorname{cands}\left(t_{j_{1}}^{\prime}, f\right), \ldots,\left\langle c_{j_{l_{2}}}^{\prime}, p_{j_{l_{2}}}^{\prime}\right\rangle \in \operatorname{cands}\left(t_{j_{l_{2}}}^{\prime}, f\right)\right\}
\end{aligned}
$$

By [20][Definition 12], we have

$$
\left.\left.\begin{array}{rl}
\operatorname{cands}(t, f)=\left\{\left\langle c_{1} \cup c_{2}, p_{1} \cup p_{2}\right|\right. & \left\langle c_{1}, p_{1}\right\rangle
\end{array} \in \operatorname{cands}\left(t_{1}, f\right), ~ 子, ~<c_{2}, p_{2}\right\rangle \in \operatorname{cands}\left(t_{2}, f\right)\right\}, ~ \$
$$

which is thus the same as

$$
\begin{aligned}
& \left\{\left\langle\left(c_{i_{1}}^{\prime} \cup \ldots \cup c_{i_{l_{1}}}^{\prime}\right) \cup\left(c_{j_{1}}^{\prime} \cup \ldots \cup c_{j_{l_{2}}}^{\prime}\right)\right.\right. \\
& \left.\left(p_{i_{1}}^{\prime} \cup \ldots \cup p_{i_{l_{1}}}^{\prime}\right) \cup\left(p_{j_{1}}^{\prime} \cup \ldots \cup p_{j_{l_{2}}}^{\prime}\right)\right\rangle \mid \\
& \left\langle c_{i_{1}}^{\prime}, p_{i_{1}}^{\prime}\right\rangle \in \operatorname{cands}\left(t_{i_{1}}^{\prime}, f\right), \ldots,\left\langle c_{i_{l_{1}}}^{\prime}, p_{i_{l_{1}}}^{\prime}\right\rangle \in \operatorname{cands}\left(t_{i_{l_{1}}}^{\prime}, f\right) \\
& \left.\left\langle c_{j_{1}}^{\prime}, p_{j_{1}}^{\prime}\right\rangle \in \operatorname{cands}\left(t_{j_{1}}^{\prime}, f\right), \ldots,\left\langle c_{j_{l_{2}}}^{\prime}, p_{j_{l_{2}}}^{\prime}\right\rangle \in \operatorname{cands}\left(t_{j_{l_{2}}}^{\prime}, f\right)\right\} .
\end{aligned}
$$

By associativity and commutativity of $\cup$ (for multisets) this further equals

$$
\begin{aligned}
\left\{\left\langle c_{1}^{\prime} \cup \ldots \cup c_{k}^{\prime}, p_{1}^{\prime} \cup \ldots \cup p_{k}^{\prime}\right|\right. & \left\langle c_{1}, p_{1}\right\rangle
\end{aligned} \in \operatorname{cands}\left(t_{1}^{\prime}, f\right), \ldots,
$$

which is $\operatorname{cands}\left(t^{\prime}, f\right)$ by [20][Definition 12].
The next lemma states stability of under $A C$-instantiations.
Lemma 9. Let $\Sigma$ be an unsorted signature and let $s, t \in \mathcal{T}(\Sigma, V)$ such that $\operatorname{root}(s)=\operatorname{root}(t)=$ $f \in \Sigma_{A C}$ and $\theta$ be a specialization such that $\operatorname{lab}(\operatorname{root}(\overline{s \theta})) \geq{ }^{\text {mul }} \operatorname{lab}(\operatorname{root}(\overline{t \theta}))$. Consider the multiset $S$ of arguments of $\operatorname{root}(\overline{s \theta})$ in the term $\overline{s \theta}$ as well as the multiset $T$ of arguments of $\operatorname{root}(\overline{t \theta})$ in the term $\overline{t \theta}$. Assume that for every variable $x \in T \backslash S$, there exists a term $s^{\prime} \in S \backslash T$, such that $l s\left(s^{\prime}\right)>l s(x)$. Moreover, let $\operatorname{root}(\overline{s \theta})=f_{\Psi}$ and $\operatorname{root}(\overline{t \theta})=f_{\Psi^{\prime}}$. Then for every substitution $\sigma$ with $l s(x \sigma)=l s(x \theta)$ for all $x \in \operatorname{Dom}(\sigma)$ we have that $\operatorname{root}(\overline{s \sigma})=f_{\widetilde{\Psi}}$ and $\operatorname{root}(\overline{t \sigma})=f_{\widetilde{\Psi}^{\prime}}$ implies $\widetilde{\Psi} \geq^{m u l} \widetilde{\Psi}^{\prime}$.

Proof. If there is no variable in $T \backslash S$, then $\widetilde{\Psi}^{\prime} \backslash \widetilde{\Psi}=\operatorname{lab}(\operatorname{root}(\overline{t \theta})) \backslash \operatorname{lab}(\operatorname{root}(\overline{\operatorname{s\theta }}))$ and thus $\widetilde{\Psi} \geq^{m u l} \widetilde{\Psi}^{\prime}$.
Otherwise, for each sort $u \in \widetilde{\Psi}^{\prime} \backslash \widetilde{\Psi}$ there is a sort $u^{\prime}>u \in \widetilde{\Psi} \backslash \widetilde{\Psi}^{\prime}$ and $\widetilde{\Psi} \backslash \widetilde{\Psi}^{\prime}$ is non-empty, hence $\widetilde{\Psi}>^{m u l} \widetilde{\Psi}^{\prime}$.

Finally, we can prove finiteness of $A C$-rewrite derivations w.r.t. well-founded OS theories.
Theorem 1. Let $\mathcal{E}=\left(\Sigma, B_{0}, R\right)$ be a sort-decreasing well-founded recursive OS theory where the structural axioms $B_{0}$ are either $A C$ or $C$ axioms. Then $\mathcal{E}$ is $B_{0}$-terminating.
Proof. We prove that $\widetilde{\mathcal{E}}=\left(\Sigma^{o s}, \widetilde{B_{0}}, \widetilde{R}\right)$ is compatible with an $A C R P O$ as defined in [20] (which implies termination of $\mathcal{E}$ by Lemma 4). Note that there is no lexicographic comparison of arguments of non-commutative function symbol in the definition of the $A C R P O$ in [20]. However, an inspection of the proofs reveals that the results remain valid also in the presence of lexicographic comparisons of arguments of non-commutative functions. This is also claimed in [20].

