Abstract

Background: SARS-CoV-2 caused one of the most devastating pandemics in the recent history of mankind. Due to various countermeasures, including lock-downs, wearing masks, and increased hygiene, the virus has been controlled in some parts of the world. More recently, the availability of vaccines, based on RNA or adenoviruses, has greatly added to our ability to keep the virus at bay; again, however, in some parts of the world only. While available vaccines are effective, it would be desirable to also have more classical vaccines at hand for the future. Key feature of vaccines for long-term control of SARS-CoV-2 would be inexpensive production at large scale, ability to make multiple booster injections, and long-term stability at 4°C.

Methods: Here, we describe such a vaccine candidate, consisting of the SARS-CoV-2 receptor-binding motif (RBM) grafted genetically onto the surface of the immunologically optimized cucumber mosaic virus, called CuMV_{TT}-RBM.

Results: Using bacterial fermentation and continuous flow centrifugation for purification, the yield of the production process is estimated to be >2.5 million doses per 1000-litre fermenter run. We demonstrate that the candidate vaccine is highly immunogenic in mice and rabbits and induces more high avidity antibodies compared to convalescent human sera. The induced antibodies are more cross-reactive to mutant RBDs of variants of concern (VoC). Furthermore, antibody responses are neutralizing and long-lived. In addition, the vaccine candidate was stable for at least 14 months at 4°C.

Conclusion: Thus, the here presented VLP-based vaccine may be a good candidate for use as conventional vaccine in the long term.

KEYWORDS

COVID-19, SARS-CoV-2, vaccine, virus-like particles

**GRAPHICAL ABSTRACT**

In this study, we describe a novel conventional COVID-19 vaccine that consists of the RBM of SARS-CoV-2 genetically grafted onto the surface of our optimized cucumber-mosaic virus-like particles. We demonstrate that the vaccine candidate (mCuMV_{TT}-RBM) is highly immunogenic in mice and rabbits, can efficiently neutralize SARS-CoV-2, and is stable and highly scalable. The induced antibodies show cross-reactivity with VoC.

1 | INTRODUCTION

Since the outbreak of the global pandemic caused by SARS-CoV-2, WHO has reported ~170 million confirmed cases by 3 June 2021 including ~3.5 million deaths (WHO, 3 June 2021). The pandemic has put a heavy toll on public health systems and world's economy. To limit the damage, efforts have been directed toward vaccine development. On 12th May 2021 around one billion doses of different vaccines have been administered worldwide (WHO, 12th May 2021). Although SARS-CoV-2 causes mostly mild symptoms such as coughing, fever and breathlessness, symptoms may become much more severe, in particular in elderly people and people with chronic diseases which may develop to severe pneumonia and other symptoms including organ failure and death.^{1,2} SARS-CoV-2 has a lower fatality rate (2.3%) in comparison with SARS (9.5%) and MERS (34.4%).³ However, it transmits much more readily, mostly because non-symptomatic and pre-symptomatic individuals can spread the virus. Thus, while MERS-CoV and SARS-CoV outbreaks have been sporadic and geographically restricted, SARS-CoV-2 has rapidly spread around the world^{4,5}.

The positive-sense ssRNA SARS-CoV-2 virus has a genome of about 29,700 nucleotides with 79.5% identity to SARS-CoV-1. Its genome encodes four main structural proteins; spike protein, membrane protein, nucleocapsid protein, and the envelope protein^{6,7}. SARS-CoV-2 binds to angiotensin-converting enzyme 2 (ACE2) via the (receptor-binding domain) RBD of its spike protein that protrudes from the viral envelope. Interaction of RBD with ACE2 is the first step in a cascade of events leading to viral entry and ultimately replication⁸. Neutralizing antibodies against SARS-CoV-2 are mostly targeting the RBD of the spike protein. Within RBD, the receptor-binding motif (RBM) is of particular importance as it directly interacts with ACE2⁹. Interestingly, RBM shows no glycosylation or other post-translational modifications and therefore is well suited for production in bacterial expression systems¹¹.

Vaccines are the most reliable, cost-effective, and efficient strategy to prevent infectious diseases. Vaccine candidates must induce sufficient quantities of high-affinity antibodies to neutralize the invading virus. Since the initiation of the pandemic, a full spectrum of vaccine types has been tested in preclinical and clinical trials. Vaccine platforms employed mRNA, DNA, viral vectors, inactivated

or live-attenuated virus^{10,12}, and recombinant proteins. The full length of spike protein, RBD, S1 subunit, fusion peptide (FP), and the N-terminal domain (NTD) of the spike protein have been targeted by vaccines that are licensed or undergoing development^{4,13}.

Virus-like particles (VLPs) represent one of the conventional vaccine platforms in the sense that there are globally marketed VLP-based products, for example, hepatitis B virus (HBV) and human papilloma virus (HPV) vaccines have demonstrated the clinical usefulness of this modality. VLPs consist of viral structural proteins that upon recombinant expression, self-assemble into icosahedral or rarely helical particles¹⁴. Recently, we have developed an immunologically optimized VLP platform based on the cucumber mosaic virus (CuMV_{TT}-VLPs)¹⁵. CuMV_{TT}-VLPs incorporate a universal T-cell epitope derived from tetanus toxin (TT)¹⁶. The newly developed platform enhances the interaction between T helper (T_H) cells and B cells, and is expected to improve responses in elderly individuals who are often less reactive to vaccines. This is supported by the fact that pre-existing immunity to the chosen TT epitope is very broad in humans (and animals) as the peptide binds to essentially all HLA-DR molecules and most people have been immunized many times against TT. In addition, CuMV_{TT}-VLPs are packaged with bacterial RNA which is a ligand for toll-like receptor (TLR) 7 and 8 and serves as a potent natural adjuvant^{16,17}. By displaying antigens on CuMV_{TT}-VLPs, it was possible to induce high levels of antigen-specific antibodies in mice, rats, cats, dogs, and horses and treat diseases such as atopic dermatitis in dogs or insect bite hypersensitivity in horses^{18,19}.

In the current study, we have designed and developed a scalable and immunogenic VLP-based COVID-19 vaccine by genetically fusing the RBM of the spike protein from SARS-CoV-2 into CuMV_{TT}-VLPs. The data show that this vaccine is highly immunogenic and capable of inducing both RBD-specific IgG and IgA antibodies as well as a strong viral neutralizing antibody response. Furthermore, the vaccine production process is highly scalable, potentially allowing the production of millions of doses in a single 1000L bacterial fermenter run.

2 | MATERIALS AND METHODS

2.1 | Mosaic CuMV_{TT}-RBM vaccine production, purification, and analysis

For expression and purification of mosaic CuMV_{TT}-RBM (m CuMV_{TT}-RBM), *E. coli* C2566 (New England Biolabs, USA) competent cells were transformed with the plasmid pETDu-CMVB3d-nCoV-M-CMV_{TT} (construction details are summarized in Supplementary data 1).

After selection of clones with the highest expression level of target proteins, *E. coli* culture was grown in 100 ml of 2TY medium (1.6% trypton, 1% yeast extract, 0.5% NaCl, 0.1% glucose) containing ampicillin (100 mg/l) on an orbital shaker at 30°C to the OD₆₀₀ value of 0.8–1.0. Then, the cells were induced with 0.2mM IPTG, and the medium was supplemented with 5mM MgCl₂. Incubation was continued

on the rotary shaker (200 rpm, 20°C, 18h). The resulting biomass was collected by low-speed centrifugation and was frozen at –20°C. To disrupt the cells, the biomass was resuspended 10 ml of buffer (20mM Tris, 5mM EDTA, 5mM Et-SH, 5% glycerol, 10% sucrose, pH 8.0) and further treated with ultrasound (Hielscher 200, power 70%, pulse 50%, 16min) on ice. Then, 0.5% Triton X-100 was added and the solution was rotated at 10 rpm ON at 4°C without centrifugation. The solution was then clarified for 10min at 10000 rpm (rotor: F-34–6–38 Eppendorf), and the pellet was discarded. The soluble fraction was loaded on the top of the sucrose gradient (20–60%; in buffer containing 20mM Tris, 2mM EDTA, 5% glycerol, 0.5% TX-100, pH 8.0) and centrifuged in Beckman SW32 rotor for 6h at 25500 rpm at 18°C. The gradient fractions^{6m} were then removed from the bottom of the 38 ml tube. The CuMV VLP containing fraction (40 and 50% sucrose, pooled) was diluted 1:1 with buffer (20mM Tris, 2mM EDTA, 5% glycerol, pH 8.0). The VLPs were sedimented using Type 70 rotor (Beckman, 50000 rpm, 4h, 4°C). Then, the pellet was dissolved ON in 4 ml of 20mM Tris, 2mM EDTA at 4°C. The solution was clarified by centrifugation (5min, 14000 rpm), the clarified solution overlaid on top of the 30% sucrose “cushion” solution in 20mM Tris, 2mM EDTA, 0.5% TX-100, pH 8.0. The VLPs were sedimented using Beckman TLA100.3 rotor (72000 rpm, 60min, 4°C). The pellet was solubilized in 2 ml of 20mM Tris, 2mM EDTA, and clarified again by centrifugation (5min, 14000 rpm). Endotoxin measurement in the produced vaccine showed ~50 EU/mg. mCuMV_{TT}-RBM vaccine candidate was next characterized using SDS-PAGE, agarose gel, electron microscopy, and dynamic light scattering (DLS). Protein concentration was determined using BCA test.

