67

68   **Abstract**

69   **Background**: The EU LifeCycle Project was launched in 2017 to combine, harmonise, and analyse

70   data from more than 250,000 participants across Europe and Australia, involving cohorts participating

71   in the EU-funded LifeCycle Project. The purpose of this cohort description is to provide a detailed

72   overview over the major measures within mental health domains that are available in 17 European and

73   Australian cohorts participating in the LifeCycle Project.

74

75   **Methods**: Data on cognitive, behavioural and psychological development has been collected on

76   participants from birth until adulthood through questionnaire and medical data. We developed an

77   inventory of the available data by mapping individual instruments, domain types, and age groups,

78   providing the basis for statistical harmonization across mental health measures.

79

80   **Results**: The mental health data in LifeCycle contain longitudinal and cross-sectional data for ages 0-

81   18+ years, covering domains across a wide range of behavioural and psychopathology indicators and

82   outcomes (including executive function, depression, ADHD and cognition). These data span a unique

83   combination of qualitative data collected through behavioural/cognitive/mental health questionnaires

84   and examination, as well as data from biological samples and indices in the form of brain imaging

85   (MRI, foetal ultrasound) and DNA methylation data. Harmonized variables on a subset of mental

86   health domains have been developed, providing statistical equivalence of measures required for

87   longitudinal meta-analyses across instruments and cohorts.

88

89   **Conclusion**: Mental health data harmonized through the LifeCycle project can be used to study life

90   course trajectories and exposure-outcome models that examine early life risk factors for mental illness

91   and develop predictive markers for later-life disease.

Background and Purpose

Effects of early life exposures on later life mental health are well known, but more research to understand and elucidate the pathways from stressors to outcomes is needed. The LifeCycle Project - EU Child Cohort Network, a Horizon 2020 project, is a pan-European and Australian initiative comprised of 19 pregnancy and birth cohorts, established to study exposure-to-outcome associations and trajectories across the life course (https://lifecycle-project.eu/).[1] In general, studies in LifeCycle aim to construct developmental trajectories, develop risk assessment models, measure developmental adaptations and evaluate mediating epigenetic effects to better understand the consequences of early-life exposures to stressors for risk factors and diseases in adulthood. The large sample sizes achieved through this consortium facilitate high statistical power needed for increased accuracy of estimates and more robust findings.

Mental health is one of the main outcomes within the LifeCycle Project.[1] While mortality rates for many non-communicable diseases have steadily declined in some populations over the past few decades, such as coronary heart disease[2,3] and chronic obstructive pulmonary disease,[4] the global burden of mental illness is on the rise.[5] The impact of mental illness on disability and socioeconomic prosperity is increasing around the world, and it is predicted that mental illness will contribute more to disability-adjusted life years (DALYs) than any other category of diseases by the year 2030.[6] An understanding of how mental health impacts and mediates disease risk and prognosis for other conditions is also beginning to emerge, with recent meta-analyses revealing significantly higher risks for cardiovascular[7] and metabolic[8] diseases linked to severe mental illness.

This cohort description focuses on the extensive work done to catalogue and harmonise variables related to cognitive, behavioural, and psychological development within the broader LifeCycle consortium.[1] It is well-recognised that experiences in early life play an important part in shaping later mental health[9] and the data within the LifeCycle Project permit analyses of these associations. LifeCycle includes many pregnancy and birth cohorts that prospectively collected data on offspring from conception and across different ages of child, adolescent, and adult development. The

124 availability of data from multiple follow-up assessments is essential for probing questions about

125 causality and linking early life stressors with later life mental health symptoms and outcomes.

126

127 The mental health studies in LifeCycle aim to investigate epidemiological interrelations between early

128 life exposures, behaviour, and cognition, with later mental and physical health. Towards this end we

129 have harmonised measures from 17 LifeCycle cohorts to enable studies that examine how

130 environmental stressors *in utero* and in early childhood affect, or are associated with, psychological

131 trajectories, behaviours, and mental outcomes throughout childhood, adolescence and adulthood.

132 Additionally, we are examining the nature and degree of mediation of these associations through

133 epigenetic changes and brain development (Figure 1). To our knowledge, the data compiled for these

134 studies within LifeCycle represents the largest ongoing consolidation of childhood behaviour,

135 psychopathology and cognition data to date, encompassing more than 200 multidimensional and

136 multi-informant established mental health measures collected from at least 250,000 participants.

