Abstract. This paper deals with the restoration of images corrupted by a non-invertible or ill-conditioned linear transform and Poisson noise. Poisson data typically occur in imaging processes where the images are obtained by counting particles, e.g., photons, that hit the image support. By using the Anscombe transform, the Poisson noise can be approximated by an additive Gaussian noise with zero mean and unit variance. Then, the least squares difference between the Anscombe transformed corrupted image and the original image can be estimated by the number of observations. We use this information by considering an Anscombe transformed constrained model to restore the image. The advantage with respect to corresponding penalized approaches lies in the existence of a simple model for parameter estimation. We solve the constrained minimization problem by applying a primal-dual algorithm together with a projection onto the epigraph of a convex function related to the Anscombe transform. We show that this epigraphical projection can be efficiently computed by Newton's methods with an appropriate initialization. Numerical examples demonstrate the good performance of our approach, in particular, its close behaviour with respect to the I -divergence constrained model.

1 Introduction

The Poisson distribution exhibits a mean/variance relationship. This mean/variance dependence can be reduced by using variance-stabilizing transformations (VST), one of which is the *Anscombe transform* [1] defined as

$$T: [0, +\infty)^n \rightarrow (0, +\infty)^n: v = (v_i)_{1 \leq i \leq n} \mapsto 2 \left(\sqrt{v_i + \frac{3}{8}} \right)_{1 \leq i \leq n}.$$

It transforms Poisson noise to approximately Gaussian noise with zero-mean and unit variance. The Anscombe transform has been employed in order to solve inverse problems where one wants to recover an original signal $\bar{u} \in [0, +\infty)^m$ from observations

$$f = \mathcal{P}(H\bar{u}),$$

where \mathcal{P} denotes an independent Poisson noise corruption process and $H \in [0, +\infty)^{n \times m}$ is a linear degradation operator, e.g. a blur. Note that we consider images of size $M \times N$ columnwise reshaped as vectors of length $m = MN$.

In this context, one of the possible uses of the Anscombe transform is *i*) to transform the degraded observations f , *ii*) to apply a data recovery technique which is valid for an additive white zero-mean Gaussian model and *iii*) to apply an inverse transform to the so-recovered signal [7] (see also [18] for more recent developments). Note that this method appears mainly to be well-founded for denoising problems. When a linear degradation operator H is present, a better approach consists of adopting a variational framework [8, 13] where one minimizes a data fidelity term

$$u \mapsto \|T(Hu) - T(f)\|_2^2 \quad (1)$$

penalized by a (sum of) regularization term(s) serving to incorporate prior information about the sought signal \bar{u} . The approach is also closely related to a Maximum A Posteriori (MAP) estimate, where the function in (1) is substituted for the neg-log-likelihood of the Poisson noise, i.e., the I -divergence (generalized Kullback-Leibler divergence)

$$u \mapsto D(f, Hu) := \begin{cases} \langle \mathbf{1}_n, f \log \frac{f}{Hu} - f + Hu \rangle & \text{if } Hu > 0, \\ +\infty & \text{otherwise,} \end{cases}$$

where $\langle \cdot, \cdot \rangle$ denotes the standard Euclidean inner product and $\mathbf{1}_n$ denotes the vector consisting of n entries equal to 1 (see [14, 21]). One of the drawbacks of these penalized methods is that multiplicative constants weighting the regularization terms (the so-called regularization parameters) need to be set carefully, which may be a difficult task.

A way of circumventing this problem consists of adopting a constrained approach instead of a regularized one, by imposing that

$$\|T(Hu) - T(f)\|_2^2 \leq \tau \quad (2)$$

where $\tau \in [0, +\infty)$. Based on the statistical properties of the Anscombe transform and the law of large numbers, a consistent choice for the above bound is $\tau = n$, when the number of observations n is large. In this work, we will investigate such an approach by solving the following problem:

$$\underset{u \in C}{\text{minimize}} \quad \Phi(Lu) \quad \text{subject to} \quad \|T(Hu) - T(f)\|_2^2 \leq \tau, \quad (3)$$

where C is a nonempty closed convex subset of $[0, +\infty)^m$, $L \in \mathbb{R}^{q \times m}$, and $\Phi: \mathbb{R}^q \rightarrow (-\infty, +\infty]$ is a proper, lower-semicontinuous, convex function. A typical choice for C is the nonnegative orthant of \mathbb{R}^m . The classical Total Variation objective function [20] is obtained, as a special case, when Φ is an $\ell_{2,1}$ norm and L corresponds to a discrete gradient operator. Constrained models based on the I -divergence have been considered in [5, 22], where in the second paper special attention was paid to the relation between the parameters of the constrained