2.2 | Dynamic light scattering (DLS)

Sample VLP solution (1 mg/ml) was analyzed on a Zetasizer Nano ZS instrument (Malvern Instruments Ltd, UK). The results of three measurements were analyzed by DTS software (Malvern, version 6.32).¹⁶

2.3 | Electron microscopy

Physical stability and integrity of the mosaic CuMV_{TT}-RBM were visualized by transmission electron microscopy (Philips CM12 EM). For imaging, sample grids were glow discharged and 2μl of purified CuMV_{TT}-RBM (3mg/ml) was added for 30s. Grids were washed 3x with ddH₂O and negatively stained with 5 μl of 5% uranyl acetate for 30s. Excess uranyl acetate was removed by pipetting and the grids were air dried for 10min. Images were taken with 84,000X and 110,000X magnification.

2.4 | Binding ELISA assay

To test if the vaccine can bind the relevant human receptor ACE2, the plates were coated with 1μg/ml of ACE2 in PBS at a volume of

50 µl/well. The plate was incubated at 4°C overnight. The plate was washed with PBS, Tween 0.01%. Added 50 µl/well of Superblock solution (Thermo Fisher, 37518) and incubated for 1h at RT on a shaker. The blocking solution was flicked off, and 50 µl of the CuMV_{TT}-RBM or CuMV_{TT}-VLPs at 1 µg/ml was added to the first row of the plate followed by 1:3 dilution. The plate was incubated for 1h at RT, washed with PBS+Tween 0.01%. 50 µl of mouse anti-CuMV_{TT} monoclonal antibody (clone 1-1A8/ batch 2) at a concentration of 1 µg/ml was added to each well as a secondary antibody and incubated for 1h at RT on a shaker. The plate was washed and 50 µl of the detection antibody; HRP labeled goat anti-mouse IgG Fc gamma at a dilution of 1:1000 in PBS-Casein 0.15% was added to each well. The plate was incubated for 1h at RT. The plate was developed, and OD₄₅₀ reading was performed (BioTek, USA).

2.5 | Mice

In vivo experiments were performed using 8- to 12-week-old female, BALB/cOlaHsd wild-type (wt) mice purchased from Harlan (Netherlands). All animal procedures were conducted in accordance with the Swiss Animal Act (455.109.1 – 5 September 2008) of University of Bern. All animals were treated for experimentation according to protocols approved by the Swiss Federal Veterinary Office.

2.6 | Rabbits

A toxicology study was performed in rabbits according to ICH guidelines for the preclinical safety evaluation of vaccines and the preclinical pharmacological and toxicological testing of vaccines. Studies were performed according to the principles of good laboratory practice at the Musculoskeletal Research Unit (MSRU) of the Vetsuisse Faculty of the University of Zürich.

2.7 | Human sera

Human sera were obtained from 5 different COVID-19 convalescent patients which were recruited at the University Hospital of Bern, Bern, Switzerland as described²⁰. Participants were recruited via three different routes: (a) inpatients with a SARS-CoV-2 test result (real-time PCR; RT-PCR), (b) medical personnel of the Inselspital, and

(c) residual material from patients stored at the Liquid Biobank Bern (www.biobankbern.ch). Inclusion criteria of inpatients are as follows: (a) hospitalization in Inselspital, (b) tested positive for SARS-CoV-2 using RT-PCR (nasopharyngeal swab), (c) aged 18 or older, and (d) signed general consent.

2.8 | Vaccination regimen/dose/sera collection

Wild-type BALB/cOlaHsd mice were vaccinated subcutaneously (s.c.) using different regimens and doses as summarized in Table 1. After comparing the efficacy of the different regimens and doses, 100 µg of the vaccine or a control (CuMV_{TT}-VLPs, do not display an epitope) was used in the experiments shown in this study. The regimens used in this study are as follows: D0/D14 (Prime/Boost), D0/D28 (Prime/Boost), and D0/D14/D42 (Prime/1st Boost/2nd Boost). mCuMV_{TT}-RBM candidate vaccine was diluted in 20 mM Tris, 2 mM EDTA in a final volume of 100 µl for final injection. Serum was collected on a weekly basis.

2.9 | Expression and purification of RBD mutants

SARS-CoV-2 RBD_{wildtype}, RBD_{K417N}, RBD_{E484K}, RBD_{N501Y}, RBD_{K417N/E484K/N501Y}, and RBD_{L452R/E484Q} were cloned as a synthetic gene into pTWIST-CMV-BetaGlobin-WPRE-Neo vector (Twist Biosciences, CA, USA) and expressed in HEK293F cells through the Expi293 system (Thermo Fisher Scientific, MA, USA). Purification was performed by IMAC using a HiTrap TALON crude column (Cytiva, Uppsala, Sweden).

2.10 | Enzyme-linked immunosorbant assay (ELISA)

To determine the total IgG antibodies against the candidate vaccine mCuMV_{TT}-RBM in sera of vaccinated mice, ELISA plates were coated with SARS-CoV-2 RBD_{wildtype} or with SARS-CoV-2 Spike (Sinobiological, Beijing, China) at concentrations of either 1 µg/ml overnight. ELISA plates were washed with PBS-0.01% Tween and blocked using 100 µl PBS-Casein 0.15% for 2h in RT. Sera from vaccinated mice serially diluted 1:3 starting with a dilution of 1:20 and incubated for 1h at RT. After washing with PBS-0.01% Tween, goat anti-mouse IgG conjugated to horseradish peroxidase (HRP) (Jackson ImmunoResearch, West Grove, Pennsylvania) was added at 1/2000

Dose	Vaccination Regimen
5 µg prime/5 µg boost	D0/D14
20 µg prime/20 µg boost	D0/D7/D14 D0/D14 D0/D28
100 µg prime/100 µg boost	D0/D14 D0/D28
100 µg prime/100 µg 1 st boost/100 µg 2 nd boost	D0/D28/D42

TABLE 1 Tested doses and vaccination regimens

and incubated for 1h at RT ELISA was developed with tetramethylbenzidine (TMB), stopped by adding equal 1 M H₂SO₄ solution, and read at OD₄₅₀ nm or expressed as Log₁₀ OD₅₀. Detecting RBD-specific IgGs against mutated RBDs was carried out in a similar way.

IgG subclasses were measured from sera collected on day 42 following the same described ELISA protocol. The following secondary antibodies were used: goat anti-mouse IgG1-HRP and goat anti-mouse IgG2a-HRP (1:1000) (Thermo Fischer Scientific, Waltham, Massachusetts), goat anti-mouse IgG2b-HRP (SouthernBiotech, Birmingham, Alabama) 1:4000, rat anti-mouse IgG3-HRP (Becton, Dickinson, Franklin Lakes, New Jersey) 1:2000.

To detect IgA antibodies, the plates were coated with 1μg/ml SARS-CoV-2 RBDwildtype protein and goat anti-mouse IgA POX (ICN 55549, ID 91, 1:1000 dilution) as the secondary antibody was used. An additional step prior to serum incubation was added in order to deplete IgG. 10μl of protein G beads (Invitrogen, USA) were transferred into a tube and placed into a magnet. The liquid was removed and the 75.6μl diluted sera in PBS-Casein 0.15% was added to the beads and mixed. The tube was incubated on a rotator at RT for 10 minutes. The tubes were placed back into the magnet, and ELISA was carried out as described above. Analysis and graphs were created using GraphPad PRISM 9, version 9.1.0 (216), 15 March 2021.

To determine RBD-specific IgG antibodies against the candidate vaccine mCuMV_{TT}-RBM in sera of vaccinated rabbits, ELISA plates were coated with 2μg/ml SARS-CoV-2 RBD_{wildtype} in PBS overnight at +4°C. ELISA plates were washed 4 times with PBST (1x PBS / 0.05% (v/v) Tween 20), and plates were blocked with 200 μL/well Blocking buffer (ThermoFisher, Life Technologies Europe BV, Zug Switzerland). Plates were incubated at +22°C between 2 and 4 h. After removal of the blocking buffer and a washing step, diluted internal standard (1 μg/mL) and the pre-diluted immune sera (1:50) were added to the wells of the first column on the ELISA plate (150 μL/well). The internal standard and the immune sera were then serially threefold diluted in dilution buffer (2% BSA/ PBST). Plates were incubated for 2 h at +22°C and washed. 100 μL/well of detection antibody (1:10'000 diluted in dilution buffer, Peroxidase-conjugated polyclonal goat anti-rabbit IgG (H+L) (Jackson Immuno Research, cat no 111-035-144) was added and incubated for 2h at +22°C. After rigorous washing, 100 μl /well of the OPD detection solution (POD tablets (Sigma cat. no. P6912), phosphate citrate tablets (Sigma cat. no. P4809), 30% H₂O₂ (Sigma cat. No. 1009)) was added and reaction was stopped by addition of 50μL/well 2 M H₂SO₄. Absorption at 490 nm was quantified in each well using the plate reader Spark 10 M (Tecan).