140 disorders)

Cohorts, participants and follow-up

A total of 17 child-parent cohorts based in 13 countries are contributing with mental health data: Avon Longitudinal Study of Parents and Children (ALSPAC, United Kingdom), Born in Bradford (BiB, United Kingdom), EU Childhood Obesity Programme (CHOP, Germany/Italy/Spain/Poland/Belgium), Danish National Birth Cohort (DNBC, Denmark), Etude des Déterminants du développement et de la santé de l'Enfant (EDEN, France), Etude Longitudinale Française depuis l'Enfance (ELFE, France), Groningen Expert Center for Kids with Obesity Drenthe cohort (GECKO Drenthe cohort, The Netherlands), the Generation R Study (Generation R, The Netherlands), Helsinki Birth Cohort Study (HBCS, Finland), Infancia y Medio Ambiente (INMA, Spain), The Norwegian Mother, Father and Child Cohort Study (MoBa, Norway), Northern Finland Birth Cohorts (NFBC1966/1986, Finland), Nascita e INFanzia: gli Effetti dell'Ambiente (NINFEA, Italy), The Raine Study (Australia), Rhea Mother & Child Cohort Study (RHEA, Greece), and the Southampton Women's Survey (SWS, United Kingdom).
Figure 2. Geographic distribution and sample sizes of cohorts in LifeCycle contributing mental health data

159 The geographic coverage is broad, spanning across much of northern, western, central and southern

160 Europe as well as Western Australia (Figure 2). Mental health data from more than 250,000 children

161 are available (as of June 2021), including either mother-child or mother-father-child cohorts, and the

162 study population is diverse with respect to the age of the participants, cohort types, and data collection

163 periods (Table 1). As described elsewhere for the LifeCycle consortium, most of the cohorts in the

164 LifeCycle project (ALSPAC, CHOP, DNBC, EDEN, GECKO, HBCS, INMA, MoBa,

165 NFBC1966/1986, NINFEEA, RHEA, and SWS) predominantly represent ethnic groups from the

166 background population (more than 95% European/White), but certain cohorts like BiB, ELFE, The

167 Generation R Study, and The Raine Study have significant representation of other ethnic groups as

168 well.[10]

169

170 **Table 1. Summary characteristics of LifeCycle cohorts participating with mental health data**

Cohort	Location of Coordinating Centre	Cohort Type	Data collection period	Recruitment	N (Live Births)
ALSPAC[11,12]	Avon, United Kingdom	Population-based	1990-present	Pregnancy	14,953
BiB[13]	Bradford, United Kingdom	Population-based	2007-2010	Pregnancy	13,786
CHOP[14]	Belgium (Liege, Brussels), Germany (Munich, Nuremberg), Italy (Milano), Poland (Warsaw), Spain (Reus, Tarragona)	Mixed (Randomised controlled intervention trial (first year) with birth cohort)	2002-2015	First 8 weeks of life	1,678
DNBC[15]	Copenhagen, Denmark	Population-based	1996-present	Pregnancy	96,804
EDEN[16]	Nancy and Poitiers, France	Population-based	2003-2017	Pregnancy	1,907
ELFE[17]	Paris, France	Population-based	2011-present	Birth	18,329
GECKO[18]	Drenthe, The Netherlands	Population-based	2006-present	Pregnancy	2844
The Generation R Study[19,20]	Rotterdam, The Netherlands	Population-based	2002-present	Pregnancy	9,749
HBCS[21]	Helsinki, Finland	Population-based	1934-present	Birth	13,345
INMA[22]	Sabadell, Spain	Population-based	2004-present	Pregnancy	622
	Valencia, Spain	Population-based	2003-present	Pregnancy	787
	Gipuzkoa, Spain	Population-based	2006-present	Pregnancy	612
MOBA[23]	Oslo, Norway	Population-based	1999-present	Pregnancy	113,564
NFBC1966[24]	Oulu, Finland	Population-based	1966-present	Pregnancy	12,058
NFBC1986[25]	Oulu, Finland	Population-based	1985/1986-present	Pregnancy	9,432
NINFEA[26]	Torino, Italy	Population-based (Internet-based recruitment)	2005-present	Pregnancy (Internet-based recruitment)	6,816
The Raine Study[27]	Perth, Australia	Population-based (Randomised assignment to multiple ultrasounds during pregnancy)	1989-present	Pregnancy	2,868
RHEA[28]	Crete, Greece	Population-based	2007-present	Pregnancy	1,458
SWS[29]	Southampton, United Kingdom	Population-based	1998-present	Pre-pregnancy	3,158

171

172 The participating cohorts include child participants with follow-up data ranging from birth until

173 adulthood (Table 2). Questionnaires, medical records, doctor diagnoses and registries were variably

174   used across the cohorts to collect data at different ages, but all of the cohorts collected baseline data

175   during pregnancy or at birth, and included a follow-up data collection at least once by the time the

176   child participant was 24 months of age. Although the regularity of follow-up differs substantially

177   across cohorts, ranging from annually to many years apart, at least half of the cohorts performed some

178   type of follow-up data collection for all incremental age groups up until 6 years of age. The

179   overlapping age ranges enable comprehensive comparative analyses of mental health constructs

180   between and within the populations to which these index children belong.