and the penalized problem via discrepancy principles. Note that recently penalized versus constrained problems in a rather general form were handled in [2]. In [9], the I -divergence constraint was replaced through a polyhedral approximation technique and an epigraphical projection method was applied to solve the problem. In this work, we will also take advantage of an epigraphical projection approach to solve the Anscombe constrained model (3) and we will show that the required epigraphical projections can be easily determined in this context. The structure of this paper is as follows: Section 2 recalls the notation. In Section 3 we determine the epigraphical projection for a function related to constraint (2) which plays a central role in the primal dual algorithms established in Section 4. In particular, we provide a good starting point for the involved Newton method. Numerical examples are presented in Section 5 emphasizing the good approximation of the I -divergence constrained approach achieved by our Anscombe constrained model. Finally, a summary of our contribution and some conclusions are given in Section 6.

2 Notation

Let $\Gamma_0(\mathbb{R}^n)$ denote the set of proper, lower-semicontinuous, convex functions mapping from \mathbb{R}^n to $(-\infty, +\infty]$. The *epigraph* of $\varphi \in \Gamma_0(\mathbb{R}^n)$ is the nonempty, closed, convex subset of \mathbb{R}^{n+1} defined as

$$\text{epi } \varphi := \{(v, \zeta) \in \mathbb{R}^n \times \mathbb{R} : \varphi(v) \leq \zeta\}.$$

For a nonempty, closed, convex set $C \subset \mathbb{R}^m$ we denote by $\iota_C \in \Gamma_0(\mathbb{R}^m)$ its *indicator function*

$$\iota_C(u) := \begin{cases} 0 & \text{if } u \in C, \\ +\infty & \text{otherwise,} \end{cases}$$

and by P_C the *orthogonal projector* onto C . Beyond epigraphs of functions from $\Gamma_0(\mathbb{R}^n)$ we will consider the half-space $V_\tau := \{\zeta \in \mathbb{R}^n : \langle \mathbf{1}_n, \zeta \rangle \leq \tau\}$. Using this notation and defining, for every $i \in \{1, \dots, n\}$,

$$\varphi_i: [0, +\infty) \rightarrow [0, +\infty): s \mapsto (2\sqrt{s} - (T(f))_i)^2,$$

problem (3) can be rewritten as

$$\underset{(u, \zeta) \in \mathbb{R}^m \times \mathbb{R}^n}{\text{minimize}} \quad \iota_C(u) + \Phi(Lu) + \sum_{i=1}^n \iota_{\text{epi } \varphi_i} \left((Hu)_i + \frac{3}{8}, \zeta_i \right) + \iota_{V_\tau}(\zeta). \quad (4)$$

Now one can choose a primal-dual splitting algorithm as those proposed in [4, 6, 11, 12, 23] to solve this problem. One step in all these algorithms consists of the orthogonal projections onto the epigraphs of φ_i for all $i \in \{1, \dots, n\}$ which is the topic of the next section.

3 Epigraphical Projection

In this section, we deal with the projection onto the epigraph of the function $\varphi \in \Gamma_0(\mathbb{R})$ defined as

$$\varphi(s) := \begin{cases} (2\sqrt{s} - z)^2 & \text{if } s \geq 0, \\ +\infty & \text{otherwise,} \end{cases} \quad (5)$$

where $z > 0$, see Fig. 1.

Fig. 1. The epigraph of φ for $z = 3$ and the epigraphical projection $P_{\text{epi } \varphi}(x, \zeta)$ of some point (x, ζ) .