2.11 | Avidity (ELISA)

To test IgG antibody avidity against SARS-CoV-2 full spike protein and RBD protein, threefold serial dilutions of 1/20 diluted mice sera, were added to duplicate ELISA plates coated over night with 1μg/ml RBD or spike protein. After incubation at RT for 1h, the plates were washed once in PBS-0.01% Tween, and then washed 3x with 7 M urea

in PBS-0.05%Tween or with PBS-0.05% Tween for 5min every time. After washing with PBS-0.05%Tween, goat anti-mouse IgG conjugated to horseradish peroxidase (HRP) (Jackson ImmunoResearch, West Grove, Pennsylvania) was added 1/2000 and incubated for 1h at RT. Plates were developed and read at OD₄₅₀.

2.12 | Cytopathic effect-based neutralization assay (CPE)

To determine the neutralizing ability and capacity of vaccine-induced antibodies, a CPE assay was performed using wildtype SARS-CoV-2 (SARS-CoV-2/ABS/NL20). Serum samples were heat-inactivated for 30min at 56°C. Two fold serial dilutions were prepared starting at 1:20 up to 1:160. 100 TCID₅₀ of the virus was added to each well and incubated for 37°C for 1h. The mixture has been added on a monolayer of Vero cells and incubated again for 37°C for 4 days. Four days later, the cells were inspected for cytopathic effect. The titer was expressed as the highest dilution that fully inhibits formation of CPE.

2.13 | Statistical analysis

Data were analyzed and presented as (mean ±SEM) using *Student's t test*, one-way ANOVA or Area Under Curve (AUC) as mentioned in the figure legend, with GraphPad PRISM 9. The value of $p < 0.05$ was considered statistically significant (* $p < 0.01$, ** $p < 0.001$, *** $p < 0.0001$).

2.14 | Continuous flow centrifugation

Bacterial lysates were generated as described in 2.1 and applied to a sucrose gradient in a continuous flow centrifugation (AW Promatix 1000™). The fractions obtained were analyzed by SDS-PAGE, native agarose gel electrophoresis, and electron microscopy.

3 | RESULTS

3.1 | CuMV_{TT}-VLPs constitute an efficient platform for genetically fusing the receptor-binding motif (RBM)

Our first attempt to generate a COVID-19 vaccine using CuMV_{TT} VLPs platform, utilized eukaryotically expressed recombinant RBD which was chemically coupled to the VLPs using Succinimidyl 6-((beta-maleimidopropionamido)hexanoate) SMPH cross-linker²¹. This method resulted in a vaccine candidate that induced high levels of RBD-specific antibodies which were able to strongly inhibit RBD binding to ACE2 and neutralize SARS-CoV-2/ABS/NL20 virus²².

In an attempt to produce a more readily scalable vaccine candidate with better yields, we genetically fused RBM into CuMV_{TT}