Table 2. Age ranges and sex (% male:female) of participants during assessment in LifeCycle cohorts

Cohort	Baseline (no. live births)	Age of child at assessment (years)

182 [a]ALSPAC follow-up data is based on number of parents completing at least some of the questionnaire(s) on young person up to age 7 years, and number of children attending clinic from age 7 years and onwards
183 [b]CHOP follow-up data is based on number of children with at least one anthropometric measurement at the considered age
184 [c]DNBC follow-up data at 5 years based on a subsample, selected based on parental alcohol characteristics
185 [d]Parent-reported data
186 [e]Self-reported data
187 [f]DNBC data collection for 18-year follow-up is currently ongoing
188 [g]EDEN follow-up data is based on number of children with at least one neurodevelopment assessment at the considered age
189 [h]Teacher-reported data
190 [i]Clinical data
191 [j]NINFEA baseline data refers to no. pregnant women recruited

Main outcome measures

Psychological, motor and cognitive measures

Mental and cognitive disorders comprise some of the most frequently diagnosed conditions in children under 18 years of age. The combined data resource will contain information pertaining to the children from more than 200 mental health measures, covering eight clinical domains across 60 dimensions (Table S1). A majority of these measures assess domains under a broad banner of 'mental health', encompassing psychological functions, cognitive and executive functions and psychological development (67.0%; 136 of 203), covering dimensions such as neurodevelopmental disorders, internalising and externalising symptoms, temperament and mental diagnoses. Further domains include language skills (31.0%; 63 of 203), executive functions (29.1%; 59 of 203), memory (11.3%; 23 of 203) and general intelligence (8.4%; 17 of 203) (Table S1). There are many commonalities between mental health domain-types and significant overlap in the age groups with measures in specific domains (Figure 3). This makes it possible to harmonise the data.[30] Most of the cohorts continuously follow up their participants, and the availability of harmonised data will tend to increase with time.
**Figure 3. Overview of overlap in LifeCycle mental health, behavioural and cognitive domains across age**

Basic illustration of the range of developmental domains and participant ages for data in the LifeCycle Project.

There are a number of approaches to harmonise data and several of these have been described and successfully implemented in large collaborations.[31,32,33,10] The LifeCycle Project has developed a protocol to generate harmonised variables across a selection of important cognitive and mental health domains. This harmonisation approach creates standardised scores and percentiles for important domains such as internalising and externalising symptoms, ADHD and ASD symptoms and diagnosis, and language and motor functions. Percentiles and standardised scores were used as they allow the pooling of mental health outcome data collected using different scales or instruments. One of the biggest harmonisation challenges this project faced was obtaining a thorough inventory of the available mental health data in individual cohorts, which was overcome by mapping the available data by instrument, measure, age group, and domain. A subset of cohorts has also employed items from the same mental health, cognitive and motor function measures, and these data can be pooled or co-analysed without the need for harmonisation (Figure 4). All of the measures harmonised thus far by age and cohort can be found in the LifeCycle online catalogue (https://catalogue.lifecycle-project.eu/).

Figure 4. Overview of overlap in mental health and cognitive measures in the LifeCycle cohorts providing mental health data

Summary of overlapping measures and age ranges in participating cohorts. The full list of available measures (including non-overlapping) are described in supplementary table 1.

(ANT: Attention Network Task; ASQ: Ages and Stages Questionnaire; BAS: Behavioural Approach System; BDI: Becks Depression Inventory; BRIEF: Behaviour Rating Inventory of Executive Function; BSID: Bayley Scales of Infant Development; CAST: Childhood Asperger Syndrome Test; CBB: CogState Brief Battery; CBCL: Child Behaviour Checklist; CPRS-R: Revised Conners' Parent Rating Scale; DAWBA: Development and Well-Being Assessment; DDST: Denver Developmental Screening Test; DISC-IV: Diagnostic Interview Schedule for Children; DST: Digit Span Test; FTT: Finger Tapping Test; GMDS: Griffiths Mental Development scales; GPT: Grooved Pegboard Test; M-CHAT: Modified Checklist for Autism in Toddlers; MB-CDI: MacArthur-Bates Communicative Development Inventories; N-Back: Working Memory Test; NEPSY-II: Developmental NEuroPSYchological Assessment, Second Edition; PLIKS: Psychosis-like symptoms measure; RPM: Raven's Progressive Matrices; SDMT: Symbol Digit Modalities Test; SDQ: Strengths and Difficulties Questionnaire; TEA-ch: Test of Everyday Attention for Children; TMT: Trail Making Test; TRF: Teacher Report Form; WASI: Wechsler Abbreviated Scale of Intelligence; WPPSI: Wechsler Preschool and Primary Scale of Intelligence; YRBSS: Youth Risk Behavior Surveillance System; YSR: Youth Self-Report).