Proposition 1. Let φ be defined by (5) with $z > 0$. Then the epigraphical projection of $(x, \zeta) \in \mathbb{R}^2$ is given by

$$P_{\text{epi } \varphi}(x, \zeta) = \begin{cases} (\max\{x, 0\}, \zeta) & \text{if } (\max\{x, 0\}, \zeta) \in \text{epi } \varphi, \\ \left(\left(\frac{t_+ + z}{2} \right)^2, t_+^2 \right) & \text{if } 4x \geq z^2, \\ \left(\left(\frac{t_- + z}{2} \right)^2, t_-^2 \right) & \text{if } 4x < z^2, \end{cases}$$

where t_+ , resp. t_- is the unique root in $[0, +\infty)$, resp. in $(-z, 0)$ of the cubic polynomial

$$p: t \mapsto 17t^3 + 3zt^2 + (3z^2 - 16\zeta - 4x)t + z(z^2 - 4x). \quad (6)$$

Proof. The function φ fulfills $\varphi(0) = z^2$ and

$$\varphi'(s) = 4 - \frac{2z}{\sqrt{s}} \begin{cases} < 0 & \text{if } 0 < s < \frac{z^2}{4}, \\ = 0 & \text{if } s = \frac{z^2}{4}, \\ > 0 & \text{if } s > \frac{z^2}{4} \end{cases}$$

and therefore $\lim_{\substack{s \rightarrow 0 \\ s > 0}} \varphi'(s) = -\infty$. Thus, if $x \leq 0$ and $\zeta \geq z^2$, then $P_{\text{epi } \varphi}(x, \zeta) = (0, \zeta)$. In addition, if $(x, \zeta) \in \text{epi } \varphi$, then $P_{\text{epi } \varphi}(x, \zeta) = (x, \zeta)$.

We consider the remaining cases when $(\max\{x, 0\}, \zeta) \notin \text{epi } \varphi$. The tangent vector of the curve associated with the graph of φ reads $(1, \varphi'(s))$, $s > 0$. The uniquely determined orthogonal projection $(\hat{x}, \hat{\zeta}) := P_{\text{epi } \varphi}(x, \zeta)$ has to satisfy

$$\begin{pmatrix} x \\ \zeta \end{pmatrix} - \begin{pmatrix} \hat{x} \\ \hat{\zeta} \end{pmatrix} \perp \begin{pmatrix} 1 \\ \varphi'(\hat{x}) \end{pmatrix} \quad \text{and} \quad \hat{\zeta} = \varphi(\hat{x}), \quad \hat{x} > 0 \quad (7)$$

which leads to

$$0 = (x - \hat{x})\sqrt{\hat{x}} + 2 \left(\zeta - (2\sqrt{\hat{x}} - z)^2 \right) (2\sqrt{\hat{x}} - z), \quad \hat{x} > 0.$$

Substituting $\hat{t} := 2\sqrt{\hat{x}} - z > -z$, this can be rewritten as

$$0 = 17\hat{t}^3 + 3z\hat{t}^2 + (3z^2 - 16\zeta - 4x)\hat{t} + z(z^2 - 4x) = p(\hat{t}), \quad \hat{t} > -z.$$

Conversely, if $\hat{t} > -z$ is a root of the polynomial p in (6), then $\hat{x} = \left(\frac{\hat{t}+z}{2}\right)^2$ fulfills (7). When $x \geq z^2/4$ then also $\hat{x} \geq z^2/4$ (see Fig. 1), thus we are interested in the restriction of φ to $[z^2/4, +\infty)$ i.e., the nonnegative roots of p . The restriction of φ to $[z^2/4, +\infty)$ is convex, monotonically increasing, and $(x, \zeta) \notin \text{epi } \varphi$. Hence, there is a unique point $(\hat{x}, \hat{\zeta})$ on its graph that satisfies (7), i.e., p has a unique root in $[0, +\infty)$. Analogously, when $x < z^2/4$ then also $\hat{x} < z^2/4$, thus we are interested in the restriction of φ to $[0, z^2/4)$ i.e., the roots of p in the interval $(-z, 0)$. The restriction of φ to $[0, z^2/4)$ is convex and monotonically decreasing, and the uniqueness of the root follows by the same arguments. Finally, it can be noticed that $\hat{\zeta} = \varphi\left(\left(\frac{\hat{t}+z}{2}\right)^2\right) = \hat{t}^2$ since $\hat{t} > -z$, which completes the proof. \square

The next proposition states that the root t_+ , resp. t_- , of polynomial p can be computed efficiently by Newton's method with initial value $t_0 := 2\sqrt{\max\{x, 0\}} - z$. Indeed, we have seen in our numerical examples that t_0 is a very good starting point.