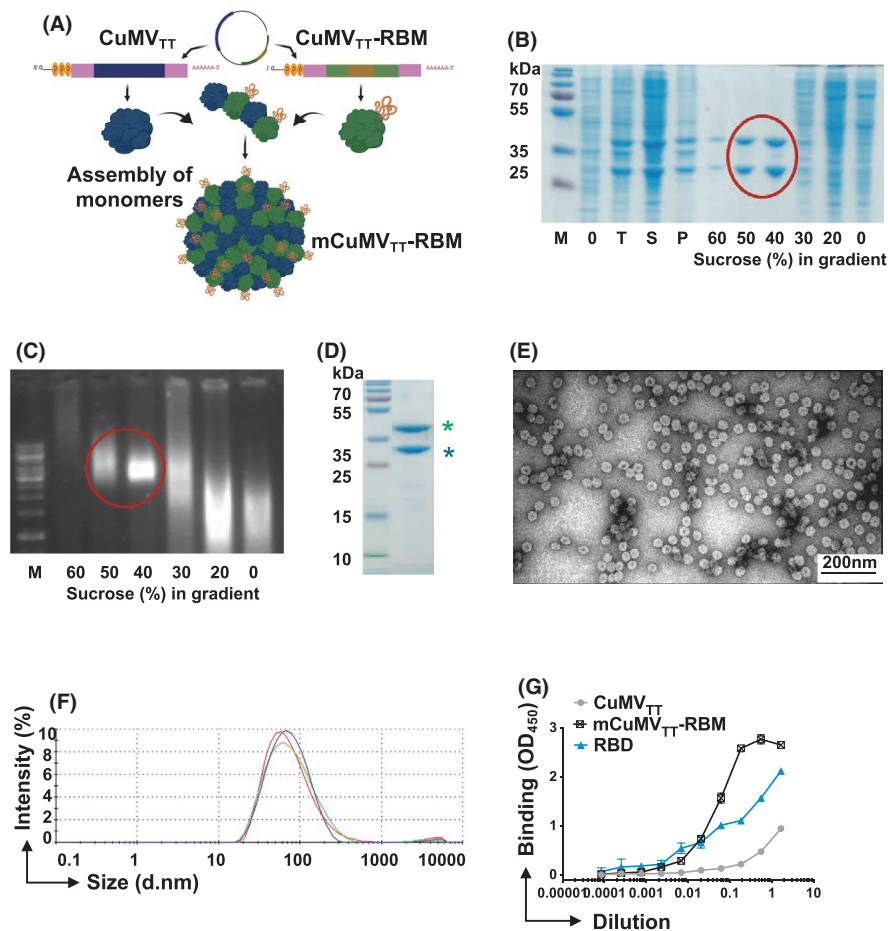

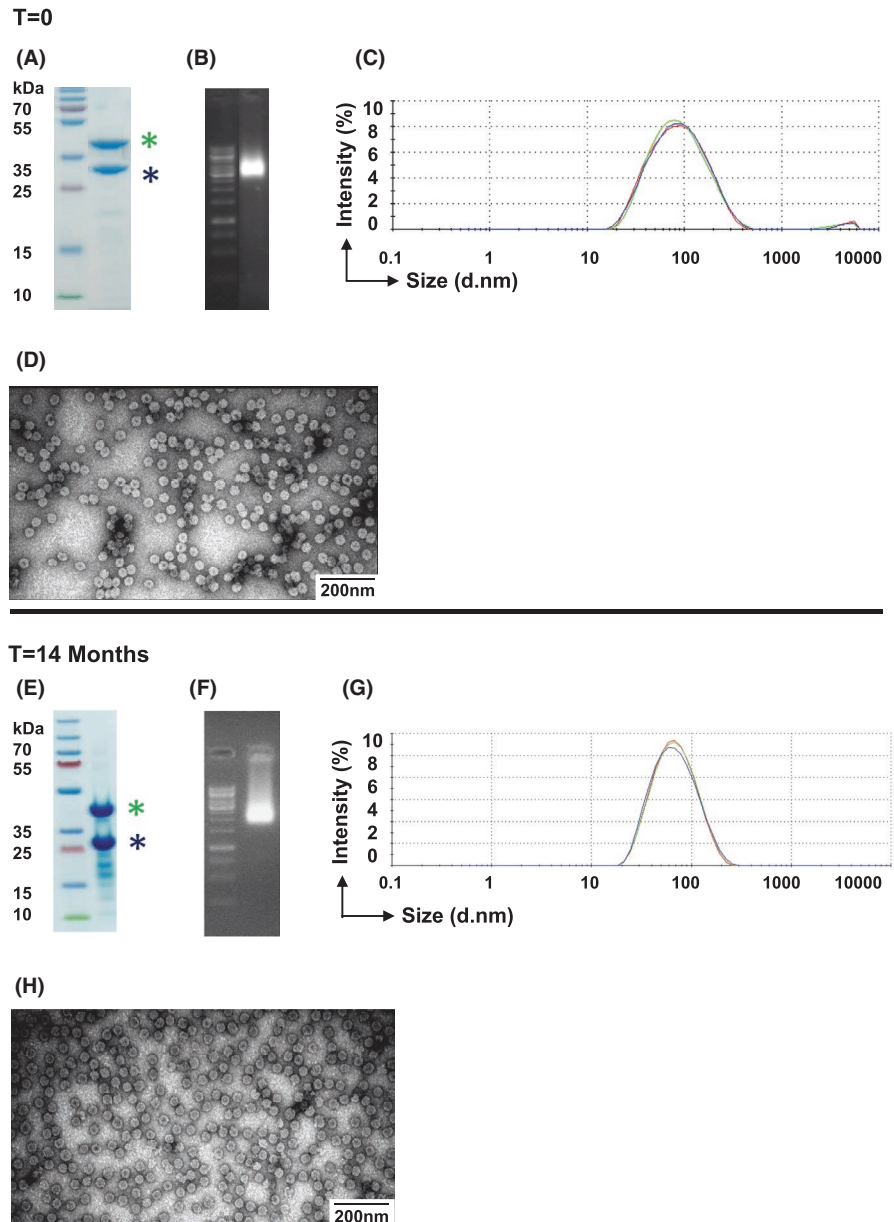

FIGURE 1 CuMV_{TT}-VLPs constitute an efficient platform for genetically fusing the receptor-binding motif (RBM). A, Schematic depiction of *E. coli* cells containing pETDuet-1-derived plasmid, allowing the coexpression of CuMV_{TT}-RBM fusion and unmodified CuMV_{TT} genes and production of mosaic VLPs termed (mCuMV_{TT}-RBM). B, SDS-PAGE analysis of the production and sucrose gradient purification of mCuMV_{TT}-RBM. M—protein size marker (Thermo Scientific), 0—total proteins in *E. coli* C2566 cells before IPTG induction; T—total proteins in *E. coli* C2566 cells after IPTG induction and 18h cultivation at 20°C; S—soluble proteins in *E. coli* C2566 cells after induction and 18 h cultivation; P—insoluble proteins in *E. coli* C2566 cells after induction and cultivation; 60–0—sucrose gradient fractions after separation of cell lysate in Beckman SW32 rotor; mCuMV_{TT}-RBM VLP containing sucrose fractions are labeled with red circle; C, native agarose gel analysis of the sucrose gradient fractions after sucrose gradient purification of mCuMV_{TT}-RBM. M—protein size marker (Thermo Scientific), asterisk (blue) refers to unmodified CuMV_{TT} monomer and asterisk (green) refers to genetically modified CuMV_{TT}-RBM E, Electron microscopy analysis of purified mCuMV_{TT}-RBM VLPs; F, DLS analysis of purified mCuMV_{TT}-RBM VLPs. G, ACE2 binding to mCuMV_{TT}-RBD vaccine candidate, CuMV_{TT}, and RBD alone were used as controls. Plates coated with 1 μg/ml of ACE2. Binding was revealed using anti-CuMV mAb. One representative of 2 similar experiments is shown

to produce a mosaic vaccine as illustrated in Figure 1A. The mosaic vaccine (mCuMV_{TT}-RBM) consists of both unmodified and a genetically modified monomer spontaneously assembling in *E. coli* to form VLPs. The genetically modified monomer displays RBM on the exterior VLP-surface. mCuMV_{TT}-RBM was expressed and produced in *E. coli*. Of note, incorporating either the whole RBD into a mosaic particle or modifying all VLP coat protein subunits with RBM was not successful and resulted in formation of coat protein aggregates and insoluble VLPs (data not shown). Purification of mCuMV_{TT}-RBM was carried out by ultracentrifugation using a 20–60% sucrose gradient (Figure 1B). We have shown previously that using *E. coli* as an expression system facilitates packaging of prokaryotic ssRNA which serves as a TLR7/8 ligand and results in enhanced immune responses

in mice^{17,23} (Figure 1C). The final product mCuMV_{TT}-RBM consists of an unmodified VLP coat protein monomer of ~28 kDa in size while the genetically modified one is ~42 kDa as shown in the SDS-PAGE (Figure 1D). Densitometric analysis suggested 40–50% incorporation of coat protein-RBM fusion molecules into the VLPs. As each VLP contains 180 capsid proteins, 40–50% RBM incorporation means that each VLP has about 70–90 RBM antigens. Electron microscopy confirmed the successful assembly of icosahedral mCuMV_{TT}-RBM into T=3 particles with no sign of aggregation or malformation of particles (Figure 1E). Dynamic light scattering (DLS) revealed a uniform and homogenous peak of hydrodynamic diameter (DH) of ~94 nm (Figure 1F). The observed larger size than seen by electron microscopy is due to water molecules surrounding the VLPs.

FIGURE 2 mCuMV_{TT}-RBM vaccine candidate shows high stability. A and E, SDS-PAGE; B and F, Agarose gel; C and G, DLS analysis of the mCuMV_{TT}-RBM vaccine, D and H, Electron microscopy analysis of mCuMV_{TT}-RBM. Vaccine samples were analyzed directly after production and 14 month following storage at +4°C. Asterisk in (blue), unmodified CuMV_{TT} monomer; asterisk in (green), genetically modified CuMV_{TT}-RBM

To confirm the native conformation of RBM in the context of the mosaic fusion VLP, we tested whether the vaccine candidate was able to bind to ACE2. To this end, the human receptor ACE2 was coated onto an ELISA plate. The candidate vaccine mCuMV_{TT}-RBM or a control CuMV_{TT} VLPs without an RBM insertion were then added followed by anti-CuMV_{TT} secondary antibodies used to detect receptor bound VLPs. The results demonstrated that mCuMV_{TT}-RBM vaccine can bind to ACE2 receptor indicating that RBM exhibits the right native conformation(s) on the surface of the VLPs. The control did not show relevant binding (Figure 1G).

3.2 | mCuMV_{TT}-RBM vaccine candidate shows high stability at +4°C

Next, we tested the stability of mCuMV_{TT}-RBM after storage at +4°C for 14 months. The stability of the vaccine was assessed and compared to a freshly produced vaccine by performing SDS-PAGE

(Figure 2A and E), agarose gel (Figure 2B and F), DLS analysis (Figure 2C and G), and electron microscopy (Figure 2D and H). The results indicated that the vaccine is highly stable for 14 months at +4°C with no signs of degradation.

3.3 | mCuMV_{TT}-RBM induces high levels of specific antibodies with high avidity against RBD and spike protein of SARS-CoV-2

We investigated the immunogenicity of the developed vaccine mCuMV_{TT}-RBM in BALB/c mice using the s.c. vaccination route. We tested different doses and vaccination regimens as summarized in Table 1. The obtained results indicated that administering 100 µg dose elicits the best immune response compared to other tested doses such as 5µg or 20µg (data not shown). Two vaccination regimens (Prime/Boost) have been compared; D0/D14 and D0/D28 as illustrated in Figure 3A. No adjuvants have been added as the vaccine