Assume $\mathcal{E}$ is well-founded recursive w.r.t. to the status functions stat and stat ${ }_{a c}$. The non-strict precedence $\gtrsim$ on function symbols of $\Sigma^{o s}$ that we use is the smallest precedence satisfying $f>g$ if:
$-f \nabla_{\overline{\mathcal{E}}} g, g{ }_{\overline{\mathcal{E}}} f$ and either $f$ or $g$ is not an $A C$ symbol; and
$-f$ and $g$ are both $A C$ symbols, $f{ }_{\overline{\mathcal{E}}} g, g \downarrow_{\overline{\mathcal{E}}} f$ and either $\operatorname{erase}(g) \bigvee_{\mathcal{E}} \operatorname{erase}(f)$ or $\operatorname{stat}_{a c}(f)=$ $s t a t_{a c}(g)=s$; and
$-f$ is an $A C$ symbol and there exists a rule $l \rightarrow r \in \widetilde{R}$ such that $\operatorname{root}(l)=f$ and $\operatorname{root}\left(\left.l\right|_{p}\right)=g$ for some position $p \in \operatorname{Pos}_{\Sigma}(l)$.

Moreover, two function symbols $f$ and $g$ are equal if
$-f>_{\overline{\mathcal{E}}} g, g{ }_{\overline{\mathcal{E}}} f$; and
$-f$ and $g$ are both $A C$ symbols, $\operatorname{erase}(f) \wedge_{\mathcal{E}} \operatorname{erase}(g), \operatorname{erase}(g) \vee_{\mathcal{E}} \operatorname{erase}(f)$ and $\operatorname{stat}_{a c}(f)=$ $s t a t_{a c}(g)=u s$.

The strict part of the precedence is well-founded because $\Sigma$ is finite and whenever $f>g$ for $A C$ symbols $f$ and $g$, then $\operatorname{lab}(f)>^{m u l} l a b(g)$ where $<$ is the subsort ordering of $\Sigma$.

Now, consider a rule $l \rightarrow r \in \widetilde{R}$ that is obtained through instantiation and labeling from an equation $l^{\prime} \rightarrow r^{\prime} \in R$. We prove that $l \succ_{a c} w$ for every (not necessarily proper) subterm $w$ of $r$ by induction on the depth of $w$. For the base case, let $w$ be a variable. Since $l$ is not a variable, we have $l \triangleright w$ and since $\succ_{a c}$ is a simplification ordering we get $l \succ_{a c} w$.

In the step case, by Definitions 8 and $13, \operatorname{root}(w)=\operatorname{root}\left(\overline{\left.r^{\prime}\right|_{p} \theta}\right)$ for some specialization $\theta$ and position $p \in \operatorname{Pos}\left(r^{\prime}\right)$ and thus $\operatorname{root}(l) \gtrsim \operatorname{root}(w)$ by Lemma 9 . In case $\operatorname{root}(l)>\operatorname{root}(w)$ we have $\left.l \succ_{a c} w\right|_{1}, \ldots,\left.l \succ_{a c} w\right|_{a r(w)}$ by the induction hypothesis, and thus $l \succ_{a c} w$.

Otherwise $\operatorname{root}(l) \sim \operatorname{root}(w)$ and thus $\operatorname{root}(l)$ and $\operatorname{root}(w)$ are both $A C$ symbols or both not $A C$ symbols. By Definition 8 there are terms $l^{\prime}={ }_{B_{0}} l$ and $w^{\prime}={ }_{B_{0}} w$ such that

$$
\left\{\left.l^{\prime \prime}\right|_{1}, \ldots,\left.l^{\prime \prime}\right|_{\operatorname{ar}\left(\operatorname{root}\left(l^{\prime \prime}\right)\right)}\right\} \triangleright^{t u p}\left\{\left.w^{\prime \prime}\right|_{1}, \ldots,\left.w^{\prime \prime}\right|_{\operatorname{ar}\left(\operatorname{root}\left(w^{\prime \prime}\right)\right)}\right\}
$$

$\left(\right.$ where $l^{\prime \prime}=\operatorname{flat}\left(l^{\prime}, \operatorname{root}\left(l^{\prime}\right)\right.$ and $\left.w^{\prime \prime}=\operatorname{flat}\left(w^{\prime}, \operatorname{root}\left(w^{\prime}\right)\right)\right)$ or

$$
\left\{\left.l^{\prime}\right|_{1}, \ldots,\left.l^{\prime}\right|_{\operatorname{ar}\left(\operatorname{root}\left(l^{\prime}\right)\right)}\right\} \triangleright^{m u l}\left\{\left.w^{\prime}\right|_{1}, \ldots,\left.w^{\prime}\right|_{\operatorname{ar(root}(w))}\right\}
$$

respectively, depending on whether $\operatorname{root}\left(l^{\prime}\right)$ and $\operatorname{root}\left(w^{\prime}\right)$ are both $A C$-symbols or not, in case $\operatorname{stat}(\operatorname{root}(l))=\operatorname{stat}(\operatorname{root}(w))=m u l$ or

$$
\left\{\left.l^{\prime}\right|_{1}, \ldots,\left.l^{\prime}\right|_{\operatorname{ar}\left(\operatorname{root}\left(l^{\prime}\right)\right)}\right\} \triangleright^{l e x}\left\{\left.w^{\prime}\right|_{1}, \ldots,\left.w^{\prime}\right|_{\operatorname{ar}(\operatorname{root}(w))}\right\}
$$

in case $\operatorname{stat}(\operatorname{root}(l))=\operatorname{stat}(\operatorname{root}(w))=l e x$. By $A C$-compatibility of $\succ_{a c}$ it suffices to prove $l^{\prime} \succ_{a c} w^{\prime}$. We distinguish two cases, depending on whether $\operatorname{root}\left(l^{\prime}\right)$ and $\operatorname{root}\left(w^{\prime}\right)$ are $A C$ or non$A C$-symbols.

