# ILLINOIS HYBRID CORN TESTS 1944

By G. H. DUNGAN, J. H. BIGGER, A. L. LANG,  
BENJAMIN KOEHLER, and OREN BOLIN<sup>1</sup>

**N**INETY-SIX PERCENT of the corn acreage in Illinois in 1944 was planted with hybrid seed. The average yield for the state was estimated to be 45 bushels an acre despite the fact that yields in some areas were seriously cut by too little rainfall.<sup>2</sup> Such a state average under the growing conditions of 1944 is evidence of the adaptability and drouth-resistance of hybrid corn.

## PLAN OF THE TESTS

**Number of hybrids and their source.** Two hundred thirty-seven hybrids were grown on seven Illinois test fields in 1944. Thirty-four companies and individuals, including the Kansas as well as the Illinois Agricultural Experiment Station, furnished the seed for the tests.

Seventy-two hybrids were tested at the Mt. Morris, Galesburg, and Milford fields; 60 at Sullivan and Alhambra; 60 on the bottomland field at the Dixon Springs Experiment Station, and 14 on the upland field.

Most of the seed for planting the test fields was taken directly from the warehouses of the producers entering the corn. In a few instances producers delivered small quantities to the Experiment Station. Seed of Illinois and United States hybrids in commercial production was obtained from the Illinois Crop Improvement Association. Seed of Kansas hybrids and Illinois hybrids not in commercial production was supplied by the respective Experiment Stations.

Most of the hybrids selected for testing are extensively grown. Some experimental hybrids were included because they had shown promise for commercial production in preliminary tests. A few hybrids were put in the tests mainly to meet the field-performance requirement for certification.

<sup>1</sup>G. H. DUNGAN, Chief in Crop Production, A. L. LANG, Associate Chief in Soil Experiment Fields, BENJAMIN KOEHLER, Chief in Crop Pathology, OREN BOLIN, Assistant Chief in Plant Genetics, Illinois Agricultural Experiment Station; J. H. BIGGER, Associate Entomologist, Illinois State Natural History Survey.

<sup>2</sup>Estimates for the acreage of hybrid corn and the average yield for the state were furnished by the ILLINOIS COOPERATIVE CROP REPORTING SERVICE, Illinois State Department of Agriculture cooperating with the U. S. Department of Agriculture.

Table 1.—GENERAL INFORMATION: Illinois Cooperative Hybrid Corn Tests, 1944

Field	County and location in state	Number of entries	Date planted	Date harvested	Average acre-yield		Average moisture in grain	Average erect plants
					Total	Sound

	Upland.....	14	June 1	Nov. 1	22.0	21.0	18.3	99.6

COOPERATORS: EARL KUMP, *Ogle county*; EARL and WEBSTER GEHRING, *Knox county*; CROW'S HYBRID CORN COMPANY, *Iroquois county*; R. B. VANDEVEER, Farm Manager, Illinois Masonic Home Farm, *Moultrie county*. The Alhambra field in Madison county is conducted by the Illinois Station. The Pope county field at Robbs is part of the Dixon Springs Experiment Station.

**Soil characteristics of fields.** The test fields were medium to high in productivity, and each represents a soil type common to the region where it is located. Care was taken to have each field as uniform as possible in soil type, productivity, and drainage. The field on the bottomland at the Dixon Springs Experiment Station at Robbs was the most variable in productivity, and the Alhambra field contained a number of "slick spots."

Tests were conducted on the same farms as in 1943, but in different fields on these farms. The approximate location of the test fields is shown on the map on the front cover. General information on soil characteristics and soil management is given in Table 2.

**Method of planting.** All test plots were planted by hand on land prepared in the regular way for corn. Each plot consisted of 2 rows 10 hills long, except on the bottomland field at Dixon Springs, where the plots were all 2 rows wide and 8 hills long. Three kernels were dropped in each hill except on both fields at Dixon Springs where only 2 kernels were planted. Six plots of each entry arranged in controlled random order were planted on all fields, and data from all plots were included in the results. The only correction for imperfect stand was an adjustment for missing hills.

## WEATHER CONDITIONS

Wet weather delayed corn planting beyond the usual date in most sections of the state and especially in the extreme southern and eastern areas. Good stands were obtained on all the test fields.

Deficiency of moisture during July and August was a severe handi-

Table 2.—TESTING FIELDS: Soil Characteristics and Management Practices

Soil type	Lime requirement	Available phosphorus	Available potassium	Previous crops and soil management
Northern: Mt. Morris				
Tama silt loam . . . . .	<sup>tons</sup> 3	Low	Low	Small grain 1942; clover hay and pasture 1943; moderate application of manure for corn.
West north-central: Galesburg				
Muscatine silt loam . . . . .	3	Medium	Medium	Corn 1936, 1937; oats 1938; clover 1939; corn 1940, 1941; oats-rape hog pasture 1942; clover 1943. Rock phosphate applied 1924; limestone applied 1941; manure applied ahead of first-year corn.
East north-central: Milford				
Milford clay loam . . . . .	0	High	Medium	Alfalfa meadow 1942, 1943; rock phosphate applied for alfalfa.
South-central: Sullivan				
Flanagan silt loam . . . . .	2	High	Medium	Oats 1940; alfalfa 1940-1943 (fall-plowed); corn 1944.
Southern: Alhambra				
Putnam silt loam . . . . .	None	High	Low	Oats (sweet clover) 1941; soybeans 1942; wheat (sweet clover 1943).
Extreme southern: Robbs (Dixon Springs)				
Upland field: Ava silt loam . .	None	Low	Low	Soybeans 1941; winter grain 1942; sweet and red clover 1943. Limestone and phosphate applied 1940.
Bottomland field: Bonnie silt loam . . . . .	2	Low	Low	Corn harvested for silage 1943, winter rye pasture plowed down for corn, no soil treatment.

R. S. SMITH, Chief in Soil Physics and Soil Survey, has approved the soil type designation, uniformity, and physical characteristics of the above fields.

cap to the crop in all sections of the state except the northern. It was most critical in the southern areas. The low average yields at Alhambra and on the Dixon Springs field at Robbs, as shown in Table 1, reflect the effect of the moisture shortage. Corn on the upland field at the Dixon Springs Experiment Station was almost a failure.

## INSECT PESTS

**Chinch bugs.** The insect that caused the greatest damage to corn in Illinois in 1944—about 5 million dollars' worth—was the chinch bug, *Blissus leucopterus* (Say).

In the test field at Alhambra the damage was somewhat obscured by drouth damage. In late summer, however, it was possible to get

some measure of the destruction caused by this insect and correlate it later with the test weights of the grain. The hybrids with the highest test weights (*Table 15, page 473*) had been least hurt by chinch bugs. Some idea of the relative ability of the different hybrids to withstand chinch bug attack may be obtained by studying these test weights.

**Southern corn rootworm.** A great deal of lodging in cornfields in the northern half of the state was caused by the southern corn rootworm, *Diabrotica duodecimpunctata* (F.), in 1944; but Sullivan, in Moultrie county, was the only test field attacked. Altho the lodging on this field was not as severe as it was in many farmers' fields, it was heavy enough so that satisfactory records of damage could be taken at harvest time. As shown in *Table 13, page 471*, 4.3 to 45.7 percent of the plants lodged 30 degrees or more. Comparatively few hybrids, however, developed the more severe lodging.<sup>1</sup>

**European corn borer.** A moderate increase in the abundance of the European corn borer, *Pyrausta nubilalis* (Hbn.), took place in 1944. The increase was most marked in the northern part of the state north of a line drawn from about the middle of Vermilion county to Mercer county. This line is of course only approximate but it is as accurate as can be estimated at this time.

Appreciable amounts of breakage due to borer attack were found in the test fields at Milford in Iroquois county and at Mt. Morris in Ogle county (*Table 6, page 464*). Records were made of all plants broken over below the ear at harvest time when the break was at the point of visible borer attack.

None of the hybrids in these tests showed outstanding resistance to the corn borer. At Milford 4.7 to 19.3 percent of the plants were broken below the ear. The average for the field was 10.2 percent. Since a difference of 5.5 between percentages is necessary for the difference to mean anything, one has to go to the 41st entry, for example, before finding one that is significantly less good in this respect than the first.

Borer breakage at the Mt. Morris field was considerably less than at Milford, ranging from 1.3 to 9.5 percent and averaging 4.6 percent. On this field a difference of 4.1 between percentages is necessary for significance. This means that one has to go down to the 48th entry in *Table 6* before finding one that can be said to be less good in this respect than the first entry.

With heavier infestations, which may develop, differences between hybrids may become more apparent.

**Corn earworm.** Injury from the corn earworm, *Heliothis armigera* (Hbn.), occurred at Dixon Springs, in Pope county, on both

<sup>1</sup>The method of taking records and computing the resistance ratings are standard and are described in Bulletin 500 of this Station, which reports the 1943 hybrid corn tests.

the upland and the bottomland fields. Every ear except those on the long-husked hybrids was fed upon by earworms, and *Fusarium* rot was prominent on the injured kernels. Practically all the rot damage to the corn on the Dixon Springs test fields was caused by fungi that entered the kernels thru wounds inflicted by earworms.

**Grasshoppers.** Damage by grasshoppers (*Locustidae*) was moderate at Alhambra. It was not heavy enough to bring out differences between the hybrids.

## DISEASE DAMAGE<sup>1</sup>

No very serious damage to corn from disease occurred in any large area of Illinois in 1944. Moderate losses from various diseases nevertheless added up to a sizable damage in total.

**Seedling diseases.** Benefits obtained from seed treatments are believed to be due entirely to the effectiveness of such treatments in reducing damage from seedling diseases. Damage from the numerous organisms that cause these diseases is greatest when the seed germinates in cold, wet soil, especially in cold soil.

In tests on the University south farm at Urbana in 1944, significant increases in yield were obtained by treating the seed. The seed was

<sup>1</sup>Estimates of losses are based, for the most part, on comparison of separate observations made by G. H. BOEWE, Illinois State Natural History Survey; J. S. TIDD, Federal Emergency Plant Disease Survey, and BENJAMIN KOEHLER, Department of Agronomy, University of Illinois.

Table 3.—RESPONSE TO SEED TREATMENT: Arasan Applied at Rate of One Ounce per Bushel of Seed, Urbana, 1944

<sup>a</sup>For pedigrees see Table 4. There were eight replicated plots of each hybrid.

planted on May 13, which is within the generally recommended planting time, and Arasan was used at the rate of 1 ounce per bushel of seed.

In this test (*Table 3*) increases ranged from 1.3 to 4.7 bushels following seed treatment, and all but three of the increases were significant. The average increase was 3.2 bushels an acre.

Different hybrids responded somewhat differently to seed treatment. In previous tests, however, seed of the same hybrid from different sources also responded differently. This is to be expected since the conditions under which seed is produced influences the extent of seed infection, seed-coat injuries, and the physical and chemical nature of the seed.

**Root rots.** Loss from root rot on field corn in Illinois was estimated as 2 percent in 1944. This was somewhat less than in 1943.

**Diplodia stalk rot.** Premature dying of scattered plants occurred in many fields in south-central Illinois by September 1, and in many areas farther north at a little later date. Examination of fields in 36 representative counties in October showed about 45 percent of the plants infected with *Diplodia* stalk rot. Loss in yield was estimated at 3.5 percent.

**Stewart's disease.** This disease was moderately prevalent in the leaves of dent corn thruout most of south-central Illinois, but for the most part damage was light.

**Helminthosporium leaf blight.** This disease was practically absent in 1944, tho it had attracted considerable attention in 1942. Dry conditions during the summer appear to keep it in check.

**Smut.** Loss from smut was less than normal—about .7 percent.

**Ear rots.** All types of ear rot together damaged about 5.1 percent of the kernels in the 1944 corn crop. *Diplodia* damaged about 3 percent, twice as much as in 1943. Damage from *Fusarium moniliforme* was about 1.3 percent, the same as in 1943. Other types averaged about .8 percent.

In a test at Urbana (*Table 4*) various hybrids showed highly significant differences in rot damage. Differences in physiological or chemical nature of the kernels, in husk coverage, and in angle at which the ear is borne—whether it points upward or is declined downward—are known to cause differences in a hybrid's reaction to ear-rot infection. Illinois 2059(W), which in *Table 4* ranks first in freedom from rot damage, also ranked first in good husk coverage, and 60 percent of the ears were declined downward on October 5. This hybrid also ranked first in yield (*Table 3*).

Hybrids may rank differently in different seasons in their susceptibility to ear rot because the different kinds of rots vary in importance from year to year, and also because hybrids respond differently to different seasonal conditions. In this test, for example, Illinois 784 ranked significantly below Illinois 201, whereas in some previous tests it ranked higher.

Table 4.—DAMAGE FROM KERNEL ROT: Figures Are Based on Examination of Shelled Corn, Urbana, 1944

Rank	Entry <sup>a</sup>	Pedigree of entry	Rot damage <i>per cent.</i>
1	Illinois Hybrid 2059(W)	(Ky27 × Cl. 61) (33-16 × K6)	3.37
2	Illinois Hybrid 960	(R4 × Hy) (701 × L317)	3.39
3	U. S. Hybrid 35	(WF9 × 38-11) (R4 × Hy)	3.72
4	Illinois Hybrid 101	(WF9 × M14) (CC7 × 187-2)	4.11
5	Illinois Hybrid 273-1	(WF9 × 38-11) (187-2 × O7)	4.35
6	Illinois Hybrid 751	(A × 90) (WF9 × Hy)	4.72
7	Illinois Hybrid 200	(WF9 × 38-11) (K4 × L317)	4.81
8	Illinois Hybrid 201	(WF9 × 38-11) (187-2 × L317)	5.07
9	Illinois Hybrid 21	(WF9 × 38-11) (Hy × 187-2)	5.14
10	Illinois Hybrid 972-A1	(WF9 × O7) (Hy × L317)	5.32
11	Illinois Hybrid 1182-1	(WF9 × 38-11) (187-2 × RR98)	5.35
12	Illinois Hybrid 246	(WF9 × Hy) (187-2 × L317)	5.42
13	Illinois Hybrid 1173	(WF9 × Hy) (RR98 × 187-2)	6.07
14	Illinois Hybrid 804	(5120 × 38-11) (K4 × L317)	6.19
15	Illinois Hybrid 448	(38-11 × Kys) (K4 × L317)	6.30
16	Illinois Hybrid 206	(WF9 × 38-11) (5120 × L317)	6.51
17	U. S. Hybrid 13	(Hy × L317) (WF9 × 38-11)	6.56
18	Illinois Hybrid 784	(Hy × 5120) (K4 × L317)	7.72
	Difference needed for significance		1.68

<sup>a</sup>There were eight 40-hill plots of each hybrid. All the ears of each plot were shelled and a representative sample taken with a special sampling device.

This is the first time the relative susceptibility of some of these hybrids to rot damage has been accurately measured. It had been previously established, however, in a four-year test that Illinois 960 was significantly less susceptible to rot than Illinois 201, Illinois 784, and U.S. 13.

## MEASURING PERFORMANCE

The entries in the 1944 test are listed in the tables in the order of their total yields. Two or more entries having the same total yield are given the same rating, but the one having the higher yield of sound corn is placed first. Those having the same total yield and sound yield are placed in order by percentage of erect plants.

**Erect plants.** The percentage of erect plants in each entry on each field was estimated at the time of harvest. The ratings for erect plants show how the percentage of erect plants for each hybrid compared with the percentage of erect plants on the field as a whole. (Each rating is obtained by dividing the percentage of erect plants for that hybrid by the percentage of erect plants on the field as a whole and multiplying by 100.)

Lodging may have been due to rootworm damage, weak or rotted roots, corn borer damage, or weak stalks. Stalks broken above the ear were not considered lodged.

**Yield of grain.** To determine shelling percentage, all the ears from one replicate of each entry were shelled. From this shelled corn one sample was taken to determine the percentage of moisture at

harvest and another to determine the percentage of damaged kernels.<sup>1</sup> The percentage of damaged corn was determined according to the federal grain standards.

The total acre-yield was calculated as shelled corn containing 15.5 percent moisture, the upper limit allowable in No. 2 corn. The yield of sound corn was computed by deducting the amount of damaged corn from the total yield.

The rating of any hybrid for sound yield is the ratio, expressed as percentage, of the yield of sound corn from that hybrid to the average yield of sound corn from all the hybrids on the field.

**Height of ear.** Notes on comparative ear height were taken at harvest time. Each plot of each entry was placed in one of the five following categories: low, mid-low (midway between low and medium), medium, mid-high (midway between medium and high), and high. Beginning with low and continuing progressively to high, these terms were assigned numerical values from 1 to 5 to permit the averaging of the plots.

**Significance of yield differences.** Too much confidence must not be placed in the particular ranking of a hybrid in the following tables, for chance has played a part in determining its position. Unaccountable variability in the soil and conditions on the field will cause differences in yield that are not inherent in the hybrids themselves.

The part played by chance in the 1944 tests has been calculated for total yield by the mathematical procedure known as "analysis of variance." At the bottom of each table is stated the approximate difference there must be between any two entries in order for them to show a true inherent difference. Unless two hybrids differ by at least this amount, there is no assurance that one hybrid is inherently higher yielding than the other.

<sup>1</sup>For the Alhambra and Sullivan fields the moisture determinations were made with a Tag-Heppenstall moisture meter. Those for all the other fields were made with a Steinlite moisture tester.

**Readers are urged to note the difference necessary for significance, as shown for each test field, and to keep that difference constantly in mind in all comparisons of hybrids on that field.**

TABLE 5.—NORTHERN ILLINOIS: Mt. Morris, 1944

Rank	Entry	Acre-yield		Damaged corn in shelled sample	Mois- ture in grain at harvest	Erect plants	Rating for—		Compara- tive height of ear

<sup>a</sup>*Diabrotica duodecimpunctata* (F.) <sup>b</sup>High rating indicates better standing ability.

In percentage of plants leaning 30 degrees or more, a difference of less than 17.9 between any two entries is not significant.

A difference of less than 9.1 bushels between total yields of any two entries in this table is not significant.

## SOIL ADAPTATION TEST

The same nine double-cross hybrids that were tested at Urbana on soils of different productive levels in 1943 were tested again in 1944 in the same way (*Table 20*).

**Soils.** The two areas used for the tests are on the Agronomy south farm and differ in productivity as a result of long-continued use of different cropping systems. In the Southwest rotation a high state of productivity has been maintained by a systematic rotation of corn, oats, clover hay, and wheat with a red-clover catch crop. The South-Central area has been depleted of fertility by a rotation of corn, corn, corn, and soybeans. Both fields have received manure and phosphate. The predominating soil type on both fields is Sidell silt loam.

**Season.** Heavy spring rains delayed planting in 1944 as in 1943. The highly productive plot was planted on May 27, the less productive plot on June 7. Conditions after planting were generally favorable altho rainfall was below average thru July and August. Harvesting was delayed until the latter part of November.

**1944 results.** On the more productive field the average yield was 109.8 bushels an acre; on the less productive field it was only 54.8 bushels, just half as much (*Table 20*). The high yield is 9 bushels above and the low yield 10 bushels below comparable 1943 yields.

Contrary to previous tests, these nine hybrids in 1944 ranked the same on both fields. Illinois 972-1 and 246 were at the top, as they were on the more productive plots in 1943. The three less adapted hybrids, Illinois 784, 751, and 101, were the three low-ranking entries on both fields. Illinois 784 is

Table 20.—SOIL ADAPTATION TEST: Central Illinois, Urbana

7	Illinois Hybrid 751	50.9	50.0	1.7	20.0	77.4	114	92
9	Illinois Hybrid 101	44.5	43.8	1.6	19.7	64.9	96	81
	Average	54.8	54.1	1.3	20.5	67.8	...	...

A difference of less than 4.6 bushels between total yields of any two of the above entries is not significant.

very late-maturing for the central region of Illinois. Illinois 751 and 101 are much too early for the region of this test.

Between the six top-ranking adapted hybrids on the less productive plots there was a maximum difference of only 1.9 bushels an acre. On the more productive field the range was 6.1 bushels. There is thus very little reason, so far as yields are concerned, for choosing one of these hybrids over another. Differences in the percentage of erect plants are, however, very striking. In both tests Illinois 21 ranked highest in erect plants. Illinois 246 ranked relatively high on the better soil but went to the bottom of the list on the less productive field. On the more productive field 79.7 percent of the plants were erect; on the poorer field only 67.8 percent were erect. Thus physical factors other than yield need to be considered when judging of the adaptability of a hybrid to its environment.

Damage in the Southwest rotation area was due mostly to stalk breakage caused by the corn borer. In the South-Central area damage was due to lodging caused by rootworm injury.

The average of two years' results are given in Table 21.

Table 21.—TWO-YEAR AVERAGE SOIL ADAPTATION TESTS:  
Central Illinois, Urbana

Rank	Entry	Acre-yield		Damaged corn in shelled sample	Mois- ture in grain at harvest
		Total	Sound		
<b>HIGHLY PRODUCTIVE SOIL: Sidell Silt Loam, gently sloping phase, and Flanagan Silt Loam (Southwest rotation)</b>					
		<i>bu.</i>	<i>bu.</i>	<i>perct.</i>	<i>perct.</i>

6	U. S. Hybrid 13	60.1	62.4	2.0	18.9
7	Illinois Hybrid 784	59.9	59.5	.6	20.6
8	Illinois Hybrid 751	56.1	55.6	1.1	17.5
9	Illinois Hybrid 101	49.2	48.1	1.2	17.1
A difference of less than 4.0 bushels between total yields of any two of the above entries is not significant.					

## INTERPRETING RESULTS

A two-year test of any crop is of course a better basis for judging of its merit than a single year's record. For about two-thirds of the hybrids in the 1944 tests two-year summaries are given consolidating 1943 and 1944 results. Should a hybrid prove superior thru two years on more than one field, it may be considered not only high yielding but also wide in adaptation.

Yield of grain, while used as a basis for rating the hybrids in these tests, is not the only characteristic to consider when appraising a hybrid. Days required to reach maturity, resistance to ear rots, and ability to stay erect until harvest are also important. Even tho some of the fields in these tests were planted late and the grain, therefore, was not fully dry when harvested, the relative moisture content of one hybrid when compared with the others gives a good measure of its maturity.

The height at which the ear is borne on the stalk determines a hybrid's suitability for hand husking and also affects lodging resistance. This characteristic is influenced greatly by genetic constitution, soil fertility, and seasonal conditions.

Very few dropped ears were found in the 1944 test fields—so few that the records were not considered worth publishing.

## SUMMARY

A total of 237 corn hybrids were tested on seven fields in Illinois in 1944. Nine of these hybrids were included in an additional test to determine their response to soils of two different levels of productivity. Eighteen hybrids were tested for their response to seed treatment and their resistance to ear rot. Wet weather delayed corn planting, yet good stands were obtained on all the test fields. The results of these tests were briefly as follows:

1. The field having the highest average yield, 91.6 bushels an acre, was the one at Sullivan in Moultrie county in south-central Illinois. The average acre-yields of the other test fields were: Galesburg, 91.2 bushels; Mt. Morris, 89.1 bushels; Milford, 88.0 bushels; Dixon Springs, bottomland, 48.5 bushels; Alhambra, 32.9 bushels; and Dixon Springs, upland, 22.0 bushels. The average yield of corn for all seven fields was 66.2 bushels an acre, which contrasts with 45 bushels as the average for the state as a whole. (The locations of these fields are shown in Table 1, page 456, and in the map on the front cover.)

2. The general level of yields on all the fields, considering the conditions of the test, clearly indicates that most commercial seedsmen are producing high-yielding hybrid seed corn.

3. The few white hybrids tested in northern and north-central Illinois did not yield well in comparison with the yellow hybrids; but in south-central, southern, and extreme southern Illinois a number of them appeared to be very well adapted.

4. Chinch bugs did more damage to corn than any other insect in 1944. Damage on the Alhambra field is reflected in the lighter test weights of some of the hybrids.

5. For the Sullivan field in Moultrie county in south-central Illinois, records were made of lodging that resulted from the feeding of the corn rootworm. From 4.3 to 45.7 percent of the plants lodged 30 degrees or more from this cause, tho comparatively few hybrids developed the more severe lodging.

6. Stalk-breaking caused by infestation with the European corn borer was recorded for the Mt. Morris field in Ogle county in northern Illinois and for the Milford field in Iroquois county in east north-central Illinois. Appreciable amounts of lodging due to borer attack were found on both fields, but there was considerably less lodging at Mt. Morris.

7. Corn earworm feeding was severe on the Robbs field at Dixon Springs in Pope county in the extreme southern part of Illinois. The comparatively high percentage of damaged corn on this field was due

to ear rot fungi which invaded the kernels that had been injured by earworms.

8. Losses from diseases were, in general, about average in 1944. No one disease was especially outstanding.

9. Seed of 18 hybrids treated with Arasan gave yields 3.2 bushels an acre above the average of untreated seed. Damage from kernel rot in these same hybrids ranged from 3.37 to 7.72 percent.

10. The same nine double-cross hybrids tested on soils of two different levels of productivity in 1943 were tested again under similar conditions in 1944. The average yield of the hybrids on the soil of high productivity was 109.8 bushels an acre, while it was only 54.8 bushels on the soil of medium productivity. Contrary to previous tests, all nine hybrids ranked, on the basis of total yield, in the same order on both fields. There was very little difference between the yields of the six adapted hybrids on either field. The three hybrids less well adapted to central Illinois—namely, Illinois 784, 751, and 101—were the three low-yielding hybrids on both fields.

The two-year averages of the results on these two fields show for Illinois 246 a significant difference in relative ranking on the two fields. This hybrid yielded relatively high on the highly productive soil and comparatively low on the medium productive soil.

## PEDIGREES OF HYBRIDS

Following is a partial list of Experiment Station and U. S. hybrids. The performance of those that are starred is shown in this bulletin.