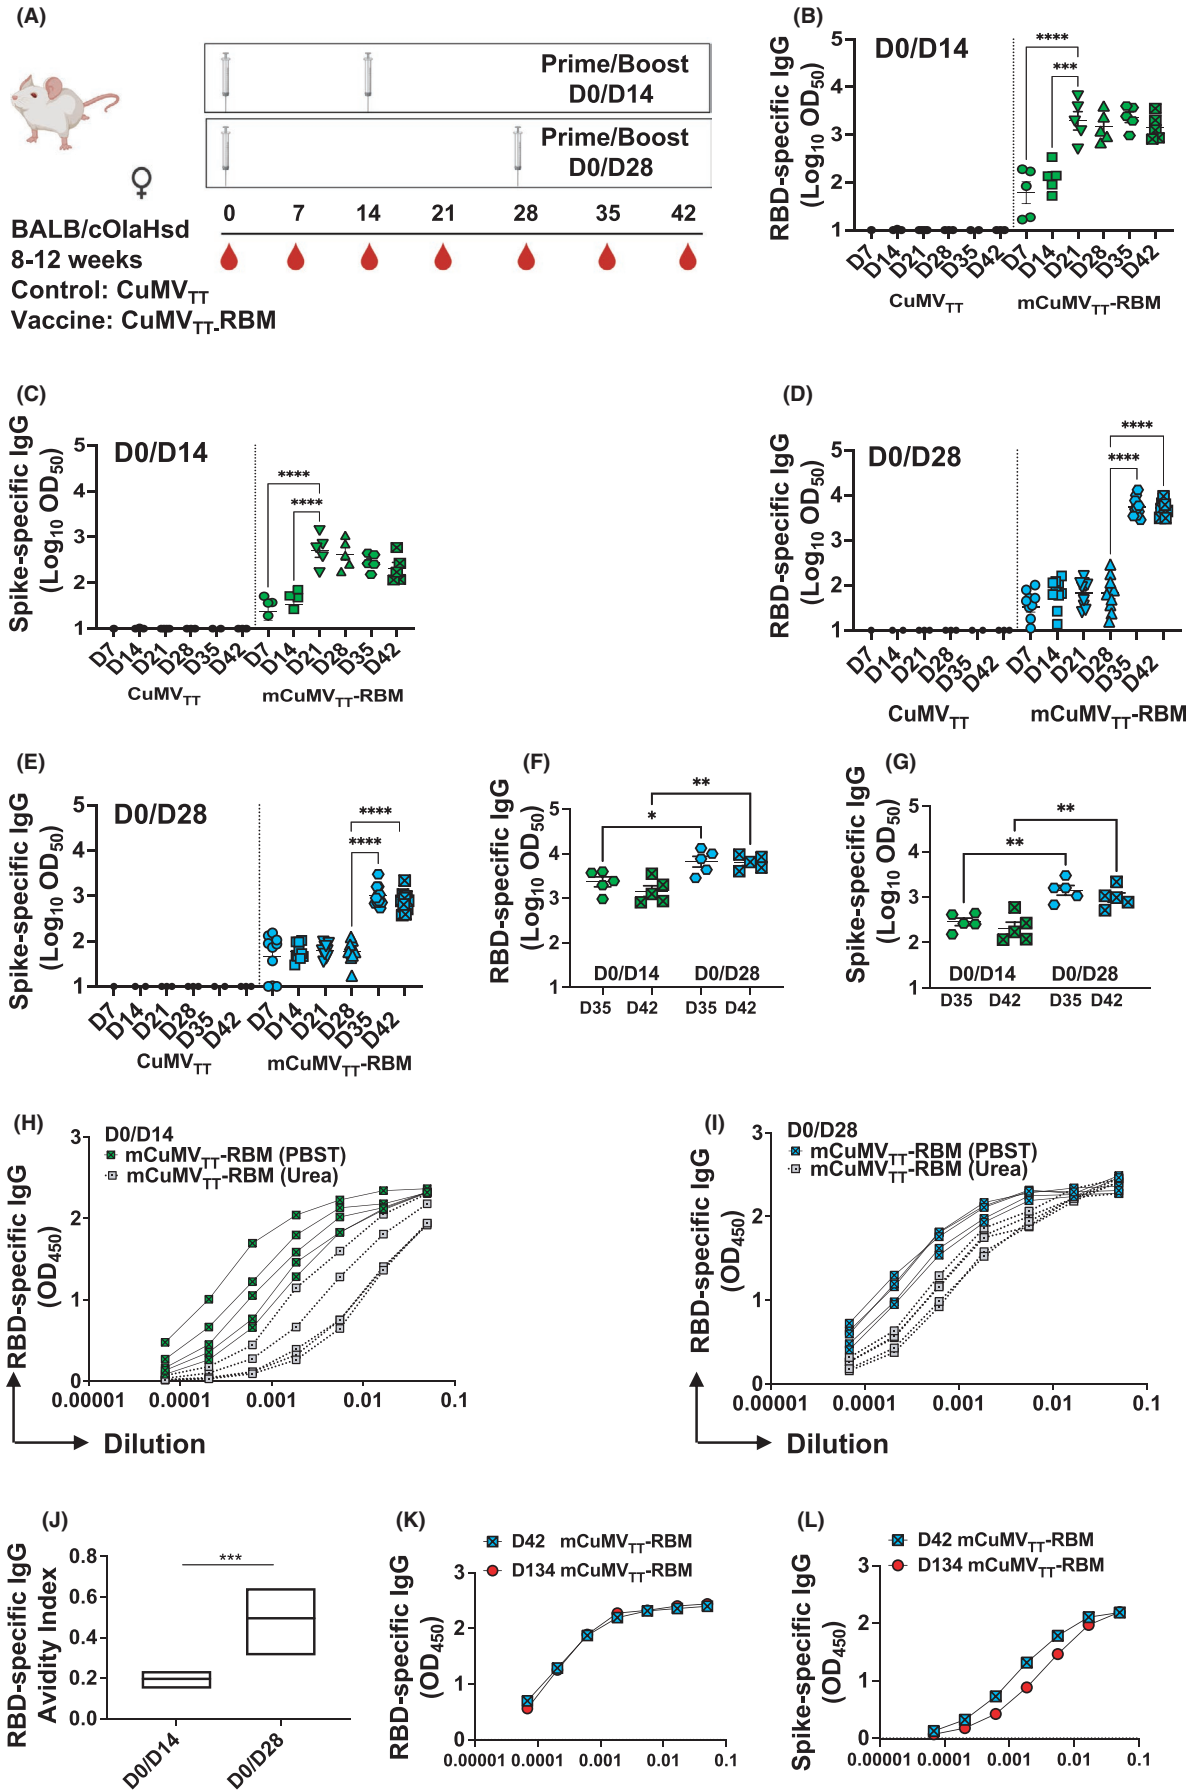

FIGURE 3 mCuMV_{TT}-RBM induces high levels of specific antibodies with high avidity against RBD and spike protein of SARS-CoV-2. H, Avidity of RBD-specific IgG titers in mice vaccinated with mCuMV_{TT}-RBM using D0/D14 regimen, sera were treated with PBST or 7 M Urea. I, Avidity of spike-specific IgG titers in mice vaccinated with mCuMV_{TT}-RBM using D0/D14 regimen, sera were treated with PBST or 7 M Urea. J, Avidity Index of RBD-specific IgG in mice vaccinated with mCuMV_{TT}-RBM using D0/D14 or D0/D28 regimens, sera were treated with PBST or 7 M Urea. K, RBD-specific IgG titer for the group vaccinated with mCuMV_{TT}-RBM on days 42 and 134. L, spike-specific IgG titer for the group vaccinated with mCuMV_{TT}-RBM on days 42 and 134. Statistical analysis (mean ± SEM) using *one-way ANOVA* in B-G or *Student's t test* in J, n=10 or 5. One representative of 3 similar experiments is shown. The value of *p*<0.05 was considered statistically significant (**p*<0.01, ***p*<0.001, ****p*<0.0001)

is self-adjuvanted with the prokaryotic ssRNA packaged during the expression process¹⁵. The collected sera were tested for the induction of antibodies against RBD and spike protein of SARS-CoV-2. The results revealed a successful induction of anti-RBD IgGs as early as seven days following the priming dose using either regimens. The booster dose on day 14 or 28 augmented the response by approximately 10-fold (Figure 3B and D). Antibody responses against the spike protein were also detected following the priming dose albeit to a lower extent, compared to RBD-specific responses. However, the response increased dramatically following the booster dose in both regimens (Figure 3C and E).

When comparing the induced antibody titers following the booster dose for both regimens, D0/D28 regimen showed significantly higher RBD-specific antibodies on days 35 and 42 compared to D0/D14 regimen (*p*. 0.0409 and 0.0033, respectively) (Figure 3F). Such finding was also observed when comparing spike-specific antibodies (*p*. 0.0016 and 0.0021, respectively) (Figure 3G).

To assess the avidity of the induced antibodies, we performed a modified immunoassays using 7 M urea to detach the low avidity antibodies. More specifically, we have compared the avidity of the RBD-specific antibodies in sera collected from day 42 in both regimens (D0/D14) and (D0/D28). The results revealed that ~50% of the induced RBD-specific antibodies are of high avidity when using D0/D28 vaccination regimen versus ~20% only for D0/D14 regimen (*p*. 0.0008) (Figure 3H-J). Similar findings were seen for the induced spike-specific antibodies (*p*. 0.0144) (Figure S1).

It is also of interest to assess the longevity of antibodies induced after vaccination with mCuMV_{TT}-RBM. Accordingly, we have tested RBD- and spike-specific IgG antibodies 134 days following priming. The results revealed that the antibody titers remained stable and remained comparable to the titers seen on day 42 (Figure 3K and L).

mCuMV_{TT}-RBM was also tested in rabbits (males and females) to evaluate the immunogenicity and potential toxicity (tolerability) of the vaccine candidate. Rabbits were vaccinated intramuscularly (i.m.) on day 0 and received booster doses on days 14 and 28. Sera collected on day 42 have shown a strong increase in RBD-specific antibodies (around OD₅₀ of 1:10000) (Figure S2). Toxicological assessments demonstrated no evidence of clinical signs or systemic

toxicity following multiple administrations of mCuMV_{TT}-RBM vaccine candidate. A mild influx of inflammatory cells at the injection site was observed.

3.4 | mCuMV_{TT}-RBM promotes IgA production and IgG responses are dominated by the IgG2a subclass

Previous studies have shown that the different IgG subclasses play an essential role against viruses by complement fixation, enhancing opsonization, and immune effector function²⁴. Accordingly, it is of interest to assess the IgG subclasses induced by the developed vaccine candidate. We therefore tested the vaccine for its ability to induce IgG1, IgG2a, IgG2b, and IgG3. The results indicated that mCuMV_{TT}-RBM induces the production of all four subclasses when binding is assessed on RBD protein as shown in Figure 4A and B. Analysis of Log₁₀OD₅₀ showed a predominance of IgG2a. These results were confirmed when assessing the binding to the spike protein (Figure 4C and D).