First, if they are not $A C$-symbols, we have

$$
\left\{\left.l^{\prime}\right|_{1}, \ldots,\left.l^{\prime}\right|_{\operatorname{ar}\left(\operatorname{root}\left(l^{\prime}\right)\right)}\right\} \succ_{a c}^{m u l}\left\{\left.w^{\prime}\right|_{1}, \ldots,\left.w^{\prime}\right|_{\operatorname{ar}(\operatorname{root}(w))}\right\}
$$

in case $\operatorname{stat}(\operatorname{root}(l))=\operatorname{stat}(\operatorname{root}(w))=m u l$ and

$$
\left\{\left.l^{\prime}\right|_{1}, \ldots,\left.l^{\prime}\right|_{\operatorname{ar}\left(\operatorname{root}\left(l^{\prime}\right)\right)}\right\} \succ_{a c}^{l e x}\left\{\left.w^{\prime}\right|_{1}, \ldots,\left.w^{\prime}\right|_{\operatorname{ar}(\operatorname{root}(w))}\right\}
$$

in case $\operatorname{stat}(\operatorname{root}(l))=\operatorname{stat}(\operatorname{root}(w))=\operatorname{lex}$ because by Definition 8 we have

$$
\left\{\left.l^{\prime}\right|_{1}, \ldots,\left.l^{\prime}\right|_{\operatorname{ar}\left(\operatorname{root}\left(l^{\prime}\right)\right)}\right\} \triangleright^{m u l}\left\{\left.w^{\prime}\right|_{1}, \ldots,\left.w^{\prime}\right|_{\operatorname{ar}(\operatorname{root}(w))}\right\}
$$

resp.

$$
\left\{\left.l^{\prime}\right|_{1}, \ldots,\left.l^{\prime}\right|_{\operatorname{ar}\left(\operatorname{root}\left(l^{\prime}\right)\right)}\right\} \triangleright^{l e x}\left\{\left.w^{\prime}\right|_{1}, \ldots,\left.w^{\prime}\right|_{\operatorname{ar}(\operatorname{root}(w))}\right\}
$$

and since $\succ_{a c} \supseteq \triangleright\left(\succ_{a c}\right.$ is a simplification ordering) we get $l^{\prime} \succ_{a c} w^{\prime}$ according to [20][Definition 17].

Second, if both $\operatorname{root}\left(w^{\prime}\right)$ and $\operatorname{root}\left(l^{\prime}\right)$ are $A C$ symbols, according to [20][Definition 17], we have to prove $\operatorname{cands}\left(l^{\prime}, \operatorname{root}\left(l^{\prime}\right)\right) \succ_{c}^{m u l} \operatorname{cands}\left(w^{\prime}, \operatorname{root}\left(w^{\prime}\right)\right)(\operatorname{cf.}[20][D e f i n i t i o n s 12$ and 17]). By, Lemma 8 this is the same as proving $\operatorname{cands}\left(l^{\prime \prime}, \operatorname{root}\left(l^{\prime \prime}\right)\right) \succ_{c}^{m u l} \operatorname{cands}\left(w^{\prime \prime}, \operatorname{root}\left(w^{\prime \prime}\right)\right)$ In the sequel let $l^{\prime \prime}=f\left(s_{1}, \ldots, s_{n}\right)$ and $w^{\prime \prime}=g\left(t_{1}, \ldots, t_{m}\right)\left(\right.$ hence $\operatorname{root}\left(l^{\prime \prime}\right)=f$ and $\left.\operatorname{root}\left(w^{\prime \prime}\right)=g\right)$.

The multiset $\operatorname{cands}\left(l^{\prime \prime}, f\right)$ is given by

$$
\begin{aligned}
\left\{\left\langle c_{1} \cup \ldots \cup c_{n}, p_{1} \cup \ldots \cup p_{n}\right\rangle \mid\right. & \mid\left\langle c_{1}, p_{1}\right\rangle \in \operatorname{cands}\left(s_{1}, f\right), \ldots, \\
& \left.\left\langle c_{n}, p_{n}\right\rangle \in \operatorname{cands}\left(s_{n}, f\right)\right\} .
\end{aligned}
$$

Analogously, $\operatorname{cands}\left(w^{\prime}, g\right)$ is given by

$$
\begin{aligned}
\left\{\left\langle c_{1}^{\prime} \cup \ldots \cup c_{m}^{\prime}, p_{1}^{\prime} \cup \ldots \cup p_{m}^{\prime}\right\rangle\right. & \mid\left\langle c_{1}^{\prime}, p_{1}^{\prime}\right\rangle \in \operatorname{cands}\left(t_{1}^{\prime}, f\right), \ldots \\
& \left.\left\langle c_{m}^{\prime}, p_{m}^{\prime}\right\rangle \in \operatorname{cands}\left(t_{m}^{\prime}, f\right)\right\}
\end{aligned}
$$

Note that $f \sim g$ means that $\operatorname{cands}(s, f)=\operatorname{cands}(s, g)$ for all terms $s$.
Since $l^{\prime \prime}$ and $w^{\prime \prime}$ are patterns and thus linear, the terms in the sets $\left\{s_{1}, \ldots, s_{n}\right\}$ and $\left\{t_{1}, \ldots, t_{m}\right\}$ are pairwise variable disjoint. Moreover, by Definition 8 all terms $s_{1}, \ldots, s_{n}, t_{1}, \ldots, t_{m}$ contain only function symbols smaller than $f$ (and $g$ ) in the precedence. Hence, since $\left\{s_{1}, \ldots, s_{n}\right\} \triangleright^{\text {tup }}$ $\left\{t_{1}, \ldots, t_{m}\right\}$, Lemma 7 is applicable, yielding $\operatorname{cands}\left(l^{\prime \prime}, f\right) \succ_{c}^{m u l} \operatorname{cands}\left(w^{\prime \prime}, g\right)$, and thus $l^{\prime} \succ_{a c} w^{\prime}$ according to [20][Definition 17].