Proposition 2. *Let $(\max\{x, 0\}, \zeta) \notin \text{epi } \varphi$ and $t_0 := 2\sqrt{\max\{x, 0\}} - z$. Let the polynomial p be defined by (6). Then the Newton method for finding a zero of p with initial value t_0 converges (after a finite number of steps) monotonically to the root t_+ if $4x \geq z^2$, resp., t_- if $4x < z^2$.*

Proof. 1. First we show that

- i) $p(t_0)p(0) \leq 0$,
- ii) $p'(t_0) > 0$,

where equality in i) holds true iff $4x = z^2$.

If $x < 0$, then $t_0 = -z$ and consequently, since $(0, \zeta) \notin \text{epi } \varphi$, i.e., $z^2 > \zeta$, we obtain: $p(0) = z(z^2 - 4x) > 0$ and $p(t_0) = p(-z) = 16z(\zeta - z^2) < 0$, which proves i). Further, since $p': t \mapsto 51t^2 + 6zt + 3z^2 - 4x - 16\zeta$, we obtain

$$p'(t_0) = p'(-z) = 48z^2 - 16\zeta - 4x \geq 16(4z^2 - \zeta) > 0.$$

If $x \geq 0$, then $t_0 = 2\sqrt{x} - z$. Consequently, we have $p(0) = -z(z + 2\sqrt{x})t_0$ and

$$p(t_0) = 17t_0^3 + 2zt_0^2 + (3z^2 - 16\zeta - 4x)t_0 + (t_0^2 + z^2 - 4x)z = 16t_0(t_0^2 - \zeta).$$

Since $(x, \zeta) \notin \text{epi } \varphi$, i.e., $t_0^2 > \zeta$ we conclude that i) holds true. Finally ii) follows by

$$p'(t_0) = 51t_0^2 + 6zt_0 + 3z^2 - 16\zeta - 4x = 8(6t_0^2 - 2\zeta + x) = 16(t_0^2 - \zeta) + 8(4t_0^2 + x) > 0.$$

Since, in both cases, $p(t_0) \neq 0$, equality arises in i) iff $p(0) = 0$ i.e. $4x = z^2$.

2. The following result is well-known, see, e.g., [15, Theorem 18.3]: Newton's method for finding the unique root of a differentiable, convex, strictly increasing function on an interval converges monotonically if we start at the right endpoint of the interval. There is an analogue result for concave functions.

3. Since $p'' : t \mapsto 6(17t + z)$, p is convex on $[-\frac{z}{17}, +\infty)$ and concave on $(-\infty, -\frac{z}{17}]$.

3.1 Let $t_0 > 0$ which implies $4x - z^2 > 0$. Then $p(0) < 0$ and, according to Part 1i), $p(t_0) > 0$. Hence, by Proposition 1, t_+ is the unique root of p in $(0, t_0)$. Since p is continuous, $p(t_+) = 0$ and $p(t_0) > 0$, we necessarily have $p'(t_+) \geq 0$ (otherwise there would exist another root of p on (t_+, t_0)). Thus, since p is strictly convex, it is strictly monotone increasing on $[t_+, t_0]$ and we can invoke the argument in Part 2 of the proof.

3.2 Let $t_0 < 0$ which implies $4x - z^2 < 0$. Then, $p(0) > 0$ and $p(t_0) < 0$ and by Proposition 1 we know that $t_- \in (t_0, 0)$ is the unique root of p in $(-z, 0)$. If $t_- \leq -\frac{z}{17}$, then we are done by similar arguments as in 3.1 for concave functions. It remains to study the case when $t_- > -\frac{z}{17}$.

If $t_0 > -\frac{z}{17}$, then we know by the strict convexity of p on $[t_0, +\infty)$ that p' is strictly increasing on this interval and by Part 1ii) we further have $p'(t) > p'(t_0) > 0$ for every $t > t_0$. Thus, p itself is strictly increasing on $[t_0, +\infty)$. Consequently, one Newton step with initialization t_0 generates $t_1 = t_0 - p(t_0)/p'(t_0)$ and the convexity inequality $p(t_1) \geq p(t_0) + p'(t_0)(t_1 - t_0)$ shows that $p(t_1) \geq 0$. We thus are in the setting of Part 2 and the method converges monotonically. Finally, let $t_0 \leq -\frac{z}{17}$ so that

$$4x \leq \left(\frac{16}{17}\right)^2 z^2. \quad (8)$$

Since we must have $p(-\frac{z}{17}) < 0$, a straightforward calculation yields

$$p\left(-\frac{z}{17}\right) = \frac{2z}{17} \left(\frac{z^2}{17} + 7z^2 + 8\zeta - 32x\right) < 0 \Leftrightarrow 8\zeta < 32x - \frac{z^2}{17} - 7z^2. \quad (9)$$

We shall now prove that $p'(t) > 0$ for all $t \in \mathbb{R}$, so that p is strictly increasing. Since p' is a quadratic polynomial with minimum at $-\frac{z}{17}$, we have only to show that $p'(-\frac{z}{17}) = 2\left(\frac{24}{17}z^2 - 8\zeta - 2x\right) > 0$. Plugging in (8) and (9), we indeed obtain

$$\frac{1}{2}p'\left(-\frac{z}{17}\right) > \frac{24}{17}z^2 - 34x + \frac{z^2}{17} + 7z^2 > \frac{25}{17}z^2 - \frac{128}{17}z^2 + 7z^2 = \frac{16}{17}z^2 > 0.$$

The sequence $(t_k)_{k \in \mathbb{N}}$ generated by Newton's algorithm is such that there exists $k_0 \in \mathbb{N} \setminus \{0\}$ such that $t_{k_0} \geq t_-$. Otherwise, $(t_k)_{k \in \mathbb{N}}$ would be an increasing sequence which would necessarily converge to t_- and there would exist $k_1 \in \mathbb{N}$ such that p is convex over $[t_{k_1}, +\infty[$. Then, we would have $p(t_{k_1+1}) \geq 0$. Thus, after a finite number of steps, the algorithm arrives at $t_{k_0} \geq t_-$ and we can apply Part 2 of the proof.

3.3 Let $t_0 = 0$ which implies $4z - t^2 = 0$. Then, we get $t_+ = t_0$. \square

4 Primal-Dual Algorithms

We can apply the projection onto the epigraph of φ in combination with any primal-dual algorithm proposed in [4, 6, 11, 12, 23] or an alternating direction method of multipliers. For example, we use here the **primal-dual hybrid gradient** algorithm from [6, 19] with an extrapolation (**modification**) of the dual variable which will be designated by PDHGMp. Based on the following reformulation of (4),

$$\begin{aligned} & \underset{(u, \zeta), (v_1, v_2, \eta)}{\text{minimize}} && \iota_C(u) + \iota_{V_\tau}(\zeta) + \Phi(v_2) + \sum_{i=1}^n \iota_{\text{epi } \varphi_i}(v_{1,i}, \eta_i) \\ & \text{subject to} && \begin{pmatrix} H & 0 \\ L & 0 \\ 0 & I \end{pmatrix} \begin{pmatrix} u \\ \zeta \end{pmatrix} + \begin{pmatrix} 3/8 \\ 0 \\ 0 \end{pmatrix} = \begin{pmatrix} v_1 \\ v_2 \\ \eta \end{pmatrix}, \end{aligned} \quad (10)$$

this algorithm reads:

Algorithm 1 (PDHGMp for solving the Anscombe constrained problem)

Initialization: $u^{(0)}, \zeta^{(0)}, (p_j^{(0)})_{1 \leq j \leq 3} = (\bar{p}_j^{(0)})_{1 \leq j \leq 3}$, $\theta \in (0, 1]$, $(\rho, \sigma) \in (0, +\infty)^2$ with $\rho\sigma < 1/\max\{1, \|H^*H + L^*L\|_2\}$

For $k = 0, 1, \dots$ repeat until a stopping criterion is reached

1. $u^{(k+1)} = P_C \left(u^{(k)} - \sigma\rho \left(H^* \bar{p}_1^{(k)} + L^* \bar{p}_2^{(k)} \right) \right)$
2. $\zeta^{(k+1)} = P_{V_\tau} \left(\zeta^{(k)} - \sigma\rho \bar{p}_3^{(k)} \right)$
3. $(v_{1,i}^{(k+1)}, \eta_i^{(k+1)}) = P_{\text{epi } \varphi_i} \left(p_{1,i}^{(k)} + (Hu^{(k+1)})_i + 3/8, p_{3,i}^{(k)} + \zeta_i^{(k+1)} \right)$, $i = 1, \dots, n$
4. $v_2^{(k+1)} = \text{prox}_{\sigma^{-1}\Phi}(p_2^{(k)} + Lu^{(k+1)})$
5. $p_1^{(k+1)} = p_1^{(k)} + Hu^{(k+1)} + 3/8 - v_1^{(k+1)}$
6. $p_2^{(k+1)} = p_2^{(k)} + Lu^{(k+1)} - v_2^{(k+1)}$
7. $p_3^{(k+1)} = p_3^{(k)} + \zeta^{(k+1)} - \eta^{(k+1)}$
8. $\bar{p}_j^{(k+1)} = p_j^{(k+1)} + \theta(p_j^{(k+1)} - p_j^{(k)})$, $j = 1, 2, 3$.

The projection in step 1 is quite simple if C is the nonnegative orthant of \mathbb{R}^m . Step 3 requires the epigraphical projections discussed in the previous section, Step 4 can be performed by coupled soft shrinkage with threshold σ^{-1} if we use the $\ell_{2,1}$ -norm. The other steps can be computed in a straightforward way.

We will compare this algorithm with PDHGMP applied to the I -divergence constrained problem

$$\underset{u \in \mathcal{C}}{\text{minimize}} \quad \Phi(Lu) \quad \text{subject to} \quad D(f, Hu) \leq \tau_I \quad (11)$$

using a similar splitting to (10) but without the extra-variables ζ and η :

Algorithm 2 (PDHGMP for solving the I -divergence constrained problem)

Initialization: $u^{(0)}, (p_j^{(0)})_{1 \leq j \leq 2} = (\bar{p}_j^{(0)})_{1 \leq j \leq 2}$, $\theta \in (0, 1]$, $(\rho, \sigma) \in (0, +\infty)^2$ with $\rho\sigma < 1/\|H^*H + L^*L\|_2$

For $k = 0, 1, \dots$ repeat until a stopping criteria is reached

1. Step 1 of Algorithm 1
2. $\underset{v_1}{\text{minimize}} \|v_1 - (p_1^{(k)} + Hu^{(k+1)})\|_2^2$ subject to $D(f, v_1) \leq \tau_I$ as in [22].
3. - 5. Steps 4. - 6. of Algorithm 1
6. $\bar{p}_j^{(k+1)} = p_j^{(k+1)} + \theta(p_j^{(k+1)} - p_j^{(k)})$, $j = 1, 2$.

In [24] (see also [3]) statistical arguments were used to show that $\tau_I = \frac{1}{2}n$ is a good estimate in case of moderate Poisson noise. In [5] this estimate was improved in case f has many zero components.

5 Numerical Examples

In this section, we demonstrate the performance of our algorithm by numerical examples implemented in MATLAB (Intel Core i7-870 Processor with 8M Cache, 2.93 GHz, 8 GB physical memory). We have tested the two original images \bar{u} , namely 'cameraman' (256×256) and 'brain' (184×140), depicted in Fig. 2 and denoted by B1, resp. B2 in the following.

Fig. 2. Original images 'cameraman' (left) and phantom of a brain image (right).

The images were blurred by a matrix H corresponding to a Gaussian kernel with standard deviation 1.3 and mirrored boundary (we have then $m = n$). Their gray values are interpreted as photon counts in the range $[0, \nu]$, where

	$D(f, H\bar{u})/n$	$\ T(H\bar{u}) - T(f)\ _2^2/n$	PSNR	MAE
B1 ₁₀₀	0.5075	1.0086	20.58	66.41e-3
B1 ₆₀₀	0.5020	1.0034	23.38	41.59e-3
B1 ₁₂₀₀	0.5018	1.0039	23.79	37.17e-3
B1 ₂₀₀₀	0.4979	0.9960	23.97	34.87e-3
B1 ₃₀₀₀	0.4994	0.9989	24.06	33.58e-3
B2 ₁₀₀	0.4954	0.8866	18.34	82.45e-3
B2 ₆₀₀	0.5131	1.0004	20.17	61.01e-3
B2 ₁₂₀₀	0.5122	1.0178	20.37	57.90e-3
B2 ₂₀₀₀	0.5063	1.0085	20.49	56.02e-3
B2 ₃₀₀₀	0.4956	0.9899	20.52	55.16e-3

Table 1. The original values of $D(f, H\bar{u})/n$, $\|T(H\bar{u}) - T(f)\|_2^2/n$ and PSNR, MAE of f .

ν is the intensity of the image. We tested $\nu = 100, 600, 1200, 2000, 3000$ and denoted the blurred, noisy images by B1 $_{\nu}$ and B2 $_{\nu}$. In order to synthetically add Poisson noise to the noise-free image, we applied the MATLAB routine `imnoise(X, 'poisson')`. For a quantitative comparison of the images, we computed the peak signal to noise ratio (PSNR) and the (MAE) defined by $\text{PSNR} = 10 \log_{10} \frac{|\max \bar{u} - \min \bar{u}|^2}{\frac{1}{n} \|u - \bar{u}\|_2^2}$, and $\text{MAE} = \frac{1}{n\nu} \|\bar{u} - u\|_1$. The 'true' constraints between the blurred, noisy image f and the original image \bar{u} are given in Table 1. As can be seen, the estimates $\tau_I = n/2$ and $\tau = n$ are good approximations of the true constraints $D(f, H\bar{u})$ and $\|T(H\bar{u}) - T(f)\|_2^2$.

We computed a minimizer of our functional (3) with $C = [0, +\infty)^n$, the $\ell_{2,1}$ -norm for Φ , and the discrete gradient operator L ($q = 2n$) by using Algorithm 1 with $\tau = n$. We compared the result with the I -divergence constrained approach (11) and Algorithm 2 with $\tau_I = n/2$. The parameters σ and ρ appearing in PDHGMp (in this setting convergence is theoretically guaranteed for $\sigma\rho < 1/9$) are fitted such that the algorithms give (up to two digits after the comma) the same PSNR, MAE and TV-norm (times 10^5 or 10^6) after 1000 iterations as after 100000 iterations. In the I -divergence constrained approach with the brain data, we stopped after 5000 iterations. Furthermore, we have chosen $\theta = 1$. Fig. 3 shows the restoration results for B1₁₂₀₀ and Fig. 4 for B2₁₂₀₀.

Fig. 3. Result for the 'cameraman' image B1₁₂₀₀ corresponding to Table 3. Corrupted image (left), restoration result by the Anscombe constrained model and Alg. 1 (middle), difference image between the middle image and the one recovered by I -divergence constrained model and Alg. 2 (right). The gray values in the difference image are between -10 and 10, while the image values were scaled up to 1200.

Table 2. Results of Algorithms 1 and 2 with $\tau = n$ and $\tau_I = \frac{n}{2}$.

Fig. 4. Result for the 'brain' image B2₁₂₀₀ corresponding to Table 3. Corrupted image (left), restoration result by the Anscombe constrained model and Alg. 1 (middle), difference image between the middle image and the one recovered by the I -divergence constrained model and Alg. 2 (right). The gray values in the difference image are between -15 and 15, while the image values were scaled up to 1200.

Table 2 summarizes the results for the different intensities. As expected, we observe that the outcomes of the two algorithms are very similar. More precisely, if u_A , resp. u_I denotes the output of the restoration procedure with Anscombe, resp. I -divergence constraints, then we get for image B1 that $\|u_A - u_I\|_2 / (\nu\sqrt{n})$ ranges from 0.004 to $1.74e-4$ and $\max |u_A - u_I| / \nu$ from 0.0612 to 0.0031 for the different noise levels.

Finally, Table 3 compares Algorithms 1 and 2 for different constraints τ and τ_I and a central part of the cameraman of size 130×130 with $\nu = 3000$ after 1000 iterations.

6 Summary and Conclusions

We have considered a constrained restoration model for images corrupted by a linear transform and Poisson noise by making use of the Anscombe transform.

Table 3. Results of Algorithms 1 and 2 on a part of B1₃₀₀₀ for different constraining parameters $\tau = \text{scale} \cdot n$ and $\tau_I = \text{scale} \cdot \frac{n}{2}$. The optimal scale is computed as in Table 1.

In contrast with penalized approaches, a main advantage of the proposed one is that it makes it possible to employ a simple estimate for the model parameter. We have provided proximal algorithms to find a minimizer of the model, which are based on epigraphical projections, and we have shown that the performance is similar to a recently introduced I -divergence constrained model. Future research directions include the following: *i*) replacing or combining the discrete gradient operator L with other ones (discrete higher order operators, nonlocal means, wavelet-like transforms) and handling other problems than deblurring ones, *ii*) considering convex optimization problems involving multiple constraints for which the epigraphical projection approach may be quite efficient, see [10], *iii*) restoring images with Poisson+Gauss noise, see [16, 17], and *iv*) finding numerically efficient methods to map the constraint bound to the parameter of the corresponding penalized functional.