Next, we tested the ability of mCuMV_{TT}-RBM to induce immunoglobulin class-switching to IgA using the two regimens D0/D14 and D0/D28. D0/D28 regimen induced higher RBD-specific IgA titers in comparison with D0/D14 regimen (Figure 4E). Determining the Log₁₀OD₅₀ of IgA titers in both regimens confirmed the difference in antibody titers (Figure 4F).

3.5 | Sera of mice vaccinated with mCuMV_{TT}-RBM efficiently recognize SARS-CoV-2 variants of concern (VoC)

We have previously produced a number of RBD variants, including the UK, Brazilian, and Indian VoC^{25,26}, and have shown, as others, that mutations at position E484K strongly reduce recognition by convalescent sera^{26,27}. It is therefore of significant interest that our vaccine induced immune sera recognized all VoC equally well as the wild type (Figure 5A and B). Hence, this vaccine candidate may have the potential to protect equally well against all VoC that have occurred up to now.

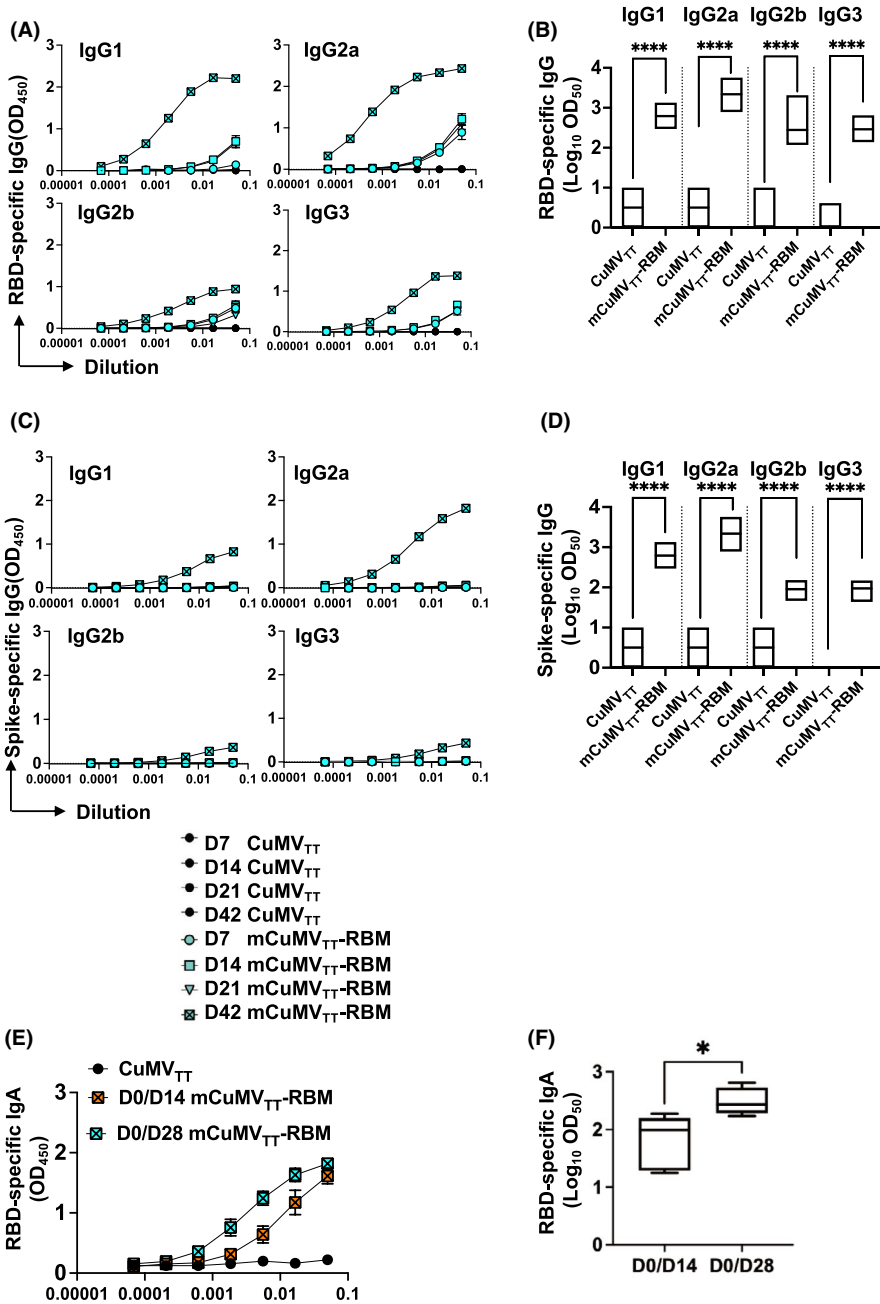

FIGURE 4 mCuMV_{TT}-RBM promotes IgA production and IgG responses are dominated with IgG2a subclass. A, RBD-specific IgG titer for the groups vaccinated with CuMV_{TT} as a control or mCuMV_{TT}-RBM on days 7, 14, 21, and 42 measured by ELISA OD₄₅₀. B, Log₁₀OD₅₀ of RBD-specific IgG titers for the groups vaccinated with CuMV_{TT} or mCuMV_{TT}-RBM on days 7, 14, 21 and 42 (Data from A). C, spike-specific IgG titers for the groups vaccinated with CuMV_{TT} or mCuMV_{TT}-RBM on days 7, 14, 21, and 42 measured by ELISA OD₄₅₀. D, Log₁₀OD₅₀ of spike-specific IgG titers for the groups vaccinated with CuMV_{TT} or mCuMV_{TT}-RBM on days 7, 14, 21, and 42 (Data from C). CuMV_{TT} n=5 and mCuMV_{TT}-RBM n=10. E, RBD-specific IgA titer for the groups vaccinated with CuMV_{TT} or mCuMV_{TT}-RBM using D0/D14 or D0/D28 regimens, measured by ELISA OD₄₅₀. F, Log₁₀OD₅₀ of RBD-specific IgA titer for the groups vaccinated with CuMV_{TT} or mCuMV_{TT}-RBM using D0/D14 or D0/D28 regimens, sera of day 35 was used. CuMV_{TT} n=5 and mCuMV_{TT}-RBM n=5. Statistical analysis (mean ± SEM) using one-way ANOVA in B and D or Student's *t* test in F. One representative of 3 similar experiments is shown. The value of *p* < 0.05 was considered statistically significant (**p* < 0.01, ***p* < 0.001, ****p* < 0.0001).

3.6 | mCuMV_{TT}-RBM induces higher antibody titers in comparison with SARS-CoV-2 convalescent sera

In comparison with infections with other viruses, patients infected with COVID-19 produce neutralizing antibodies at relatively low levels^{28,29}. Hence, we compared the total RBD-specific IgG titers induced in mouse sera after vaccination with mCuMV_{TT}-RBM to SARS-CoV-2 convalescent sera (total of 5 different sera). The results showed that the vaccine induces higher RBD-specific antibody titers even after a single priming dose compared to natural infection with SARS-CoV-2 and the booster injection further increased the RBD-specific antibody responses (Figure S3A and B). Analysis of Area Under Curve (AUC) indicated

a strong difference (*p* < 0.0001) between mouse sera collected on day 14 (after priming) or day 42 (after boost) to convalescent sera (Figure S3C and D).

3.7 | Administration of a second booster dose further enhances antibody response and neutralization capacity of mCuMV_{TT}-RBM

In a next step, we compared the efficacy of vaccinating mice with a total of 2 doses of mCuMV_{TT}-RBM (Prime/Boost) versus 3 doses (Prime/1st Boost/2nd Boost) as illustrated in Figure 6A. The results showed no significant difference in the induced RBD-specific antibody titers following the 1st boost in comparison with sera