13

279 *Early-life exposures – lifestyle, migration, socioeconomic, and urban environment*

280 The LifeCycle online catalogue[10] also contains information on harmonised data on diverse measures of

281 exposures early in life. These will enable the analysis of risk models for mental health that assess the

282 nature and impact of indirect and direct exposures experienced in early life, and comorbidities with

283 adverse mental health symptoms and other health conditions. Comprehensive exposure-outcome

284 analyses will also be used to develop predictive markers for mental health in children and adolescents,

285 which may help shape the prediction of mental disorders, allowing for targeted early intervention.

286

287 *Mediating Pathways - Brain Development*

288 Early life is a particularly vulnerable time-window for brain development. The vital stages of

289 neurogenesis, proliferation and migration occur almost exclusively during foetal development, and

290 experience-dependent brain connectivity (i.e. myelination) is largely shaped and completed in early

291 childhood.[34] Research-based evidence has repeatedly linked brain structure, volume, and connectivity

292 indicators to a number of behavioural and cognitive outcomes.[35,36,37] However, study samples are often

293 limited in size and population diversity, and only few longitudinal studies exist.[38] A subset of cohorts

294 in LifeCycle have participant data on structural brain imaging (ALSPAC n=950; Generation R

295 n≈4000;[39] NFBC1966 n=1000; NFBC1986 n=600), and will be contributing information on

296 neuroanatomical markers such as total brain volume, cortical grey matter, white matter volume,

297 ventricular volume, and volumes of subcortical brain structures including the hippocampus and

298 amygdala. In addition, structural and functional connectivity metrics have been assessed. Data have

299 been collected through neuroimaging techniques, such as foetal ultrasound and Magnetic Resonance

300 Imaging (MRI) in childhood and /adulthood MRI. These data enable LifeCycle to describe changes in

301 structural and functional development of the brain from foetal life and infancy, and to subsequently

302 associate this brain development in early life with psychopathology outcomes in childhood,

303 adolescence and adulthood.

304

305

306

14

Mediating Pathways - Epigenetics

An increasing number of studies are beginning to demonstrate the importance of epigenetic
modification in mediating the risk of disease, including mental health outcomes. Epigenetically-
modified loci have been linked to a wide range of mental disorders such as schizophrenia,[40] as well as
childhood onset disorders such as ADHD,[41] and ASD,[42] but conflicting and non-replicated associations
mean that the causal relationships remain poorly understood.[43] LifeCycle mental health studies can
currently analyse DNA methylation data on 14,368 offspring cohort participants (Figure 5), measured
at birth (cord or placenta blood; N=7,783), childhood (0-12 years; N=3,055), adolescence (12-18
years; N=2,680), or adulthood (>18 years; N=850). Six of the thirteen contributing cohorts
additionally contain longitudinal epigenetic data [ALSPAC, CHOP (multiple age groups in
childhood), EDEN, Generation R, INMA, and RHEA]. The particular focus will be to identify
epigenetic mechanisms that mediate the effect of early life exposures on behavioural and cognitive
development, as well as mental health outcomes such as ASD, ADHD, depression and anxiety. This
means it will be possible to track epigenetic changes in participants with behavioural and/or
neurodevelopmental outcomes across time, and study causal relationships between environmental
exposures in pregnancy or early life and later-life mental health outcomes mediated by DNA
methylation.

Figure 5. Overview of sample sizes for DNA methylation data in the offspring from birth to adulthood

Circle sizes are proportionate to the DNA methylation sample sizes as indicated in the scale at the bottom of the figure.