Theorem 2. For any well-founded recursive tower as in Definition 9, the equational theory $\left(\Omega \cup\left\{f_{1}, \ldots, f_{m}\right\}, R_{f_{1}} \cup \ldots \cup R_{f_{m}}\right)$ is a well-founded recursive many-sorted theory.
Proof. We prove that $\mathcal{E}=\left(\Omega \cup\left\{f_{1}, \ldots, f_{m}\right\}, R_{f_{1}} \cup \ldots \cup R_{f_{m}}\right)$ is well-founded recursive according to Definition 8 . We use a status function stat that maps every function symbol to lex, i.e. stat $(g)=l e x$ for all $g \in \Omega \cup\left\{f_{1}, \ldots, f_{m}\right\}$. Since we do not have any axioms (and thus in particular no commutative and associative function symbols), stat ${ }_{a c}$ is irrelevant.

Since there are no mutually recursive functions, the constraints for stat in Definition 8 are trivially satisfied.

Moreover, item 1. of Definition 8 is satisfied since left-hand sides of equations in $\mathcal{E}$ are linear patterns according to Definition 9 item $i$. Item 2. is trivially satisfied, since left-hand sides of rules cannot be constructor terms. Regarding item 3., note first that since we are in a many-sorted setting, there are no non-trivial specializations. Furthermore, since we do not have any mutually recursive functions in $\mathcal{E}, \operatorname{root}\left(\left.\bar{r}\right|_{p}\right) \overline{\mathcal{E}} \operatorname{root}(\bar{l})$ implies $\operatorname{root}\left(\left.r\right|_{p}\right)=\operatorname{root}(l)$ for all rules $l \rightarrow r$ of $\mathcal{E}$ and all positions $p \in \operatorname{Pos}(r)$. Hence, in order to prove that $\mathcal{E}$ satisfies item 3. of Definition 8 it suffices to show that every rule $l \rightarrow r$ of $\mathcal{E}$ is $\operatorname{root}(l)$ argument decreasing. Thus, consider such a rule. According to Definition 9 is has the shape

$$
f_{i}\left(t_{1}, \ldots, t_{n_{i}}\right) \rightarrow C\left[f_{i}\left(u_{1}^{1}, \ldots, u_{n_{i}}^{1}\right) \ldots f_{i}\left(u_{1}^{k}, \ldots, u_{n_{i}}^{k}\right)\right]
$$

Since $\operatorname{stat}\left(f_{i}\right)=l e x$, we need to show that $\left(t_{1}, \ldots, t_{n_{i}}\right) \triangleright^{l e x}\left(v_{1}, \ldots, v_{n_{i}}\right)$ for every occurrence of a term of the shape $f_{i}\left(v_{1}, \ldots, v_{n_{i}}\right)$ in $r$. By definition the context $C$ does not contain terms rooted by $f_{i}$ (item $i i$ of Definition 9). Hence, consider the term $f_{i}\left(u_{1}^{j}, \ldots, u_{n_{i}}^{j}\right)$ for an arbitrary $1 \leq j \leq k$. By Definition 9 item iii.3, we have $\left(t_{1}, \ldots, t_{n_{i}}\right) \triangleright^{l e x}\left(u_{1}^{j}, \ldots, u_{n_{i}}^{j}\right)$. Now consider the immediate (proper) subterms of $f_{i}\left(u_{1}^{j}, \ldots, u_{n_{i}}^{j}\right)$. Again, by Definition 9 items $i i i .1$ and $i i i .2$, these terms are either terms over $\mathcal{T}\left(\Omega \cup\left\{f_{1}, \ldots, f_{i-1}, \mathcal{X}\right)\right.$ or are of the shape $f_{i}\left(v_{1}, \ldots, v_{n_{i}}\right)$ such that $\left(t_{1}, \ldots, t_{n_{i}}\right) \triangleright\left(v_{1}, \ldots, v_{n_{i}}\right)$, which on the one hand implies $\left(t_{1}, \ldots, t_{n_{i}}\right) \triangleright^{l e x}\left(v_{1}, \ldots, v_{n_{i}}\right)$ and on the other hand implies that $f_{i}\left(v_{1}, \ldots, v_{n_{i}}\right)$ does not contain a proper $f_{i}$-rooted subterm. Hence, $l \rightarrow r$ is $\operatorname{root}(l)$ argument decreasing and thus item 3. of Definition 8 is satisfied.

Finally, items 4 . and 5 . of Definition 8 are trivially satisfied, because $\mathcal{E}$ does not contain structural axioms.

## B Missing Proofs of Section 4

Theorem 3 (modularity of sort-decreasingness). Let $\mathcal{E}_{1}=\left(\Sigma_{1}, B_{0}^{1}, R_{1}\right)$ and $\mathcal{E}_{2}=\left(\Sigma_{1} \cup\right.$ $\left.\Sigma_{2}, B_{0}^{1} \cup B_{0}^{2}, R_{1} \cup R_{2}\right)$ be $O S$ theories where the $B_{0}^{i}$ s are $C$ or $A C$ axioms for both $i \in\{1,2\}$. If $\mathcal{E}_{1}$ and $\mathcal{E}_{2}^{\prime}=\left(\Sigma_{1} \cup \Sigma_{2}, B_{0}^{1} \cup B_{0}^{2}, R_{2}\right)$ are both sort-decreasing, then so is $\mathcal{E}_{2}$.
Proof. We need to show that $l s(l \theta) \geq l s(r \theta)$ for all rules $l \rightarrow r \in R_{1} \cup R_{2}$ and all specializations $\theta$. First, assume $l \rightarrow r \in R_{1}$. Then because $\Sigma_{2}$ introduces no new subsorts of sorts in $\Sigma_{1}$ (by Definition $10), l s(l \theta) \geq l s(r \theta)$ is implied by sort-decreasingness of $\mathcal{E}_{1}$. Second, if $l \rightarrow r \in R_{2}, l s(l \theta) \geq l s(r \theta)$ by sort decreasingness of $\mathcal{E}_{2}^{\prime}$.

Theorem 4 (Modularity of well-Founded Recursion). Let $\mathcal{E}_{1}=\left(\Sigma_{1}, B_{0}^{1}, R_{1}\right)$ and $\mathcal{E}_{2}=$ $\left(\Sigma_{1} \cup \Sigma_{2}, B_{0}^{1} \cup B_{0}^{2}, R_{1} \cup R_{2}\right)$ be OS theories such that $\mathcal{E}_{2}$ fairly extends $\mathcal{E}_{1}$ and the $B_{0}^{i}$ s are $C$ or $A C$ axioms for both $i \in\{1,2\}$. If $\mathcal{E}_{1}$ and $\mathcal{E}_{2}^{\prime}=\left(\Sigma_{1} \cup \Sigma_{2}, B_{0}^{1} \cup B_{0}^{2}, R_{2}\right)$ are well-founded recursive w.r.t. to functions stat ${ }^{1}$, stat ${ }_{a c}^{1}$ and stat ${ }^{2}$, stat ${ }_{a c}^{2}$ that are compatible, then so is $\mathcal{E}_{2}$.

Proof. We have to show that $\mathcal{E}_{2}=\left(\Sigma_{1} \cup \Sigma_{2}, B_{0}^{1} \cup B_{0}^{2}, R_{1} \cup R_{2}\right)$ is well-founded recursive. Let $\Sigma_{1}=\left(S_{1},<_{1}, F_{1}=\Omega_{1} \uplus \mathcal{D}_{1}\right)$ and $\Sigma_{2}=\left(S_{2},<_{2}, F_{2}=\Omega_{2} \uplus \mathcal{D}_{2}\right)$. We prove well-foundedness of $\mathcal{E}_{2}$ by looking at the rule of $R_{1} \cup R_{2}$. First, consider a rule $l \rightarrow r$ of $R_{1}$. Since the function symbols occurring in $l$ or the proper subterms of $l$ resp. $f l a t(l, \operatorname{root}(l))$ are from $\Omega_{1}$ if $l$ is a free or $C$, resp. an $A C$ symbol, they are also constructors in $\mathcal{E}_{2}$ since $\Omega_{2} \subseteq \Omega_{1} \cup \Omega_{2}$ and thus $l$ is a pattern in $\mathcal{E}_{2}$. Hence, if $r$ was a constructor term w.r.t. $\Sigma_{1}$, then it is also a constructor term w.r.t. $\Sigma_{1} \cup \Sigma_{2}$.

Moreover, consider a subterm $t$ of $r$ and a specialization $\theta$ where $\operatorname{root}(\overline{t \theta})-\overline{\mathcal{E}_{2}^{\prime}} \operatorname{root}(\overline{l \theta})$. We distinguish three possible cases according to the whether $\operatorname{root}(\overline{t \theta}) \vee \overline{\mathcal{E}_{1}} \operatorname{root}(\overline{l \theta})$ or not and whether $s t a t_{a c}(\operatorname{root}(l))$ is $s$ or $u s$.

- In case $\operatorname{root}(\overline{t \theta})-\overline{\mathcal{E}_{1}} \operatorname{root}(\overline{l \theta})$ we are done, because $\mathcal{E}_{1}$ is well-founded recursive and hence $\overline{l \theta} \rightarrow \overline{r \theta}$ is $\operatorname{root}(\overline{t \theta})$ argument decreasing.
- If $\operatorname{root}(\overline{t \theta}){ }_{\mathcal{E}_{1}} \operatorname{root}(\overline{l \theta})$ and $s t a t_{a c}(\operatorname{root}(l))=u s$, then either $\overline{l \theta} \rightarrow \overline{r \theta}$ is $\operatorname{root}(\overline{t \theta})$ is argument decreasing in which case we are done or $\operatorname{root}(t) \mathcal{E}_{1} \operatorname{root}(l)$ and thus we have $\operatorname{root}(t) \not \mathcal{E}_{2}^{\prime} \operatorname{root}(l)$ which is a contradiction to $\operatorname{root}(\overline{t \theta})-\overline{\mathcal{E}_{2}^{\prime}} \operatorname{root}(\overline{l \theta})$.
- Finally, assume that $\operatorname{root}(\overline{t \theta}) \overline{\mathcal{E}}_{1} \operatorname{root}(\overline{l \theta})$ and $\operatorname{stat}_{a c}(\operatorname{root}(l))=s$ (or $\operatorname{root}(l)$ is not an $A C$ symbol). There is a rule $l^{\prime} \rightarrow r^{\prime} \in R_{2}$ with $\operatorname{root}\left(\overline{l^{\prime} \theta}\right)=\operatorname{root}(\overline{t \theta})$. Hence, $l^{\prime}$ unifies in an ordersorted way with $\operatorname{root}(t)\left(x_{1}, \ldots, x_{n}\right)$ where the sort of $x_{i}=s_{i}$ and $\operatorname{root}(t): s_{1}, \ldots, s_{n} \rightarrow s \in \Sigma_{1}$. Hence, we get a contradiction to $\mathcal{E}_{2}$ being a fair extension of $\mathcal{E}_{1}$.

If $\operatorname{root}(l)$ is an $A C$ constructor (for some specialization) we additionally need to show that $\operatorname{root}\left(\left.l\right|_{p}\right) \not \mathcal{E}_{2} \operatorname{root}(l)$ for all positions $p \in \operatorname{Pos}_{\Sigma}(l), p>\epsilon$. We have $\operatorname{root}\left(\left.l\right|_{p}\right) \mathcal{E}_{1} \operatorname{root}(l)$, because $\mathcal{E}_{1}$ is well-founded recursive. If $\operatorname{root}\left(\left.l\right|_{p}\right) \mathcal{E}_{2} \operatorname{root}(l)$, then there is a rule $l^{\prime} \rightarrow r^{\prime}$ in $R_{2}$ such that $l^{\prime}$ and $\operatorname{root}\left(\left.l\right|_{p}\right)\left(x_{s_{1}}^{1}, \ldots, x_{s_{n}}^{n}\right)$ unify (order-sorted modulo axioms) where $\operatorname{root}\left(\left.l\right|_{p}\right): s_{1}, \ldots, s_{n} \rightarrow s \in \Sigma_{1}$ and thus we derive a contradiction to $\mathcal{E}_{2}$ being a fair extension of $\mathcal{E}_{1}$.

Now consider a rule $l \rightarrow r$ from $R_{2}$. Since $\mathcal{E}_{2}^{\prime}$ is well-founded recursive $l$ is a pattern or constructor term and $f l a t(l, \operatorname{root}(l))$ is a pattern in $\mathcal{E}_{2}$.

Now consider a subterm $t$ of $r$ and a specialization $\theta$ where $\operatorname{root}(\overline{t \theta})-\mathcal{E}_{1} \operatorname{root}(\overline{l \theta})$. We distinguish
 or $u s$.

- In case $\operatorname{root}(\overline{t \theta}){\overline{\mathcal{E}_{2}}}^{\prime} \operatorname{root}(\overline{l \theta})$ we are done, because $\mathcal{E}_{2}^{\prime}$ is well-founded recursive and hence $\overline{l \theta} \rightarrow \overline{r \theta}$ is $\operatorname{root}(\overline{t \theta})$ argument decreasing.
- If $\operatorname{root}(\overline{t \theta}){\overline{\mathcal{E}_{2}}}^{\prime} \operatorname{root}(\overline{l \theta}) \operatorname{stat}_{a c}(\operatorname{root}(l))=u s$, then either $\overline{l \theta} \rightarrow \overline{r \theta}$ is $\operatorname{root}(\overline{t \theta})$ argument decreasing in which case we are done or $\operatorname{root}(t) \not \mathcal{E}_{2}^{\prime} \operatorname{root}(t)$ and thus we have $\operatorname{root}(t) \not \mathcal{E}_{1} \operatorname{root}(l)$ which is a contradiction to $\operatorname{root}(\overline{t \theta})-\overline{\mathcal{E}_{1}} \operatorname{root}(\overline{l \theta})$.
- Finally, assume that $\operatorname{root}(\overline{t \theta}) \quad \operatorname{\mathcal {E}_{2}^{\prime }} \operatorname{root}(\overline{l \theta})$ and $\operatorname{stat}_{a c}(\operatorname{root}(l))=s($ or $\operatorname{root}(l)$ is not an $A C$ symbol). There is a rule $l^{\prime} \rightarrow r^{\prime} \in R_{1}$ with $\operatorname{root}\left(\overline{\left.r\right|_{q} ^{\prime} \theta}\right)=\operatorname{root}(\overline{l \theta})$ for some position $q$. Hence, $l$ unifies in an order-sorted way with $\operatorname{root}\left(\left.r^{\prime}\right|_{q}\right)\left(x_{1}, \ldots, x_{n}\right)$ where the sort of $x_{i}=s_{i}$ and $\operatorname{root}\left(\left.r^{\prime}\right|_{p}\right)$ is typed $\operatorname{root}\left(\left.r^{\prime}\right|_{p}\right): s_{1}, \ldots, s_{n} \rightarrow s \in \Sigma_{1}$. Hence, we get a contradiction to $\mathcal{E}_{2}$ being a fair extension of $\mathcal{E}_{1}$.

If $\operatorname{root}(l)$ is an $A C$ constructor (for some specialization) we additionally need to show that $\operatorname{root}\left(\left.l\right|_{p}\right) \not \mathcal{E}_{2} \operatorname{root}(l)$ for all positions $p \in \operatorname{Pos}_{\Sigma}(l), p>\epsilon$. We have $\operatorname{root}\left(\left.l\right|_{p}\right) \not \mathcal{E}_{2}^{\prime} \operatorname{root}(l)$, since $\mathcal{E}_{2}^{\prime}$ is well-founded recursive. If $\operatorname{root}\left(\left.l\right|_{p}\right) \mathcal{E}_{1} \operatorname{root}(l)$, then there exists a rule $l^{\prime} \rightarrow r^{\prime}$ in $R_{1}$ with $\operatorname{root}\left(l^{\prime}\right)=\operatorname{root}\left(\left.l\right|_{p}\right)$ and thus we get a contradiction to $\mathcal{E}_{2}$ being a fair extension of $\mathcal{E}_{1}$.

Regarding Item 4 in Definition 8, rules in $\mathcal{E}_{2}$ satisfy this property because since no subsorts of sorts present in $\Sigma_{1}$ are introduced, the possible specializations of rules are the same as for $\mathcal{E}_{1}$ and $\mathcal{E}_{2}$.

Finally, if $h \mathcal{E}_{2} g$ and $g \mathcal{E}_{2} h$, then either $h \mathcal{E}_{1} g$ and $g \mathcal{E}_{1} h$ or $h \mathcal{E}_{2}^{\prime} g$ and $g \mathcal{E}_{2}^{\prime} h$, and thus either both symbols are $A C$ or both are not $A C$.

Theorem 5 (MODULARITY OF CONFLUENCE). Let $\mathcal{E}_{1}=\left(\Sigma_{1}, B_{0}^{1}, R_{1}\right)$ and $\mathcal{E}_{2}=\left(\Sigma_{1} \cup \Sigma_{2}, B_{0}^{1} \cup\right.$ $B_{0}^{2}, R_{1} \cup R_{2}$ ) be $O S$ theories such that $\mathcal{E}_{2}$ fairly extends $\mathcal{E}_{1}$ and the $B_{0}^{i}$ s are $C$ or $A C$ axioms for both $i \in\{1,2\}$. Moreover, let $\mathcal{E}_{1}$ and $\mathcal{E}_{2}^{\prime}=\left(\Sigma_{1} \cup \Sigma_{2}, B_{0}^{1} \cup B_{0}^{2}, R_{2}\right)$ be well-founded recursive w.r.t. to functions stat ${ }^{1}$, stat ${ }_{a c}^{1}$ and stat ${ }^{2}$, stat ${ }_{a c}^{2}$ that are compatible. If $\mathcal{E}_{1}$ and $\mathcal{E}_{2}^{\prime}$ are confluent then so is $\mathcal{E}_{2}$.
Proof. Since $\mathcal{E}_{1}, \mathcal{E}_{2}^{\prime}$ and $\mathcal{E}_{2}$ are all terminating modulo the respective axioms according to Theorems 4 and 1 , confluence of either theory is equivalent to joinability of all critical pairs (modulo axioms). To prove confluence of $\mathcal{E}_{2}$ we thus consider critical pairs of $\mathcal{E}_{2}$. If the rules used for the critical pair are either both from $R_{1}$ or both from $R_{2}$, joinability follows from confluence of $\mathcal{E}_{1}$ resp. $\mathcal{E}_{2}$. Otherwise, we distinguish two cases, depending on the type of overlap of left-hand sides of rules the critical pair originate from.

- First, assume that a left-hand side $l$ of some rule of $R_{1}$ unifies (order-sorted modulo axioms) with a proper (non-variable) subterm $t$ of some lhs $l^{\prime}$ of a rule of $R_{2}$ with some unifier $\theta$. Since $l^{\prime}$ is a pattern in $\mathcal{E}_{2}^{\prime}, \operatorname{root}(t \theta)$ is a constructor in $\mathcal{E}_{2}^{\prime}$ and thus $\operatorname{root}(l \theta)$ is a constructor in $\mathcal{E}_{1}$, because $\operatorname{root}(t \theta)=\operatorname{root}(l \theta)$ and there are no new constructors of sorts of $S_{1}$ in $\mathcal{E}_{2}$ according to Definition 10. Hence, we get a contradiction to $\mathcal{E}_{2}$ being a fair extension of $\mathcal{E}_{1}$ since $\operatorname{root}(l)$ is a constructor and $l$ overlaps the left-hand side of a rule from $R_{2}$. Thus, there are no overlaps of this kind.
- Second, assume that a left-hand side $l$ of some rule of $R_{2}$ unifies (order-sorted modulo axioms) with a (non-variable and not necessarily proper) subterm $t$ of some lhs $l^{\prime}$ of a rule of $R_{1}$ with some unifier $\theta$. Let $\operatorname{root}(t \theta): s_{1}, \ldots, s_{n} \rightarrow s$ be a declaration of the operator $\operatorname{root}(t)$ in $\Sigma_{1}$. Since $t$ and $l$ unify, also $\operatorname{root}(t)\left(x_{s_{1}}^{1}, \ldots, x_{s_{n}}^{n}\right)$ and $l$ unify and we have a contradiction to $\mathcal{E}_{2}$ being a proper extension of $\mathcal{E}_{1}$. Hence, there are no overlaps of this kind as well.

Hence, all critical pairs of $\mathcal{E}_{2}$ are joinable and we deduce confluence from termination of $\mathcal{E}_{2}$.
Theorem 6 (Modularity of sufficient Completeness). Let $\mathcal{E}_{1}=\left(\Sigma_{1}, B_{0}^{1}, R_{1}\right)$ and $\mathcal{E}_{2}=$ $\left(\Sigma_{1} \cup \Sigma_{2}, B_{0}^{1} \cup B_{0}^{2}, R_{1} \cup R_{2}\right)$ be $O S$ theories ( $\left.\Sigma_{i}=\mathcal{D}_{i} \cup \Omega_{i}\right)$ such that $\mathcal{E}_{2}$ fairly extends $\mathcal{E}_{1}$ and the $B_{0}^{i} s$ are $C$ or $A C$ axioms for both $i \in\{1,2\}$. Moreover, let $\mathcal{E}_{1}$ and $\mathcal{E}_{2}^{\prime}=\left(\Sigma_{1} \cup \Sigma_{2}, B_{0}^{1} \cup B_{0}^{2}, R_{2}\right)$ be well-founded recursive w.r.t. to functions stat ${ }^{1}$, stat ${ }_{a c}^{1}$ and stat ${ }^{2}$, stat ${ }_{a c}^{2}$ that are compatible. If $\mathcal{E}_{1}$ is sufficiently complete and for every function $f: s_{1}, \ldots, s_{n} \rightarrow s \in \mathcal{D}_{2} \backslash \mathcal{D}_{1}$ and every ground substitution $\sigma$ that maps variables to irreducible constructor terms, $f\left(x_{s_{1}}^{1}, \ldots, x_{s_{n}}^{n}\right) \sigma$ is either $\mathcal{E}_{2}$ reducible or a constructor term (where $x_{s}$ is a variable of sort $s$ ), then $\mathcal{E}_{2}$ is sufficiently complete.
Proof. Assume towards a contradiction that $\mathcal{E}_{2}$ is not sufficiently complete. Then because of termination of $\mathcal{E}_{2}$ (which holds by Theorem 4 and Theorem 1), there exists a term ground $t$, that is not a constructor term and is $\mathcal{E}_{2}$-irreducible. Consider a (not necessarily proper) subterm $s$ of $t$, where $\operatorname{root}(s)$ is a defined symbol and every proper subterm of $s$ is a constructor term. If $\operatorname{root}(s) \in \Sigma_{1}$, then $s \in \mathcal{T}\left(\Sigma_{1}, V\right)$, because there are no constructors in $\Sigma_{2}$ of sorts of $\Sigma_{1}$ by Definition 10. Hence, we obtain a contradiction to sufficient completeness of $\mathcal{E}_{1}$ by $\mathcal{E}_{1}$-irreducibility of $s$.

Otherwise, $\operatorname{root}(s) \in \Sigma_{2} \backslash \Sigma_{1}$. Then $s$ is an instance of the term $\operatorname{root}(s)\left(x_{1}, \ldots, x_{n}\right)$ where $x_{i}$ is a variable of sort $s_{i}$ and $\operatorname{root}(s)$ is typed $\operatorname{root}(s): s_{1}, \ldots, s_{n} \rightarrow s$. Thus, we get a contradiction to $\mathcal{E}_{2}$-irreducibility of $s$.

## C Missing Proofs of Section 5

Lemma 6 (modularity of sufficient completeness). Under the above restrictions on the first typing of an associative operator $f$, the associativity equation $f(L, P), Q)=f(L, f(P, Q))$ is an
inductive consequence of the restricted associativity equation $f(f(E, N L), Q)=f(E, f(N L, Q))$. Likewise, under the second typing the associativity equation $f(L, f(P, Q))=f(f(L, P), Q)$ is an inductive consequence of the restricted associativity equation $f(Q, f(N L, E))=f(f(Q, N L), E))$.

Proof. The proof is by constructor-based structural induction. Without loss of generality we prove the result for the fist typing, which has a constructor declaration $f:$ Elt NeList $\rightarrow$ NeList [ctor] (the proof for the second typing is entirely similar). By assumption the only constructors of type NeList are nil, the above constructor for $f$, and whatever constructors may exist of sort Elt. These latter constructors may be ignored, since the canonical form of any term of sort List by the identity equations is either nil, or an element $E$, or a constructor term of the form $f(E, N L)$. By inducting on $L$ get three inductive subgoals: (i) $f(f(n i l, P), Q)=f(n i l, f(P, Q))$, (ii) $f(f(E, P), Q)=f(E, f(P, Q))$, and (iii) $f(f(f(E, N L), P), Q)=f(f(E, N L), f(P, Q))$. The proof of (i) is trivial. The proof of (ii) is straightforward by structural induction on $P$. Let us focus on proving (iii) under the induction hypotheses $f(f(E, P), Q)=f(E, f(P, Q))$ and $f(f(N L, P), Q)=f(N L, f(P, Q))$. To begin with, (iii) can be immediately simplified with the restricted associativity equation to: $f(f(E, f(N L, P)), Q)=f(E, f(N L, f(P, Q)))$. But this goal can then be discharged by applying the first and second induction hypotheses to simplify the left term to the right term of the equation.

[^0]:    * The first author has been supported by the Austrian Academy of Sciences under grant number 22.361 and by the Austrian Marshall Plan Foundation in the Marshall Plan Scholarship Program under grant number 154.265.20.3.2010. The second author has been supported by NSF Grants CNS 07-16638 and 09-04749, and CCF 09-05584.

[^1]:    ${ }^{3}$ This assumption makes the technical treatment simpler, but it does not involve loss of generality and does not have to be specified explicitly: we can always assume that a new top sort $[s]$ is added to each connected component so that a binary operator $f$ to which some axiom in $B$ apply is overloaded for the top sort as $f:[s][s] \longrightarrow[s]$. Maude adds these "kind" sorts $[s]$ automatically to any specification.
    ${ }^{4}$ Maude automatically checks the $B$-preregularity of a signature $\Sigma$ for any combination of associativity, commutativity and identity axioms (see [6, Chapter 22.2.5]).

[^2]:    ${ }^{5}$ The subscript 0 in $B_{0}$ indicates that only $C$ and $A C$ axioms are present. In Section 5 below also other combinations of $A, C$ and $I$ axioms will be considered.

[^3]:    ${ }^{6}$ But note that we can have $f: s_{1}, \ldots, s_{n} \rightarrow s \in \mathcal{D}$ and another $f: s_{1}^{\prime}, \ldots, s_{n}^{\prime} \rightarrow s^{\prime} \in \Omega$, as illustrated for $f=\underset{t \bar{u} ;}{ }$ - by our running example.
    ${ }^{7} A \triangleright^{t \bar{u} p} \bar{B}$ (where $\triangleright$ is the proper subterm relation of terms) for multisets $A$ and $B$ of terms means that $A=A^{\prime} \cup C, B=B^{\prime} \cup C, A^{\prime} \neq \emptyset$ and there is a (possibly partial) surjective mapping $\phi: A^{\prime} \rightarrow B^{\prime}$, such that $\phi(a)=b$ implies $a \triangleright b$.

[^4]:    ${ }^{8}$ The function statac determines for an $A C$ function symbol $f$ whether sorts are taken into account ( $s$ for sorted) or not (us for unsorted) when comparing labeled versions $f_{\Psi}, f_{\Psi^{\prime}}$ of this function in the $A C R P O$ we are going to use to prove termination of well-founded recursive theories (cf. Theorem 1 below).

[^5]:    ${ }^{9}$ Compatibility of two functions $f_{1}$ and $f_{2}$ here means that $f_{1}(a)=f_{2}(a)$ whenever $a \in \operatorname{Dom}\left(f_{1}\right) \cap$ $\operatorname{Dom}\left(f_{2}\right)$.

[^6]:    ${ }^{10}$ By adding a fresh top sort to each connected component as explained in Footnote 3, we only need to add a pair of identity rules $f(x, e) \rightarrow x$ and $f(e, x) \rightarrow x$, with $x$ of sort $[s]$, for each connected component $[s]$ involving such axioms.

[^7]:    ${ }^{11}$ The $R$ subscript refers to the rules $R$ of $\mathcal{E}$ and the $j$ subscript stands for "jump" because the rules model jumps from sorts to subsorts (cf. [25][Definition 4]).

[^8]:    ${ }^{12}$ The reason we cannot just use the plain number of such positions for the induction is that changing the labels of nested $A C$ symbols has to be done in one step.

[^9]:    $\overline{{ }^{13} \Sigma^{<f}}$ is the set of function symbols that are smaller than $f$ in the precedence $<$.