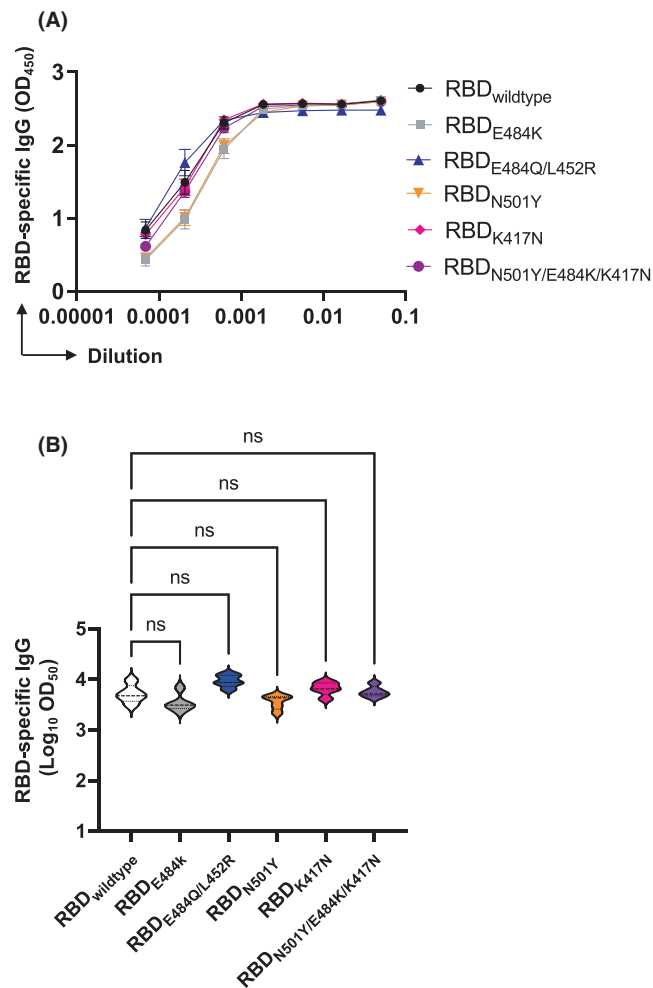

FIGURE 5 Sera of mice vaccinated with mCuMV_{TT}-RBM efficiently recognize SARS-CoV-2 Variants of Concern (VoC). A, RBD-specific IgG titers for the group vaccinated with mCuMV_{TT}-RBM measured by ELISA OD₄₅₀ measured on day 42. B, Log₁₀ OD₅₀ of RBD-specific IgG titers for the group vaccinated with mCuMV_{TT}-RBM (data from A). ELISA plates were coated with either RBD_{wildtype}, RBD_{K417N}, RBD_{E484K}, RBD_{N501Y}, RBD_{K417N/E484K/N501Y}, or RBD_{L452R/E484Q}. Statistical analysis (mean ± SEM) using one-way ANOVA, $n=5$. One representative of 2 similar experiments is shown. The value of $p < 0.05$ was considered statistically significant (* $p < 0.01$, ** $p < 0.001$, *** $p < 0.0001$)

following the 2nd boost (Figure 6B and C). Furthermore, the avidity of the induced antibodies after the 2nd boost shows a slightly higher value when compared to the ones induced following the 1st boost (Figure 6D and E) even though the difference did not reach statistical significance.

To test the capacity of the induced antibodies to neutralize the real virus, we have assessed reduction of cytopathic effect (CPE) using 100 TCID₅₀ of SARS-CoV-2/ABS/NL20. Titers are expressed as the highest dilution that inhibits formation of CPE by 100%. A significant difference in neutralization capacity was seen when comparing sera of day 42 of vaccinated mice vs the control group ($p = 0.0014$). In addition, sera from mice after the 2nd boost (day 63) further enhanced the neutralization titer when compared to

the control group ($p < 0.00001$) or the group received only 1 boost ($p = 0.0021$) (Figure 6F). The obtained results showed the capacity of the vaccine candidate to completely block the cytopathic effect of the virus.

3.8 | Efficient upscaling of mCuMV_{TT}-VLPs vaccine candidate

Manufacturability, in particular scalability and production yields are a critical attribute in selecting vaccines candidates to address a global pandemic. For this reason, we focused here on a VLP-based vaccine that can be efficiently produced in bacteria. Indeed, as the RBM of SARS-CoV-2 is not glycosylated and has no other post-translational modifications, it may be an optimal candidate for a VLP-based vaccine candidate produced in *E. coli*.

Continuous flow ultracentrifugation is a method used to produce >80% of the annual global influenza vaccine inventory which is approximately 1.5 billion doses³⁰; continuous flow ultracentrifugation is thus an ideal and an established method for purification at large scale. To assess the potential yields of our production process, we produced a batch of mCuMV_{TT}-RBM in a 2-litre fermenter and purified the resultant VLPs by continuous flow ultracentrifugation (Figure S4). SDS-PAGE analysis showed good incorporation of RBM and EM-analysis showed well-formed particles (Figure S4B-D). The process yield from 2-litre fermentation volume was approximately 0.5 g. This would correspond to 2.5 mio doses produced in a single 1000-litre fermentation run. As this process is not optimized, there is the potential to significantly improve the already impressive yields.

4 | DISCUSSION

In the current study, we investigated a novel VLP-based vaccine for COVID-19. Specifically, we have generated a mosaic VLP-vaccine using the plant-derived cucumber mosaic VLPs (CuMV_{TT}). Mosaic VLPs are well known in the field with GSKs RTS, S malaria vaccines as the most prominent member in the field^{31,32}. The mosaic vaccine candidate consists of an unmodified monomer and a genetically modified monomer that incorporates the RBM of SARS-CoV-2. The RBM was chosen as the target epitope due to the fact that RBD/RBM are considered the immunological Achilles' heel of SARS-CoV-2 and unlike RBD, RBM does not show any glycosylation, likely facilitating protein-protein interactions with ACE2^{11,33,34}. Furthermore, incorporating the whole RBD into CuMV_{TT} did not allow the formation of VLPs most likely due to steric constraints. The used genetic fusion technique in this study facilitated the assembly of $T=3$ icosahedral mosaic VLPs which is essential for effective induction of a humoral immune response¹⁴. Using this technique, we have recently developed a vaccine against MERS-CoV by incorporating the RBM of MERS-CoV into CuMV_{TT}. The developed vaccine-induced antibodies that completely neutralized MERS-CoV/EMC/2012 isolate⁴⁶.

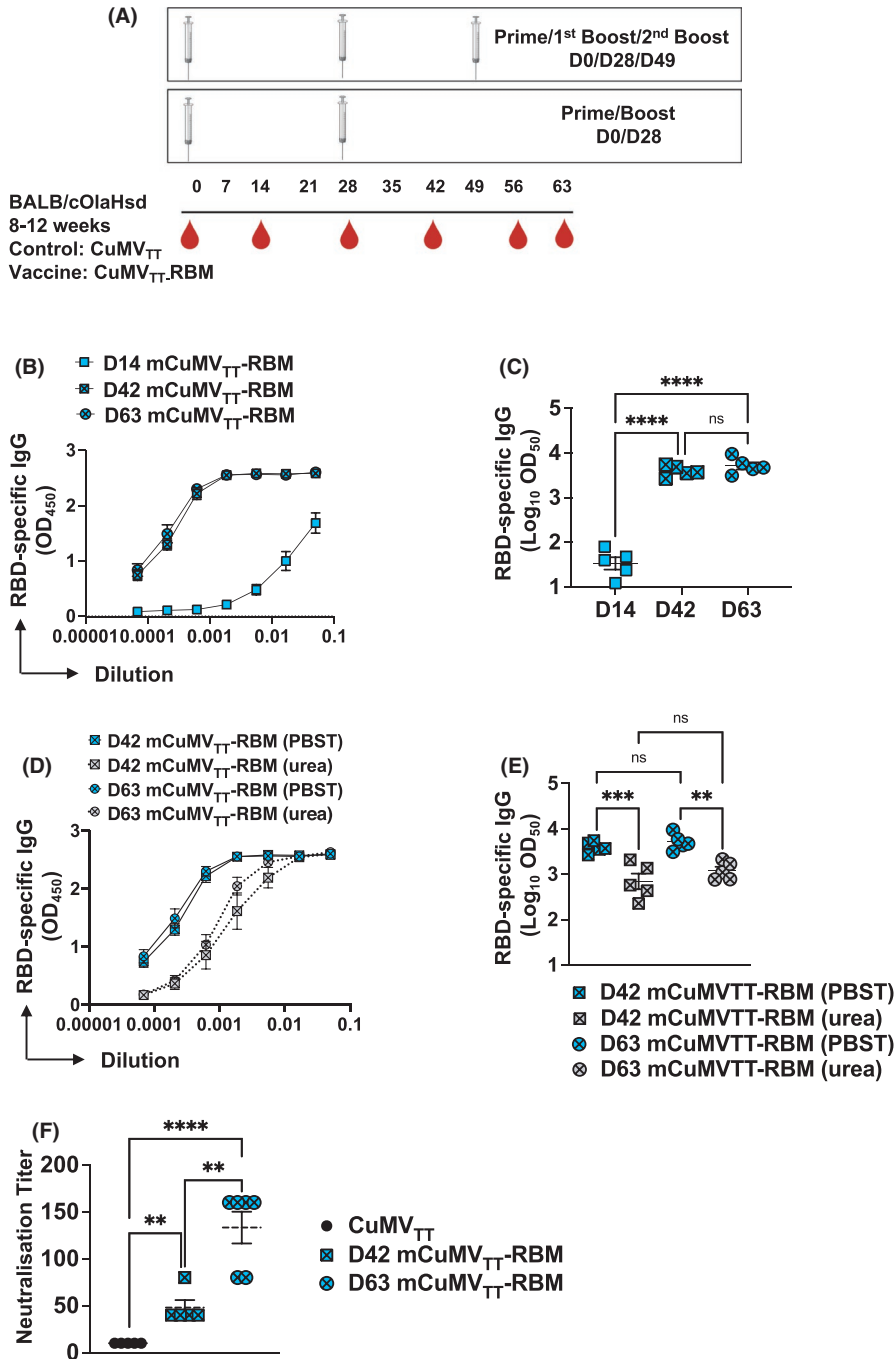

FIGURE 6 Administration of a second booster dose further enhances antibody response and neutralization capacity of mCuMV_{TT}-RBM. A, Vaccination regimen D0/D28 or D0/D28/D49, bleeding schedule, and groups. B, RBD-specific IgG titers for the groups vaccinated with mCuMV_{TT}-RBM on day 14 (after prime), day 42 (after 1st boost), and day 63 (after 2nd boost) measured by ELISA OD₄₅₀. C, Log₁₀ OD₅₀ of RBD-specific IgG titers for the groups vaccinated with mCuMV_{TT}-RBM on day 14 (after prime), day 42 (after 1st boost), and day 63 (after 2nd boost) (Data from B). D, Avidity of RBD-specific IgG titers in mice vaccinated with mCuMV_{TT}-RBM on day 42 (after 1st boost) and day 63 (after 2nd boost) measured by ELISA OD₄₅₀, sera were treated with PBST or 7 M Urea. E, Log₁₀ OD₅₀ of RBD-specific IgG titers in mice vaccinated with mCuMV_{TT}-RBM on day 42 (after 1st boost) and day 63 (after 2nd boost) (data from D). F, Neutralization titer (CPE) for sera from mice vaccinated with CuMV_{TT} as a control group, mice vaccinated with mCuMV_{TT}-RBM, sera from day 42 (after 1st boost), and sera from day 63 (after 2nd boost). Statistical analysis (mean ± SEM) using Student's *t* test, *n*=5. One representative of 2 similar experiments is shown. The value of *p*<0.05 was considered statistically significant (**p*<0.01, ***p*<0.001, ****p*<0.0001)

Furthermore, we have shown that fusing RBM into AP205-VLPs results in an effective vaccine candidate which induced RBD- and spike-specific antibodies which were capable of neutralizing the wild-type virus SARS-CoV-2/ABS/NL20³⁵. Development of AP205-RBM vaccine required a refolding process which typically results in lower amounts of correctly folded target protein and may be distinguished from re-assembly processes used for HPV and hepatitis E virus (HEV) vaccines³⁶. The simplicity of the downstream processing at industrial scale is therefore a major advantage of the current vaccine candidate.

Using CuMV_{TT}-VLPs as a vaccine platform, we were able to generate soluble mosaic VLPs. Densitometric analysis indicated 40–50%

incorporation of RBM containing VLP subunits. Using Sandwich ELISAs, we have shown that mCuMV_{TT}-RBM vaccine candidate is able to detect and bind to the viral receptor ACE2. This confirms that the RBM displayed and fused to the VLP, has the correct conformation which is essential for the induction of the appropriate neutralizing antibody response. Expression in *E. coli* facilitates the packaging of bacterial RNA which serves as TLR7/8 ligand. We have shown previously that VLP-based vaccines are capable of inducing IL-21 independent secondary plasma cells only in the presence of TLR7/8 agonist such as bacterial ssRNA^{17,23}. Additionally, TLR7/8 agonist polarizes the immune response toward T_H1 and cytotoxic T cells which is essential to avoid enhanced disease as shown in preclinical

challenge models¹⁰. A recent study has shown that IgA antibodies in serum, saliva as well as bronchoalveolar lavage dominated the early response against SARS-CoV-2 infection in comparison with IgG and IgM. In addition, IgA serum antibodies were more potent at neutralizing wild-type SARS-CoV-2 than IgG³⁷. We have previously shown that RNA-loaded VLPs may induce IgA responses, again in a TLR7/8 dependent manner^{17,38}. This appears particularly important for SARS-CoV-2 and other respiratory disease-causing viruses, such as SARS-CoV and MERS-CoV-2, as IgA may be able to neutralize the virus locally in the lung without causing inflammation, a feature that may be particularly critical in patients with high viral load³⁹. Thus, it is therefore of key importance that our newly developed vaccine candidate is able to induce a significant increase in serum IgA levels. Whether the increased serum IgA levels in mice can translate to correspondingly high IgA levels in humans, in particular at mucosal sites, needs to be established.

We have also shown that mCuMV_{TT}-RBM vaccine candidate induces high IgG responses in mice and rabbits. The response was further augmented following one booster dose. The avidity of an antibody is defined as the binding strength through points of interaction with the cognate antigen. It can be quantified as the ratio of the dissociation constant K_d for the intrinsic affinity over the one for the functional affinity of an antibody⁴⁰. Avidity and functional affinity terms can be exchanged in a looser sense⁴¹. Using an avidity ELISA, we observed that a D0/D28 vaccination regimen induced better quality of anti-RBD and spike antibodies in comparison with D0/D14 regimen. Furthermore, the addition of a 2nd booster dose showed a slight increase in the avidity of the induced RBD-specific IgG avidity but was not statistically significant. This may indicate that it takes longer to induce such high-affinity/avidity antibodies at least in the case of mCuMV_{TT}-RBM.

An ideal vaccine would have a long shelf life at ambient temperatures, nevertheless, many commercial vaccines require storage temperatures between +2–4°C⁴². While maintaining a vaccine in a cold chain below freezing temperature can be difficult in developed countries, it is particularly challenging and sometimes prohibitive for developing countries⁴³. It is therefore an important feature of our vaccine candidate to show high stability for long periods at +4°C.

Some studies have shown that neutralizing antibodies against SARS-CoV-2 are low in general and wane relatively rapidly⁴⁴; some patients may even completely lack long-lasting SARS-CoV-2 antibodies^{28,29}. This may be explained by coronaviruses morphological structure as they are large particles with long spike proteins resulting in RBD trimers spaced by 25 nm. Other viruses and VLPs are capable of inducing optimal and long-lived neutralizing antibodies thanks to the 180 monomers forming a repetitive surface structure with epitopes spaced by 5–10 nm²⁸. The induced antibodies using mCuMV_{TT}-RBM vaccine could be detected at similar levels 3 months following the booster immunization, indicating longevity of the induced response.

The most important goal of any anti-viral vaccine is the induction of neutralizing antibodies that can inhibit SARS-CoV-2 infection. Our

test sera were probed for their ability to inhibit a cytopathic effect of wildtype SARS-CoV-2 isolate on Vero cells. The induced antibodies have shown good neutralizing capability of the virus in particular following the 2nd booster dose.

We have not directly measured the induction of T_H cell responses by our vaccine candidate, mostly because the expected effector mechanism is induction of neutralizing antibodies. In addition, the size of the RBM may be too small to reliably induce a T_H cell response in inbred mice. However, we have previously shown that VLP-specific T_H cell responses mediate isotype-switch for B cells specific for antigens displayed on the VLPs. Furthermore, the bacterial RNA packaged in VLPs, such as CuMV_{TT}, drive CD8, and T_H1 responses^{47,48}.

We and others have shown recently that N501Y mutation enhanced the binding affinity to ACE2 but did not significantly affect the recognition of RBD by convalescent sera. On the other hand, E484K mutation resulted in abolished recognition by convalescent sera⁴⁵. mCuMV_{TT}-RBM is shown here to induce antibodies of much higher affinity/avidity than SARS-CoV-2 typically does in humans. This increased affinity/avidity translates to increased cross-reactivity with SARS-CoV-2 VOC. Indeed, antibodies induced by the here presented vaccine candidate recognizes VoCs from Brazil, UK, and India with equal efficiency suggesting that our vaccine can protect against the new variants.

In addition to stability and high immunogenicity, production yields of mCuMV_{TT}-RBM are of key importance. Indeed, we were able to show in 2-litre bioreactor and continuous flow centrifugation that millions of doses may be produced in a single 1000-litre fermenter run. This is particularly important for less affluent countries, where affordability of vaccines is an important aspect.

Collectively, we have shown in this study that our novel mosaic VLP-based vaccine candidate can efficiently induce high levels of specific anti-RBD and spike antibodies that effectively neutralize SARS-CoV-2 and highly cross-recognize all emerging viral VoC tested. As COVID-19 continues to represent a global threat to human health, it seems rational to further develop this vaccine candidate.

ACKNOWLEDGMENT

This work was supported by Saiba AG and Inselspital Bern. We thank PD Dr. Alexander Eggel and Dr. Daniel Brigger for providing wildtype RBD protein.

CONFLICT OF INTEREST

M. F. Bachmann is a board member of Saiba AG and holds the patent of CuMV_{TT}-VLPs. G. T. Jennings and S. A. Walton work for Saiba AG. M. Mohsen and J. Sobczak received payments by Saiba AG to work on the development of a vaccine against Dengue Fever in the framework of a Eurostars grant. M. F. Bachmann, T. M. Kündig and M. O. Mohsen are shareholder of Saiba AG.