*Numbers relevant as of June, 2021 (sample processing and data collection is ongoing in several LifeCycle cohorts)

Framework for collaborative analyses

LifeCycle aims to perform most of the analyses through DataSHIELD.[44,45] With the recent launch of

the platform and its analytical features for use with LifeCycle harmonised data, a number of novel

collaborative studies have begun to form within the theme of mental health. Examples of planned and

ongoing exposure-outcome analyses include infant feeding patterns and school-age externalising

behaviours, maternal smoking in pregnancy and adverse child behaviours, associations between sleep,

behaviour and cognition, sibling effects and prematurity, and socioeconomic inequalities and general

mental health trajectories. Results from these studies are currently pending, but they have already

shown that independent participant data resources have been successfully harmonised and can be co-

analysed. The quantity and breadth of mental health and cognitive data available that have been

mapped and harmonised by the LifeCycle mental health research group is a singular resource to enable

developmental studies of mental health. These data will play an important role in replicating previous

353 findings with an enhanced statistical power, expanding upon previous associations through larger and

354 more diverse samples, and in the development of novel models to describe how multi-faceted early-

355 life exposures can shape and influence the landscape of mental health in later life.

356

357 **Strengths and limitations**

358 There are many strengths inherent in large consortia such as LifeCycle.[1] Key among these is that

359 LifeCycle is building the EU Child Cohort Network, a sustainable research network that will enable

360 continued exploitation of the LifeCycle data, metadata and collaborative progress beyond the usual

361 timelines of a funded grant. Another important strength is the ability to study age differences and age-

362 related mental health and cognitive changes; this developmental aspect will help to understand the

363 long- and short-term consequences of early life exposures, and how other factors such as epigenetic

364 changes may mediate later health outcomes. Geographic diversity is also a key feature; it provides

365 enhanced location coverage and generalizability of results, and also facilitates intra- and inter-

366 population comparisons. This makes it possible to make more reliable causal inferences due to

367 different confounding structures.

368

369 The number of critical mental health domains covered is another strength, allowing for exposure-

370 outcome research into many important and well-studied areas within this field. The availability of the

371 harmonisation protocols, coupled with the extensive overview of mental health measures, including

372 detailed information on the dimensions and age ranges across cohorts, provides users with an

373 integrated catalogue of psychological, cognitive, and psychomotor data in participating cohorts.

374 Furthermore, the use of DataSHIELD enables a flexible and data-secure approach that allows new

375 cohorts and centres to link into the analysis network and contribute with their own data, as well as the

376 addition of newly harmonised data as these are collected and updated. This open-source analysis

377 platform "takes the analysis to the data, not the data to the analysis", providing researchers with the

378 ability to remotely analyse data from multiple datasets without being able to access the data itself.[45,46]

379 Removing the need to physically share data externally means participating cohorts bypass ethical

380 concerns related to the protection of privacy and other issues that arise when participant data are being

381 sent internationally to multiple users, and thus addresses some important ethico-legal considerations

382 that are often associated with individual-level data sharing and analysis.

383

384 The heterogeneity of the psychological and cognitive measures available presents a potential

385 limitation. Depending on the specific research question under investigation and measurement

386 equivalence of constructs between different instruments, robust harmonisation[30,32] of certain measures

387 may not be possible or may be limited to a small number of cohorts. This reduces the sample size or

388 the range of participant ages that are possible to include. Within-country geographical bias of many of

389 the cohorts may also present a weakness. Specifically, the urban-centric nature of many of the studies

390 could mean that the generalizability of findings will be somewhat skewed, and the population-level

391 inferences will need to take this bias into account. Furthermore, DNA methylation and brain imaging

392 data are only available for less than 10% of total study participants. These smaller sample sizes may

393 limit the number and strength of associations that can be found, as well as the distribution of

394 participant ages and geographic and ethnic origins. However, the cohort studies are continuously

395 expanding and adding new data on their participants, including phenotypic, genetic, epigenetic and

396 biological data. The collaborative groundwork laid by LifeCycle will make it possible to continue

397 building upon the analyses that have been performed, and help to mitigate some of the limitations that

398 have been described.

399

400 **Data Access**

401 LifeCycle has developed an application procedure for data use proposals as described by Jaddoe et al.[1]

402 It should be noted that approvals for data use and associated fees remain under the purview of the

403 participating cohorts. This is the case regardless of whether one applies through LifeCycle or directly

404 to the cohort, and these practices may vary across cohorts. The project strives to conduct as many

405 analyses as possible within DataSHIELD. DataSHIELD is freely available to download and use

406 (http://www.datashield.ac.uk/). This enables external cohorts to collaborate with LifeCycle and

407 perform co-analyses. For more information, please visit the official website for the LifeCycle Project

408 (https://lifecycle-project.eu/), or refer to the consortium design paper.[1]

409 In some cases, data sharing and transfer agreements will need to be developed. These may vary due to

410 country-specific practices and restrictions as outlined by local General Data Protection Regulation

411 (GDPR) legislation. Application procedures directly to cohorts for data can be found at the following

412 websites:
