Abstract

Satisfiability problem is a well-known NP-complete problem. It consists of testing whether the clauses in a Conjunctive Normal Form can all be satisfied by certain consistent assignment of binary values to variables. If it is consistent, the problem is said to be satisfiable; otherwise, it is unsatisfiable. The 3-SAT randomized problem is the smallest NP-complete problem in SAT. In the literature, many transformations have been proposed in converting the satisfiability problem into an integer programming problem. These transformations usually create extra variables and constraints that would enlarge the problem size.

In this thesis, we propose a new transformation method with no extra variables introduced and a single surrogate constraint is resulted at the end of the process. This singly-constrained zero-one polynomial problem can be then solved by certain solution techniques in integer programming problem, such as branch-and-bound methods. We suggest some branch-and-bound algorithms to tackle the resulted singly-constrained zero-one polynomial problem. Revised branch and bound rules are proposed to improve the efficiency of a basic algorithm. Analytical results show that the revised branch-and-bound algorithm has a great improvement compared with the basic one, in terms of the computation time and the number of backtracking.

摘要

可滿足性問題 (Satisfiability problem) 是一個著名的NP 完全問題，它是指是否存在一種對一組布爾變量的賦值使所給的由若干個子句組成的合取範式的值為真。若這種賦值方法是存在的，則問題稱為可滿足的；反之，則稱不可滿足的。儘含三個子句的隨機可滿足性問題是SAT中一個最小規模的NP完全問題。有關文獻中提出了許多把可滿足性問題轉換成整數規劃問題的方法，遺憾的是這些方法通常會產生額外的變量和約束，從而擴大了問題的規模。

本文建出了一種新的轉換方法，它以一個替代約束代替原有所有約束而不產生額外的變量。轉換後得到的單約束0-1多項式問題可用分支定界法來求解。本文首先提出了一些基本的分支定界算法，進而提出了改進的分支和定界的法則來提高運算的效率；對運算結果的分析顯示了改進的分支定界算法，較之基本的方法，無論在計算的時間上，還是在回溯的次數上，均有極大的改善。

Acknowledgements

I would like to express my deepest gratitude to my supervisor Professor Duan LI for his guidelines and suggestions. Without his advice, this thesis cannot be completed.

I would also like to thank a lot of my friends, Dr. Sha Dan, Chu Kwok Fai, Tommy Lee, Jacky Wong, Ada Ng, Cindy Lam, Gary Lee, Jason Choi, Chiu Chun Hung, Ada Luk, Jessica Hui, Paul Fung, Wong Kam Lai, Yvonne Sho, Sunny Man and Bernard Hui. They bring me much happiness in leisure time and help me a lot in study. In this two-year graduate study, we share many unforgettable memories and a fruitful university life.

Finally, I may express my deepest thanks for the God. He enlight me and set me free from the sadness and anxiety. The support and encouragement from my fellows activate the motion of my research.

Chapter 1

Introduction

1.1 Satisfiability Problem

The propositional satisfiability problem (SAT) has been classified as the first NP-complete problem. It consists of testing whether the clauses in a propositional formula F in Conjunctive Normal Form (CNF) can all be satisfied by some consistent assignments of true values (0 or 1) to variables. If it is the case, F is said to be *satisfiable*. Otherwise, F is *unsatisfiable*. Moreover, if each clause exactly contains r literals, the subproblem is called r -SAT problem. 3-SAT is the smallest NP-complete subproblem of SAT with its computation time being $O(2^n)$ while 2-SAT problem is solvable in polynomial time [1, 2, 3, 4].

1.2 Motivation of the Research

Besides Davis-Putman-Loveland procedure and *SATZ* methods, satisfiability problems can be solved by integer programming methods or semidefinite programming methods. After transforming the SAT problem into an integer programming prob-

lem, the performance in solving the transformed problem may not be as good as that of the original.

Warren and Alain [5] suggested to convert a pseudo-Boolean function into constrained 0-1 polynomial problem. Lagrangian relaxation and roof duality techniques can solve the non-convex polynomial problem by testing the duality gap between the primal problem and its relaxation. The resulting objective value can be viewed as the upper bound of the problem if the duality gap exists.

The above consideration motivates us to figure out a procedure to convert the CNF-SAT problem into an integer programming formulation. In our research, Branch-and-Bound algorithm can be used to solve the zero-one singly-constrained polynomial problem. Thus, we need to develop our branch rule and bound rule that are suitable for our problem. The continuous relaxation model from [5] can be used to find the upper bound of the subproblem. The existence of duality gap can be checked by verifying whether the solution is an integer instead of the consistency of the 0-1 quadratic posiform suggested by [5]. As a result of studying the branching rules, a better understanding in solving SAT by an IP formulation is achieved.

1.3 Overview of the Thesis

The thesis is organized as follows. Chapter 2 gives a brief review of the satisfiability problem and its solution techniques. Methods like DPL, *SATZ* and SDO are discussed and several SAT solvers are listed in the last section. Integer programming, in particular, zero-one programming and its continuous relaxation are important techniques adopted in this thesis. We provide some basis on them in Chapter 3. Branch-and-Bound methods, Cutting plane methods, duality methods and heuristic methods

are discussed. Solvers found on the internet are listed also.

We present a two-step transformation for converting an original 3-SAT problem into a singly-constrained zero-one polynomial problem in Chapter 4. The first step of the transformation changes m SAT clauses into m integer programming constraints where $m = n * 4.25$ and n is the number of variables in the original problem, while the second step constructs the resultant zero-one singly-constrained polynomial problem from the transformed integer constraints. In Chapter 5, we describe a basic branch-and-bound method.

Chapter 6 defines a revised bound rule for the branch-and-bound method. The revised bound rule is based on the continuous relaxation of the polynomial integer constrained maximization problem shown in [5]. We use a dual simplex method to figure out the bound for the subproblem after converting the integer singly-constrained polynomial problem into a continuous constrained maximization problem. *Cplex* is a solver used to implement the revised bound rule. The example in Chapter 5 is tested for a determination of the improvement. A revised branch rule is presented in Chapter 7. We consider a similar formula as in [6] to set the weight for variables so as to find out the branching variable at each iteration. The example in both Chapter 5 and 6 is used here again to examine the revised branch-and-bound method.

Experimental results are reported in Chapter 8. We compare the performance between the basic branch-and-bound method and the revised one with different sample sizes. *SATZ* is also used to compare with the two branch-and-bound methods. Finally, we conclude the thesis in Chapter 9 by summarizing our contributions and listing some possible directions for future research.

Chapter 2

Constraint Satisfaction Problem and Satisfiability Problem

This chapter provides the background of the thesis. Satisfiability (SAT) problem was the first problem shown to be NP-complete [7]. SAT is a cornerstone of computational complexity theory, and thus is commercially important since thousands of practical combinatorial problems would benefit from a highly efficient SAT solver. Its applications include graph coloring, Boolean N-queens induction, circuit diagnosis and scheduling problem [8, 9]. In this chapter, we will define what a satisfiability problem is and how to solve the SAT problem. Also, we will list some solvers in the last section that have been released recently.

2.1 Constraint Programming

Constraint Programming is built upon constraints and constraint solving [10]. The three most important types of constraints in constraint programming are *arithmetic constraints*, *tree constraints* and *finite domain constraints*. There are three funda-

mental operations in solving a constraint programming problem. First, we need to determine whether a constraint is *satisfiable*. Then, we use *simplification* to rewrite a constraint in a form that makes its information more apparent. Last, we find out the “best ” solution under some conditions through an *optimization* method.

Primitive constraint consists of a constraint relation symbol from its domain, D , together with the appropriate number of arguments [10]. They are constructed from the constants, functions of D and other variables. A *user-defined constraint* is a constraint in the form of $p(t_1, t_2, \dots, t_n)$ where p is an n -ary predicate and t_1, t_2, \dots, t_n are expressions from the constraint domain [10]. A *formula* is a primitive constraint involving variables that return the value of True or False. A *literal* is either a primitive constraint or a user-defined constraint [10]. In this thesis, the literals we considered are primitive constraints.

A *Constraint Satisfaction Problem* (CSP) consists of a constraint C over variables x_1, x_2, \dots, x_n and a domain D that maps each variable x_i to a finite set of values, written $D(x_i)$, that are allowed to take. The CSP can be used to represent the constraint $C \wedge x_1 \in D(x_1) \wedge \dots \wedge x_n \in D(x_n)$, [10]. Complete search strategies for constraint satisfaction problems are based on propagate-and-branch and they only assign integral values to the variables whose domain includes finite integers [9]. The search starts from a partial assignment of the variables. The power of CSP methods stems from strong propagation algorithms (eg. arc-consistency) that rule out all variable values that are known to be inconsistent with the current partial variable assignment and the set of constraints (local consistency). Search in CSP progresses in the space of partial variable assignments where variable values are assigned with the goal to eventually assign one value to *every* variable, such that the solution is optimal. Hence, the search in CSP maintains integrality and local consistency, but

relaxes totality, i.e. require that all variables be assigned one value.

A CSP can also be defined as below. A CSP consists of a set of variables, each with a finite possible value (domain), and a set of constraints which the values assigned to the variables must satisfy, [11]. Some discrete optimization problems in operational research can be also formulated as constraint satisfaction problems. In an optimization constraint satisfaction problem, there is an objective. Each time a solution to the CSP is found, a new constraint is added to ensure that any future solution must have an improved value of the objective, and this continues until the problem becomes infeasible. The last solution found is the optimal solution of the problem.

2.2 Satisfiability Problem

Consider n propositional variables $X = \{x_1, \dots, x_n\}$. Let $L = \{x_1, \bar{x}_1, \dots, x_n, \bar{x}_n\}$ denote the set of corresponding literals, where $\bar{x}_i = 1 - x_i$ denotes the *complement* of x_i . Let $x = (x_1, \dots, x_n) \in B^n$, where $B = \{0, 1\}$, denote the vectors of binary assignments to the propositional variables. A *clause* is the disjunction of a subset of the literals, and a *Conjunctive Normal Form* (CNF) is a Boolean formula of the form

$$\Phi_{\mathcal{C}}(x) = \bigwedge_{C \in \mathcal{C}} (\bigvee_{u \in C} u),$$

where $\mathcal{C} \subseteq 2^L$ is a family of clauses, [12].

The satisfiability (SAT) problem for Boolean formulas in conjunctive normal form (CNF) was the first problem that was shown to be NP-complete, [7, 13, 14]. It consists of finding a binary assignment $x^* \in B^n$ satisfying all the clauses of a given CNF F , i.e., $\Phi_F(x^*) = 1$. It tests whether clauses in F can all be satisfied by some consistent assignment of true values (0 or 1) to variables, [15, 16]. F is said to be satisfiable if

there exists a feasible assignment. Otherwise, F is said to be unsatisfiable. Moreover, if each clause exactly contains r literals, the subproblem is called r -SAT problem. It has been revealed that 2-SAT problem is solvable in polynomial time [1, 2, 3, 4] and Even, Itai and Shamir [17] outlined a linear-time algorithm for 2-SAT. Schaefer [18] also claimed a polynomial time bound for an evaluation problem with 2-SAT although he did not prove it. However, 3-SAT is the smallest NP-complete subproblem of SAT where its computation time is within $O(2^n)$. On the other hand, if the ratio of the number of clauses to the number of variables is approximately equal to 4.25 for random 3-SAT problem [19, 20], these problems are very difficult to be solved.

2.3 Methods in Solving SAT problem

There are many different kinds of methods in solving *Conjunctive Normal Form Satisfiability (CNF – SAT)* problem. The best complete method to solve SAT problems is *Davis-Putnam-Loveland (DPL)* procedure.

2.3.1 Davis-Putnam-Loveland Procedure

Davis-Putnam-Loveland (DPL) procedure was defined by Martin Davis, George Logemann and Donald Loveland in 1962 [21, 15]. The DPL procedure was based on the idea in [22]. The algorithm of [22] consists of two interlocking parts. The first part is the *QFI – Generator* that generates a growing propositional calculus formulas in conjunctive normal form which are called the “quantifier-free lines”. The second part is the *Processor* that tests the consistency of these propositional calculus formulas at regular stages in its “growth”. This test is proceeded by first eliminating *one-literal* clauses and then atomic formulas all of whose occurrences are positive or negative.

Finally, the remaining atomic formulas are to be eliminated by using the *Rule for Eliminating Atomic Formulas*. This Rule can be formulated as

$$\text{Rule III } (A \vee p) \ \& \ (B \vee \bar{p}) \ \& \ R \quad [21, 22]$$

where A , B and R are free of p . This can be done by grouping the clauses containing p and crossing out the occurrences of p to obtain A , grouping the clauses containing \bar{p} and crossing out the \bar{p} to obtain B , and grouping the remaining clauses to obtain R . Then, F is consistent if and only if $(A \vee B) \& R$ is consistent.

The DPL procedure replaces the *Rule III* by *Splitting Rule* which is defined as

$$\text{Rule III}^* (A \vee p) \ \& \ (B \vee \bar{p}) \ \& \ R \quad [21]$$

where A , B and R are free of p . Then F is inconsistent if and only if $A \& R$ and $B \& R$ are both inconsistent. *Rule III*^{*} is more powerful because *Rule III* can easily incorporate large number and long length of the clauses in the expression. Many duplicated and redundant clauses are allowed to present. Also, *Rule III* seldom yields new *one – literal* clauses, whereas *Rule III*^{*} often does.

2.3.2 SATZ by Chu-Min Li

The Davis-Putnam-Loveland procedure has been so far the best complete method to solve SAT problems. It constructs a binary search tree for solving F and each recursive called constitutes a node of the tree. In [15], Chu-Min Li indicated that random 3-SAT problems become difficult to solve on average when the ratio of clause number to variable number is approximately equal to 4.25 [19, 20]. He explained that the shape of a search tree is highly related to the width of a search tree rather than the mean height of a search tree. The mean height of the class of Hard problems is the same as that of the class of Easy problems. However, the width of the class of

Hard problems is substantially larger than that of the class of Easy problems. It is difficult to distinguish satisfiable and unsatisfiable problems here because they give the same shape of figures. Also, the widest level of a search tree is at the mid-depth approximately equal to $n/20$ where n is the number of variables in the problem.

SATZ by Chu-Min Li is a DPL procedure that branches on the variable that would reduce the largest number of clauses on F at each iteration. Let $w(x)$ be the number of clauses reduced when x is assigned 1 and $w(\bar{x})$ be the number of clauses reduced when x is assigned 0. Then x is weighted by the equation suggested by Freeman [6],

$$H(x) = w(x) * w(\bar{x}) * 1024 + w(x) + w(\bar{x}).$$

From here, we know that the product term $w(x) * w(\bar{x})$ gives more information in selecting the branching variable in order to balance the search tree. The value of 1024 may be used for a quicker multiplication since $1024 = 2^{10}$. For example, there are 10 clauses reduced when x_1 is assigned 1 and 6 clauses reduced when x_1 is assigned 0. And there are 8 clauses reduced when x_2 is assigned 1 and 8 clauses reduced when x_2 is assigned 0. We know that the weights of x_1 and x_2 are 61456 and 65552 respectively. We would choose x_2 as the next branching variable.

On the other hand, Chu-Min Li has made some improvements to DPL procedure. In order to speed up a DPL procedure, Li proposes to reduce the width of a search tree instead of reducing its mean height. That means, his procedure could reach a dead-end as early as possible. He had 2 suggestions. First, his procedure would prepare and generate more and stronger constraints (A constraint is stronger if it suppresses more solutions). If F has n variables, it has 2^n possible solutions. Two binary clauses sharing a complementary literal, like $x_1 \vee x_2$ and $\bar{x}_1 \vee x_3$, remove 2^{n-1} solutions while two binary clauses sharing an identical literal or having no common variable, such as $x_1 \vee x_2$, $x_1 \vee x_3$ or $x_1 \vee x_2$ and $\bar{x}_3 \vee x_4$, remove $2^{n-1} - 2^{n-3}$ and $2^{n-1} - 2^{n-4}$ solutions

respectively. Obviously, binary clauses sharing complementary literals remove much more solutions and have more chances to lead to a dead-end where all solutions are removed. So the DPL procedure would branch next on a variable that generates more binary clauses sharing complementary literals. Therefore, the weight of the literal x would be changed to

$$w(x) = \sum_{l \vee l' \text{ is produced by } x=1} [f(\bar{l}) + f(\bar{l}')],$$

where $f(\bar{l})$ is the number of binary occurrences of \bar{l} in F if there is a sufficient number (10 as suggested by Li) of binary clauses in F , otherwise it is the number of weighted occurrences of \bar{l} in F . $w(\bar{x})$ is similarly defined. Li [15] then obtains the weight of variable x by replacing the value of both $w(x)$ and $w(\bar{x})$ in Freeman's formula [6].

Li also suggests to use *looking further forward* to search a dead-end. *Unit propagation* is a look-ahead¹ searching technique. If the satisfaction of a literal l reduces many clauses, i.e., it introduces many strong constraints by unit propagation, it probably leads to an imminent dead-end which can be reached by further unit propagations. The idea is that if $UnitPropagation(F \cup \{l\})$ reduces more than T (it is fixed to 65 for hard random 3-SAT problems [15]) clauses, for every variable y in the newly produced binary clauses occurring both positively and negatively in binary clauses, $UnitPropagation(F \cup \{l\} \cup \{y\})$ and $UnitPropagation(F \cup \{l\} \cup \{\bar{y}\})$ are executed. If both propagations reach a dead-end, \bar{l} should be satisfied. These two propagations are called *unit propagations of second level*. This has a great impact on the size of a search tree. This keeps a balance in the search tree for the branching variable x . It is because if $w(x) \gg w(\bar{x})$ or $w(\bar{x}) \gg w(x)$, x will not be selected as a branching variable. Therefore, the formula for selecting the branching variable would be more powerful.

¹Please refer to Appendix A for details

In addition, Li figures out that branches on a variable randomly among the *best* variables may provide a better performance if it creates simpler subproblems. He found that the randomized version of *SATZ* could solve the benchmark problem 2670-400 in UCSC in 95 seconds while the revised version of *SATZ* took more than 7200 seconds to solve the problem [15]. Nevertheless, a constraint hypothesis that considers unit propagations in deeper branches might reach a dead-end faster than simplified hypothesis that he has used. However, more constraints might be generated during the unit propagation process.

2.3.3 Local Search for SAT

Local search strategies have recently been used in solving propositional satisfiability problem [9]. It searches a satisfying variable assignment for a set of clauses. It moves locally to “flip” variables that are chosen according to a randomized greedy strategy. A randomized algorithm is used to select a starting point for the local search and/or to drive the search into different regions of the search space, which can reduce the dependency of the local search on its starting point and thereby make it less dependent on restarts. Hill-climbing is one of the heuristic procedures in solving SAT problems. It needs some techniques to overcome trapping in the local minima. Most SAT local search algorithms have several static and dynamic policies to select the next variable to be flipped. They are the key component to determine the performance of SAT local search algorithms.

For static policy, the probability of a variable to be flipped depends on the current variable assignment and on the scheme to compute the *score* of a variable. For example, it depends on the number of clauses satisfied after the flip and the number of clauses broken due to the flip. For dynamic policy, the decision can depend on the

history of the search. For instance, a Tabu element can break ties between variables with an equal score according to how recently a variable has been flipped.

2.3.4 Integer Linear Programming Method for SAT

Linear programming (LP) was the first continuous optimization problem to be investigated. Conjunctive Normal Form Satisfaction problem (CNF-SAT) can be solved by an integer linear programming (ILP) model [23]. Monfroglio constructed the SAT problem as ILP in [23]. The resulting matrix has a regular structure and is no longer problem-specified. It does not depend on the structure of the clauses, but the number of clauses and the number of variables. The structure of the integer program allows us to solve the problem by using standard linear programming techniques. Simplex algorithm is one of the methods in solving linear programming problems. However, the computational complexity of the simplex algorithm is exponential in the worst case. The standard form of linear programming is

$$\begin{aligned} \min \quad & cx \\ \text{s.t.} \quad & Ax = b, x \geq 0. \end{aligned}$$

An integer linear programming problem is

$$\begin{aligned} \min \quad & cx \\ \text{s.t.} \quad & Ax = b, x \geq 0, x \text{ integer.} \end{aligned}$$

To convert the *CNF – SAT* problem into ILP problem, Monfroglio [23, 24] suggests to add nonnegative slack or surplus variables in order to convert all inequalities to equalities, replace all unrestricted variables by differences of nonnegative variables, delete all redundant rows and take the negative value of an objective function to be maximized. However, this procedure may make the problem more difficult because the additional variables and additional constraints enlarge the size of the original *CNF – SAT* problem. The worst case is to have $[n * 2m + 2m * n * (n - 1)/2]$ for the

number of columns and $[n + 2m * n * (n - 1)/2]$ for the rows in matrix A, where n is the number of literals and m is the number of clauses in the original $CNF - SAT$ problem. On the other hand, E. de klerk [25] proposes to convert the SAT problem into an integer programming problem through elliptic representation and uses a semi-definite programming method to solve the problem.

2.3.5 Semidefinite Programming Method

Semidefinite programming method is a new solution concept in optimization. Interior point methods for semidefinite programming (SDP) have been studied recently due to their polynomial complexity and practical efficiency. Most of these methods are extensions of linear optimization algorithms [26]. The most common solution approach in integer programming is to relax the integrality constraints to linear constraints and subsequently solve the resulting *LP relaxation* [27, 28]. Unfortunately, the LP relaxation of (IP_{SAT}) is weak. It is easily checked that the trival all-zero solution is always feasible when no unit clause is present. By introducing some objective function, the solution can be steered away from the trival one. The incumbent solution may be found by rounding the solution to the LP relaxation.

There are several different ways of constructing primal-dual search directions in SDP. The usual scheme is to apply linearization in conjunction with symmetrization to the perturbed optimality conditions of the SDP problem. A boolean quadratic representation of a 3-clause can be used in converting a 3-SAT problem into a semidefinite programming problem. This representation can be studied as an integer programming problem. Consider the 3-clause $p_1 \vee p_2 \vee p_3$. All valid quadratic representations for this clause follow from [27, 25, 29] are listed in Table 2.1.

After converting the problem, we can use Lagrangian dual techniques to solve the

$$\begin{array}{rcl}
x_1x_2 + x_1x_3 - x_2 - x_3 & \leq & 0 \\
x_1x_2 + x_2x_3 - x_1 - x_3 & \leq & 0 \\
x_1x_3 + x_2x_3 - x_1 - x_2 & \leq & 0 \\
-x_1x_2 - x_1x_3 - x_2x_3 - 1 & \leq & 0 \\
-x_1x_2 + x_1 + x_2 - 1 & \leq & 0 \\
-x_1x_3 + x_1 + x_3 - 1 & \leq & 0 \\
-x_2x_3 + x_2 + x_3 - 1 & \leq & 0 \\
x_1, x_2, x_3 & \in & \{-1, 1\}.
\end{array}$$

Table 2.1: Quadratic representation for 3-CNF-SAT clause

problem. Besides, E. de Klerk proposed another transformation of the SAT problem [25]. Each clause $p_1 \vee p_2 \vee p_3$ has its *elliptic representation*:

$$(x_1 + x_2 + x_3 - 1)^2 \leq 4, x_1, x_2, x_3 \in \{-1, 1\}.$$

In general, $p_1 \vee p_2 \vee \dots \vee p_n$ has elliptic representation:

$$(x_1 + \dots + x_n - 1)^2 \leq (n - 1)^2.$$

If the elliptic relaxation is infeasible, the original problem is unsatisfiable. Newton system for dual interior point methods can efficiently solve the problem. This *elliptic semidefinite feasibility problem* is *satisfiability-equivalent* to SAT for several classes of polynomially solvable formulas included 2-SAT, pigeonhole formulae and unsatisfiable formulae from graph colouring instances where clique constraints imply unsatisfiability [29]. However, there is a gap between the relaxation and its primal problem. This *gap relaxation* is always reported as feasible for 3-SAT problems if no 2-literals clauses present. These problems are reported as satisfiable even they are infeasible.

2.4 Softwares for SAT

Many SAT solvers can be found on the internet. The solution schemes in these softwares include conventional SAT techniques, complete and incomplete searching algorithms.

2.4.1 SAT01

SAT01 solver proves its efficiency empirically on *DIMACS SAT benchmarks*. It turns out that the majority of these SAT instances are fairly easy. Unfortunately, some instances were not solved because of large memory requirements. Since SAT01 solver was designed to be a general solver for NP problems, it has no specialization for SAT.

2.4.2 *SATZ* and *SATZ213*, contributed by Chu-Min Li

SATZ and *SATZ213* are two smart solvers for SAT problems. These two solvers are developed by Chu-Min Li. *SATZ* implements the algorithm proposed by Chu-Min Li that improves the traditional DPL algorithm by considering a new formula in calculating the weights for variables and using the unit propagation as the searching technique. *SATZ213* is a modification of *SATZ*.

2.4.3 Others

We list some softwares for SAT available on Internet in this section. Details can be found in “<http://www.intellektik.informatik.tu-darmstadt.de/SATLIB/solvers.html>”.

Chapter 3

Integer Programming

In last chapter, we explained what a satisfiability problem is and how to solve such kind of problem. In this chapter, we are going to review the integer programming. There are many different ways in solving integer programming. We will introduce some solution methods in the literature.

3.1 Introduction

Many real-world problems in design, operation and management may be formulated as optimization problems in which we are seeking for some values of decision variables. The objective function takes an extreme value while satisfying all the constraints imposed on these decision variables [30]. *Integer Programming* (IP) is a branch of *mathematical programming* where its decision variables are integers [30, 31]. In general, integer programming can be a constrained one or an unconstrained one, while the constraints and the objective functions can be linear or nonlinear, [32]. The general integer programming problem can be defined as:

$$\begin{array}{ll}
\text{maximize (or minimize)} & z = f(x_1, x_2, \dots, x_n) \\
\text{subject to} & g_i(x_1, x_2, \dots, x_n) \leq b_i, \quad i \in M = 1, 2, \dots, m \\
& x_j \geq 0 \quad j \in N = 1, 2, \dots, n \\
& x_j \text{ an integer} \quad j \in I \subseteq N
\end{array}$$

If $I = N$, the problem is a *Pure Integer Programming* (PIP) problem, that means all the variables x_j are restricted to integers. Otherwise, if $I \subset N$, the decision variables consist of both integer and real variables. The problem is called a *Mixed Integer Programming* (MIP) problem. If the constraints and the objective function are both linear in an integer programming problem, the problem is called a *Linear Integer Programming* problem. If the domain of the variables is binary, i.e., the decision variables can only be assigned one of the two values, the problem is called *Binary Integer Programming* (BIP) problem.

In reality, many decision making situations can be formulated as integer programming problems. Examples include *Assignment Problem*, *0-1 Knapsack Problem*, *Cutting-Stock Problem*, *Capacitated Plant Location Problem*, *Set Covering Problem*, *Traveling Salesman Problem* (TSP), *Capital Budgeting Problem*, *Sequencing Problem*, *Scheduling Problem* and *Fixed-Charge Problem* [30, 32, 33].

3.1.1 Formulation of IPs and BIPs

Before solving the IP problems and the BIP problems, formulation should be done systematically and properly. We should well define the problem instances and the decision variables used in the model [33]. The following are some guidelines.

- (1) Define the necessary decision variables used in the model.
- (2) Define the domain of the decision variables.
- (3) Define the objective function as a function of the decision variables.
- (4) Define a set of constraints imposed on the decision variables.

3.1.2 Binary Search Tree

The enumeration tree of a BIP problem can be represented as a binary tree. A binary tree consists of external (leaf) nodes and internal (non-leaf) nodes. Every internal node of a full binary tree has exactly two children. A binary search tree is a data structure of retrieving objects associated with keys. It corresponds to a full binary tree with one key stored at every internal node, and none at external nodes [34].

3.2 Methods in Solving IP problem

Integer programming solution techniques can be generally classified into two types: the search methods and the cutting methods [32]. The first type is motivated by the fact that the feasible solution points of most integer programming problems are finite (e.g., a subset of $\{0, 1\}^n$). We seek for the solution by enumerating “all” these points. This type of solution techniques includes implicit enumeration techniques and branch-and-bound techniques. The implicit enumeration is suitable for the zero-one integer programming problem, and may actually be considered as a special case of the branch-and-bound methods. Clearly, the efficiency of the resulting “search” algorithm depends on the power of the techniques that are developed to discard nonpromising solution points.

Cutting methods are developed for the mixed or pure integer linear programming problem. The idea is from the fact that the solution in the simplex method must occur at an extreme point. It adds constraints, that are violated by the current noninteger solution but never by any feasible integer point, in the original problem. Successive applications of such a procedure should eventually result in a new convex solution space with its optimum extreme point properly satisfying the integrality condition.

It cuts off those infeasible parts of the continuous solution space. However, the cutting methods can only be applied to convex problems. Also, no feasible solution is obtained until the very end of the search procedure. In the following sub-sections, we will describe four methods used in solving integer programming which are *Branch-and-Bound Methods*, *Cutting-Plane Methods*, *Duality Methods* and *Heuristic Methods*.

3.2.1 Branch-and-Bound Method

The basic concept underlying the branch-and-bound technique is dividing and conquering. Since the original “large” problem is too difficult to be solved directly, it is divided into smaller and smaller subproblems until these subproblems can be conquered. The dividing (branching) is done by partitioning the entire set of feasible solutions into smaller and smaller subsets. The conquering (fathoming) is done partially by bounding how good the best solution in the subset can be, and then discarding the subset if its bound indicates that it cannot contain an optimal solution for the original problem.

Branching

When dealing with binary variables, the most straightforward way to partition the set of feasible solutions into subsets is to fix the value of one of the variables (say, x_1) at $x_1 = 0$ for one subset and at $x_1 = 1$ for the other subset.

Figure 3.1 portrays the division procedure (branching) into subproblems by a tree with branches (arcs) from the *ALL* node (corresponding to the whole problem having *ALL* feasible solutions) to the two nodes corresponding to the two subproblems. This tree, which will continue this “branch growing” iteration by iteration, is referred to as the solution tree (or enumeration tree) for the algorithm. The variable selected to

Figure 3.1: The Solution tree created by the branching for the first iteration of the BIP branch-and-bound algorithm

do a branching at any iteration by assigning its value (as with x_1 above) is called the branching variable.

One of these subproblems can be conquered (fathomed) immediately, whereas the other subproblem will need to be divided further into smaller subproblems by setting $x_2 = 0$ or $x_2 = 1$, etc.

For other IP problems where the integer variables have more than two possible values, the branching can still be done by setting the branching variable at its respective individual values, thereby creating more than two new subproblems. However, a good alternate approach is to specify a range of values (eg. $x_j \leq 2$ or $x_j > 3$) of the branching variable for each new subproblem.

Bounding

For each of these subproblems, we need to obtain a bound on how good its best feasible solution can be. The standard way of doing this is to solve a simpler relaxation of the subproblem. In most cases, a relaxation of a problem is obtained by deleting (“relaxing”) one set of constraints that have made the problem difficult to solve. For IP problems, the most troublesome constraints are the ones that require the respective variables to be integer. Therefore, the most widely used relaxation is the *LP-Relaxation* that deletes integer constraints. In the next section, we would talk more about how to find out the bound by using *LP-Relaxation*.

Fathoming

A subproblem can be conquered (fathomed), and thereby dismissed from further consideration, if one of the following three tests is satisfied

- Test 1. Its bound $\leq Z^*$ where $Z^* = \max cx : x \in S_t$ and S_t is the feasible set of x .
- Test 2. Its LP-Relaxation has no feasible solution.
- Test 3. The optimal solution for its LP-Relaxation is integer.
(If this solution is better than the incumbent, it becomes the new incumbent, and Test 1 is reapplied to all unfathomed subproblems with the new larger Z^* .)

Unfortunately, the worst time complexity of branch-and-bound method is $O(2^n)$. A very large number of branches and nodes may be created before a feasible solution is found. The storage space may thus be large.

Techniques in Branch-and-Bound Method

There are two typical techniques in branch-and-bound-methods : *Best-first branch-and-bound* method and *Depth-first branch-and-bound* method.

Best-first Branch-and-Bound technique applies the branching process to the subproblem with the best bound. It terminates either when all nodes are reached or when the optimal solution has been found.

Depth-first Branch-and-Bound technique applies the branching process to a subproblem that has been generated by the last branching step. The procedure backtracks to the most recent alternatives when a solution has been found or when infeasibility has been encountered. It terminates when the optimal solution has been found or when all the search space has been reached. We tend to use this technique in solving CSP.

3.2.2 Cutting-Plane Method

Consider the integer programming problem of the following form

$$(P) \quad v(P) = \max \{cx \mid Ax = b, x \geq 0, x \in Z^n\}$$

where Z^n is the set of all integer points in R^n .

If an optimal solution to the linear programming relaxation, i.e., the solution to the problem (\bar{P})

$$(\bar{P}) \quad v(\bar{P}) = v(\bar{P}_0) = \max \{cx \mid Ax = b, x \geq 0\},$$

is not integer, then *cutting-plane methods* can be applied. The idea of cutting plane method consists in adding a new functional constraint (cut) $\alpha x \leq \beta$ which cuts off the optimal solution to \bar{P}_0 from $v(P)$ [30]. This reduces the feasible region for the LP relaxation without eliminating any feasible solutions for the IP problem. Then, we can obtain a new linear programming problem (\bar{P}_1) from the original problem (P) . If its optimal solution is an integer, it would be the optimal solution to (P) also. Otherwise, we can add a new cut to \bar{P}_1 to obtain \bar{P}_2 and so on. Assuming the

sequence P_0, P_1, \dots is finite, there must exist an index r such that $\bar{x} \in v^*(\bar{P}_r)$ is an integer.

There are many methods for finding the cutting planes. Hillier and Lieberman [35] proposed a method for generating cutting planes for pure BIP problems. It first considers any constraint in " \leq " form with only non-negative coefficients. Then, it finds a group of variables which is called *minimum cover* of the constraint such that the constraint is violated if every variable in the group equals to 1 and all other variables equal to 0, but the constraint becomes satisfiable if the value of any one of these variables is changed from 1 to 0. The resulting cutting plane would be

$$\boxed{\text{sum of the variables in the minimum cover} \leq N - 1}$$

where N is the number of variables in the *minimum cover*. For example, we have a constraint $3x_1 + 4x_2 + 2x_3 + 5x_4 \leq 10$. The minimum covers of the constraint are (x_1, x_2, x_4) , (x_2, x_3, x_4) and (x_1, x_2, x_3, x_4) . Therefore, the cutting planes of the constraint would be $x_1 + x_2 + x_4 \leq 2$, $x_2 + x_3 + x_4 \leq 2$ and $x_1 + x_2 + x_3 + x_4 \leq 3$.

Wolsey, Walukiewicz, and Garfinkel and Nemhauser [30, 31, 33] proposed another cutting plane method for integer programming problems. The idea is to generate a *Chvátal-Gomory inequality* on the constraint associated with a chosen basic variable after finding an optimum from the linear programming relaxation. This approach was the first cutting plane method which was proposed by Gomory [36]. The problem (P) can be rewritten as

$$\begin{aligned} \max \quad & \bar{a}_{00} + \sum_{j \in NB} \bar{a}_{0j} x_j \\ \text{s.t.} \quad & xB_u + \sum_{j \in NB} \bar{a}_{uj} x_j = \bar{a}_{u0} \text{ for } u = 1, \dots, m \\ & x \geq 0 \text{ and integer} \end{aligned}$$

with $\bar{a}_{0j} \leq 0$ for $j \in NB$, $\bar{a}_{u0} \geq 0$ for $u = 1, \dots, m$ and $xB_u = 1$ for xB_u are basic variables not in NB , where NB is the set of nonbasic variables. If the basic optimal

solution x^* is not an integer, there exists some row u with $\bar{a}_{u0} \notin Z^1$. By choosing this row, the *Chvátal – Gomory* cut for row u is

$$xB_u + \sum_{j \in NB} [\bar{a}_{uj}]x_j \leq [\bar{a}_{u0}].$$

We can rewrite this inequality by eliminating xB_u , giving

$$\sum_{j \in NB} (\bar{a}_{uj} - [\bar{a}_{uj}])x_j \geq \bar{a}_{u0} - [\bar{a}_{u0}].$$

Since $0 \leq f_{uj} < 1$ and $0 < f_{u0} < 1$, this inequality cuts off x^* as $x_j^* = 0$ for all nonbasic variables $j \in NB$ in the optimal LP solution. As a result, the slack variable s is a nonnegative integer variable where

$$s = -(\bar{a}_{u0} - [\bar{a}_{u0}]) + \sum_{j \in NB} (\bar{a}_{uj} - [\bar{a}_{uj}])x_j.$$

Consider Example 8.9 in [33],

$$\begin{aligned} z = \max \quad & 4x_1 - x_2 \\ & 7x_1 - 2x_2 \leq 14 \\ & x_2 \leq 3 \\ & 2x_1 - 2x_2 \leq 3 \\ & x_1, x_2 \geq 0 \text{ and integer} \end{aligned}$$

By adding integer slack variables x_3, x_4, x_5 , we can obtain the solution of the above problem by solving this LP problem,

$$\begin{aligned} z = \max \quad & 59/7 - 4/7x_3 - 1/7x_4 \\ & x_1 + 1/7x_3 + 2/7x_4 = 20/7 \\ & x_2 + x_4 = 3 \\ & -2/7x_3 + 10/7x_4 + x_5 = 23/7 \\ & x_1, x_2, x_3, x_4, x_5 \geq 0 \text{ and integer.} \end{aligned}$$

Since the optimal linear programming solution is $x = (20/7, 3, 0, 0, 23/7) \notin Z_+^5$, we get the cut

$$1/7x_3 + 2/7x_4 \geq 6/7 \text{ or } s = -6/7 + 1/7x_3 + 2/7x_4$$

with $s, x_3, x_4 \geq 0$ and integer. Then, we add this constraint to the original constraint set and get the solution $x = (2, 1/2, 1, 5/2, 0)$. Then, we generate the cut again for x_2 , i.e. $1/2x_5 \geq 1/2$ or $t = -1/2 + 1/2x_5$. As a result, we find an integer solution $x = (2, 1)$.

3.2.3 Duality in Integer Programming

Consider the linear programming problem,

$$\begin{aligned} \max \quad & z = cx \\ \text{s.t.} \quad & Ax \leq b \\ & x \geq 0 \end{aligned}$$

which is called the *primal problem*. There is a related LP,

$$\begin{aligned} \min \quad & v_0 = vb \\ & vA \geq c \\ & v \geq 0 \end{aligned}$$

called the *dual problem* where v is an m -dimensional row vector [31, 32]. The dual problem is derived from its primal by using the following conditions:

1. The primal objective is maximization and the dual objective is minimization.
2. The number of variables in the dual is equal to the number of constraints in the primal.
3. The number of constraints in the dual is equal to the number of variables in the primal.
4. The coefficients in the objective function of the primal form the right-hand side of the dual.
5. The right-hand side of the primal forms the coefficient of the objective of the dual.
6. All variables are nonnegative in both problems.

Obviously, the dual of the dual is the primal itself, so that either problem may be called the primal or the dual. Note that $x_0^c = v_0^c$ where x_0^c is the optimal objective

value in the primal problem and v_0^c is the optimal objective value in the dual problem. Exactly one of the following four relationships between the primal and dual problems must hold:

1. Both the primal and dual problems have optimal solutions and $x_0^c = v_0^c$.
2. The primal is unbounded and the dual is infeasible.
3. The dual is unbounded and the primal is infeasible.
4. The primal and dual are both infeasible.

Here, we know that by solving the primal (dual), we can solve the dual (primal). For LP, we can apply the simplex method to either one. Sometimes, it is possible to start with a dual feasible solution and solve the dual using the same tableau that we use in the primal simplex method. This algorithm is called the *dual simplex* method.

The Lagrangian Duality

Lagrangian Duality is one of the Dual techniques in optimization. In [37], we know that the Lagrangian Dual of a linear integer programming problem is usually formulated as a linear programming problem. The objective value in each LP subproblem is an upper bound of its original IP subproblem. Thus, Lagrangian Relaxation is usually used as the bounding relaxation for the Branch-and-Bound method. If the solution from the Lagrangian relaxation is an integer, it may be a feasible solution of the original integer programming problem. We can stop, check its feasibility and compare its objective value with the incumbent to see whether it is an optimal solution for the problem. If the solution is not an integer, we can compare its objective value with the bound in the upper level. If it is better, we can branch further. Otherwise, we prune this branch and then backtrack to the preceding node.

An alternative approach to implement Lagrangian Duality without using linear

programming problem is a *subgradient algorithm*. A *subgradient* at u of a convex function $f : R^m \rightarrow R^1$ is a vector $\gamma(u) \in R^m$ such that $f(v) \geq f(u) + \gamma(u)^T(v - u)$ for all $v \in R^m$ [33]. For a smooth convex function f , $\gamma(u) = \nabla f(u) = (\partial f / \partial u_1, \dots, \partial f / \partial u_m)$ is the gradient of f at u . The subgradient algorithm for the Lagrangian dual can be described as follows.

1. Initialization. $u = u^0$.
2. Iteration k . Set $u = u^k$. Solve the Lagrangian problem $IP(u^k)$ with optimal solution $x(u^k)$.
 - 2.1 Set $u^{k+1} = \max\{u^k - \mu_k(d - D_x(u^k)), 0\}$ and $k \leftarrow k + 1$.
3. Step size. Set $\mu_k = \epsilon_k(\bar{w} - z(u^k)) / \sum_{i \in V} (2 - \sum_{e \in \delta(i)} x_e(u^k))^2$ where \bar{w} is the upper bound in the Lagrangian Duality and $\mu_k \rightarrow 0$ with $\sum_{i=1}^{+\infty} \mu_k = +\infty$. Go to step 2.

The difficulty of this algorithm is in choosing the step size $\{\mu_k\}_{k=1}^{\infty}$. The convergence of the series $\{\mu_k\}$ may be too slow. This may affect the solution process. Also, a duality gap may exist in Lagrangian relaxation because the subgradient algorithm is often terminated before the optimal value is obtained.

3.2.4 Heuristic Algorithm

Many combinatorial problems are very difficult to be formulated as an IP or MIP when the instance is large. Even if it can be formulated as an IP or MIP, it is still difficult or impossible to find feasible solutions by using a branch-and-bound method due to its large size. Sometimes, it is easy to find feasible solutions by inspection or knowing some problem structures. A general-purpose MIP approach without using specific problem structures is usually ineffective. Hence, heuristic or approximation algorithms may be preferable because it can find a “good” feasible

solution quickly. Examples of applications of heuristic methods include time-tabling and sports scheduling problems, set covering, assignment problems and capacitated production planning problems [9].

3.3 Zero-one Optimization and Continuous Relaxation

Consider a problem of maximizing a general pseudo-Boolean function. We can formulate it as a constrained 0-1 polynomial problem. An upper bound on the maximum objective function value can be computed by constructing a Lagrangian dual. This Lagrangian dual yields an objective value equal to the roof dual value for the original 0-1 polynomial problems. Since this Lagrangian dual can be transformed to a linear programming problem, we can easily find out the roof or even the solution by checking whether a roof duality gap exists. This algorithm constitutes a basis for the bounding scheme in the branch-and-bound algorithm in this thesis.

3.3.1 Introduction

Consider the following unconstrained 0-1 polynomial programming problem

$$(P1) \quad Z_{P1} = \max_{x \in \{0,1\}^n} h(x) = \sum_{i=1}^n l_i x_i + \sum_{k=1}^n q_k \prod_{x \in S(k)} x_k.$$

Here, k is the number of nonlinear terms and for each $k = 1, \dots, K$, $S(k) \subseteq I = \{1, 2, \dots, n\}$ is the index set of binary variables whose product with a nonzero constant q_k defines the k th term.

From the paper, *Roof duality for polynomial 0-1 optimization* [5, 38], we can introduce complemented variables \bar{x} into $h(x)$ where $\bar{x}_i = 1 - x_i$, $\forall i = 1, 2, \dots, n$.

By replacing a variable by its complement in the negative term of degree 2 or more, (P1) can be reformulated such that all terms of degree 2 or more have nonnegative coefficients, each term contains at most one complemented variable, and no term contains the same variable in both the complemented and uncomplemented forms. Without loss of generality, (P1) can be rewritten as

$$(P2) \quad Z_{P2} = \max_{x \in 0,1^n, \bar{x} \in 0,1^{|I_c|}} f(x, \bar{x}) = \sum_{i=1}^n l_i x_i + \sum_{k \in P} d_k \prod_{i \in Q(k)} x_i + \sum_{k \in N} c_k \bar{x}_{T(k)} \prod_{i \in R(k)} x_i$$

where P represents the index set of all nonlinear terms which do not contain a complemented variable, N represents the index set of all nonlinear terms which contain a complemented variable, $Q(k) \subseteq I \forall k \in P$, and $R(k) \subseteq I$ with $T(k) \notin R(k) \forall k \in N$. For each term $k \in N$, $T(k)$ is the index of the associated complemented variable. Also, we define the set I_C as the index set of all variables x whose complement appears in (P2) and I_N as the index set of all variables x whose complement does not appear in (P2). Notice that $I_C \cup I_N = I$.

3.3.2 The Roof Dual expressed in terms of Lagrangian Relaxation

From [5], we can find a linear function $p(x)$ as a roof for problem (P2) iff

$$p(x) = \sum_{i=1}^n l_i x_i + \sum_{k \in N} \{v_k(1 - x_{T(k)}) + \sum_{i \in R(k)} u_{ik} x_i\} + \sum_{k \in P} \{\sum_{i \in Q(k)} \lambda_k x_i\}$$

where $v_k \in N$, $u_{ik} \forall (i, k) \exists i \in R(k)$ and $k \in N$, and $\lambda_{ik} \forall (i, k) \exists i \in Q(k)$ and $k \in P$ are scalars satisfying $(v, u, l) \geq 0$ with $v_k + \sum_{i \in R(k)} u_{ik} = c_k \forall k \in N$ and $\sum_{i \in Q(k)} \lambda_{ik} = d_k \forall k \in P$.

Clearly, any roof $p(x)$ is an upper bounding linear function of $f(x, \bar{x})$ since for all x binary,

$$\begin{aligned} \sum_{i \in Q(k)} \lambda_{ik} x_i &\geq \prod_{i \in Q(k)} x_i, \quad \forall k \in P \\ v_k \{1 - x_{T(k)} + \sum_{i \in R(k)} u_{ik} x_i\} &\geq c_k \bar{x}_{T(k)} \sum_{i \in R(k)} x_i \quad \forall k \in N \end{aligned}$$

Let R represent the set of all roofs, the roof dual is defined as

$$W(R) = \min_{p(x) \in R} \max_{x \in (0,1)^n} p(x),$$

and this value can be computed by solving the linear programming problem

$$\begin{aligned} \text{(LP)} \quad Z_{LP} \max \quad & \sum_{i=1}^n l_i x_i + \sum_{k \in P} d_k t_k + \sum_{k \in N} c_k w_k, \\ \text{s.t.} \quad & t_k \leq x_i \quad \forall (i, k) \exists i \in Q(k) \text{ and } k \in P, \\ & w_k \leq 1 - x_{T(k)} \quad \forall k \in N, \\ & 0 \leq x_i \leq 1 \quad \forall i \in I, \\ & t_k \geq 0 \quad \forall k \in P, \\ & w_k \geq 0 \quad \forall k \in N. \end{aligned}$$

where $t_k = \prod_{i \in Q(k)} x_i \quad \forall k \in P$ and $w_k = \bar{x}_{T(k)} \prod_{i \in R(k)} x_i \quad \forall k \in N$.

The set of roofs is complete in the sense that $f(x) = \min_{p(x) \in R} p(x)$ for all x binary.

The value $W(R)$ is an upper bound on Z_{P1} and the *roof duality gap* is defined as

$$W(R) - Z_{P1} = \min_{p(x) \in R} \{ \max_{x \in (0,1)^n} p(x) \} - \max_{x \in (0,1)^n} \{ \min_{p(x) \in R} p(x) \}.$$

3.3.3 Determining the Existence of a Duality Gap

In order to determine the existence of a duality gap between (P1) and its Lagrangian relaxation, we can convert (P1) into the following form by adding some redundant constraints,

$$\text{(P4)} \quad Z_{P4} = \max_{x \in (0,1)^n, \bar{x} \in (0,1)^{|J_c|}} f(x, \bar{x}) = \sum_{i \in I} l_i x_i + \sum_{k \in P} d_k \prod_{i \in Q(k)} x_i + \sum_{k \in N} c_k \bar{x}_{T(k)} \prod_{i \in R(k)} x_i$$

$$\begin{aligned}
\text{s.t. } & x_i + \bar{x}_i = 1 && \forall i \in I_c, \\
& \prod_{i \in Q(k)} x_i \leq x_i && \forall (i, k) \exists i \in Q(k) \text{ and } k \in P, \\
& \bar{x}_{T(k)} \prod_{i \in R(k)} x_i \leq \bar{x}_{T(k)} && \forall k \in N, \\
& \bar{x}_{T(k)} \prod_{i \in Q(k)} x_i \leq x_i && \forall (i, k) \exists i \in R(k) \text{ and } k \in N, \\
& x_i \geq 0 && \forall i \in I, \\
& \bar{x}_i \leq 1 && \forall i \in I_N, \\
& \bar{x}_i \geq 0 && \forall i \in I_C.
\end{aligned}$$

The continuous relaxation of (P4), (CP4), is obtained by treating all product terms as continuous variables and eliminating binary restrictions for the x and \bar{x} by $t_k = \prod_{i \in Q(k)} x_i \forall k \in P$ and $w_k = \bar{x}_{T(k)} \prod_{i \in R(k)} x_i \forall k \in N$,

$$\begin{aligned}
(\text{CP4}) \quad & Z_{\text{CP4}} = \max \sum_{i \in I} l_i x_i + \sum_{k \in P} d_k t_k + \sum_{k \in N} c_k w_k \\
\text{s.t. } & x_i + \bar{x}_i = 1 \quad \forall i \in I_C && (24) \\
& t_k \leq x_i \quad \forall (i, k) \exists i \in Q(k) \text{ and } k \in P && (25) \\
& w_k \leq \bar{x}_{T(k)} \quad \forall k \in N && (26) \\
& w_k \leq x_i \quad \forall (i, k) \exists i \in R(k) \text{ and } k \in N && (27) \\
& x_i \geq 0 \quad \forall i \in I && (28) \\
& x_i \leq 1 \quad \forall i \in I_N && (29) \\
& \bar{x}_i \geq 0 \quad \forall i \in I_C && (30)
\end{aligned}$$

From [5], we know that if there is no duality gap exists between (P4) and (CP4), (P4) and (CP4) would be consistent by considering a 0-1 quadratic posiform $p(x, \bar{x})$ where

$$\begin{aligned}
p(x, \bar{x}) = & \sum_{i \in I \beta_i \neq 0} x_i + \sum_{i \in I_N \gamma_i \neq 0} \bar{x}_i + \sum_{i \in I_C \gamma_i \neq 0} \bar{x}_i + \\
& \sum_{k \in P} \sum_{i \in Q(k) \lambda_{ik} \neq 0} \sum_{j \in Q(k) j \neq i} x_i \bar{x}_j + \sum_{k \in N v_k \neq 0} \sum_{i \in R(k)} \bar{x}_{T(k)} \bar{x}_i + \\
& \sum_{k \in N} \sum_{i \in R(k) u_{ik} \neq 0} (x_i x_{T(k)} + \sum_{j \in R(k) j \neq i} x_i \bar{x}_j).
\end{aligned}$$

However, the value of this $p(x, \bar{x})$ is very difficult to be solved. Luckily, we found out that $p(x, \bar{x})$ is consistent ONLY if all the variables are integer, i.e. $x_i = 0$ or 1. So, if the solution from CP4 is an integer solution, P4 and CP4 would be consistent. We can prove by considering the example in [5].

Consider the unconstrained 0-1 cubic programming with 4 variables

$$\max_{x \text{ binary}} h(x) = -x_3 + x_1 x_3 - x_1 x_4 + x_2 x_3 + x_3 x_4 - x_1 x_2 x_3 + x_1 x_2 x_4 - x_2 x_3 x_4$$

by substituting $x_i = 1 - \bar{x}_i$ for the smallest indexed variable in each of the negative

nonlinear term x_1x_4 , $x_1x_2x_3$ and $x_2x_3x_4$, this problem can be rewritten as

$$\max_{x, \bar{x} \text{ binary}} f(x, \bar{x}) = -x_3 - x_4 + x_1x_3 + \bar{x}_1x_4 + \bar{x}_1x_2x_3 + x_1x_2x_4 + \bar{x}_2x_3x_4$$

By using *CPLEX*¹, the solution is $(x_1 = x_2 = x_3 = x_4 = 0.5)$. The 0-1 posiform is

$$p(x, \bar{x}) = x_1\bar{x}_2 + x_1\bar{x}_3 + x_1x_4 + x_1\bar{x}_4 + \bar{x}_1x_4 + \bar{x}_1\bar{x}_2 + \bar{x}_1\bar{x}_3 + \bar{x}_1\bar{x}_4 + x_2x_3 + \bar{x}_2x_4 + x_3\bar{x}_4$$

Obviously, $p(x, \bar{x})$ is inconsistent and so a duality gap exists.

If we change the coefficients of 1 and -1 on the terms x_3x_4 and $x_2x_3x_4$ to 4 and -4 in the original function $h(x)$, the problem becomes

$$\max_{x \text{ binary}} h(x) = -x_3 + x_1x_3 - x_1x_4 + x_2x_3 + 4x_3x_4 - x_1x_2x_3 + x_1x_2x_4 - 4x_2x_3x_4 \text{ and}$$

$$\max_{x, \bar{x} \text{ binary}} f(x, \bar{x}) = -x_3 - x_4 + x_1x_3 + \bar{x}_1x_4 + \bar{x}_1x_2x_3 + x_1x_2x_4 + 4\bar{x}_2x_3x_4$$

From *CPLEX*, we can find out the solution for the problem which is $(x_1 = 1, x_2 = 0, x_3 = 1, x_4 = 1)$ and $(x_1 = 0, x_2 = 0, x_3 = 1, x_4 = 1)$. The 0-1 posiform

$$p(x, \bar{x}) = x_1x_2 + \bar{x}_1x_2 + x_1\bar{x}_3 + \bar{x}_1\bar{x}_4 + x_2x_3 + x_2\bar{x}_3 + x_2x_4 + x_2\bar{x}_4 + \bar{x}_2\bar{x}_3 + \bar{x}_2\bar{x}_4 + x_3\bar{x}_4 + \bar{x}_3x_4$$

is consistent with the above solutions. From these examples, we find that only integer solution would give $p(x, \bar{x})$ equal to 1. Thus, we can prove that the 0-1 posiform $p(x, \bar{x})$ can only be consistent if the solution is an integer solution.

3.4 Software for solving Integer Programs

There are many softwares for integer programming problem. MINTO is a software system that solves mixed-integer linear programs by a branch-and-bound algorithm with linear programming relaxations. It also provides automatic constraint classification, preprocessing, primal heuristics and constraint generation. Users can enrich the basic algorithm by providing a variety of specialized application routines that can customize MINTO to achieve maximum efficiency for a problem class.

¹*CPLEX* is a commercial LP solver that can be written in C language. Please refer to section 6.1.1 for more details.

The heart of MINTO is a linear programming based branch-and-bound algorithm. It can be implemented on top of any LP-solver, like *CPLEX* that provides capabilities to solve and modify linear programs and interpret their solutions. Details can be found in <http://akula.isye.gatech.edu/mwps/projects/minto.html>.

To be as effective and efficient as possible when used as a general purpose mixed-integer optimizer, MINTO attempts to:

- improve the formulation by preprocessing and probing;
- construct feasible solutions;
- generate strong and valid inequalities;
- perform variable fixing based on reduced prices;
- control the size of the linear programs by managing active constraints.

Chapter 4

Integer Programming Formulation for SAT Problem

To solve the 3-CNF SAT problem, we can convert a satisfiability problem into an integer constrained maximization problem formulation. We can then use a branch-and-bound algorithm to find out if a feasible solution exist for the original problem. By considering the Venn Diagram for 3 independent parties, we can set up some axioms for converting the CNF clauses into IP constraints. In this chapter, we would show how to set up these axioms and convert the problem into a singly-constrained 0-1 polynomial problem.

4.1 From 3-CNF SAT Clauses to Zero-One IP Constraints

There are many methods to convert the 3-SAT clauses into IP constraints. Etienne de Klerk [25] proposed to use *Semidefinite Programming* (SDP) approach to solve the

$(x_1 \vee x_2 \vee x_3)$	$= x_1 + x_2 + x_3 - x_1x_2 - x_1x_3 - x_2x_3 + x_1x_2x_3$
$(x_1 \vee x_2 \vee \bar{x}_3)$	$= 1 - x_3 + x_1x_3 + x_2x_3 - x_1x_2x_3$
$(x_1 \vee \bar{x}_2 \vee \bar{x}_3)$	$= 1 - x_2x_3 + x_1x_2x_3$
$(\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3)$	$= 1 - x_1x_2x_3$

Table 4.1: Axioms for transforming the 3-SAT clause into Integer Programming format

SAT problem. As we stated in chapter 2, there are 7 forms of valid *elliptic representations* for 3-literal clauses [25]. Any clause can be transformed to a combination of these *elliptic representations*. The domain of the variables would be -1 or 1 instead of 0 or 1. If these *elliptic representations* are infeasible, the primal 3-CNF formula will be unsatisfiable. However, the *elliptic* semidefinite feasibility problem is “satisfiability-equivalent” to 2-SAT. It is always feasible for “pure 3-SAT” problem. It has to make some adjustment so that it can detect the unsatisfiability of 3-SAT problem.

Actually, we have an easier way to convert the CNF clauses into IP constraints. Consider the Venn diagram with 3 independent parties in Figure 4.1. The shared area of the union of three parties is the sum of these 3 parties, minus the intersection of 2 out of these 3 parties, and plus the intersection of these 3 parties. Thus, we can have

$$\begin{aligned} (x_1 \vee x_2 \vee x_3) &= x_1 + x_2 + x_3 - (x_1 \wedge x_2) - (x_1 \wedge x_3) - (x_2 \wedge x_3) + (x_1 \wedge x_2 \wedge x_3) \\ &= x_1 + x_2 + x_3 - x_1x_2 - x_1x_3 - x_2x_3 + x_1x_2x_3 \end{aligned}$$

In addition, we can rewrite \bar{x}_i as $(1 - x_i)$ and form the axioms listed in Table 4.1.

Since each literal can only take the true value 0 or 1, each clause should return the value 1 if it is consistent. Therefore, we can transform the CNF clause into an IP constraint as in Table 4.2.

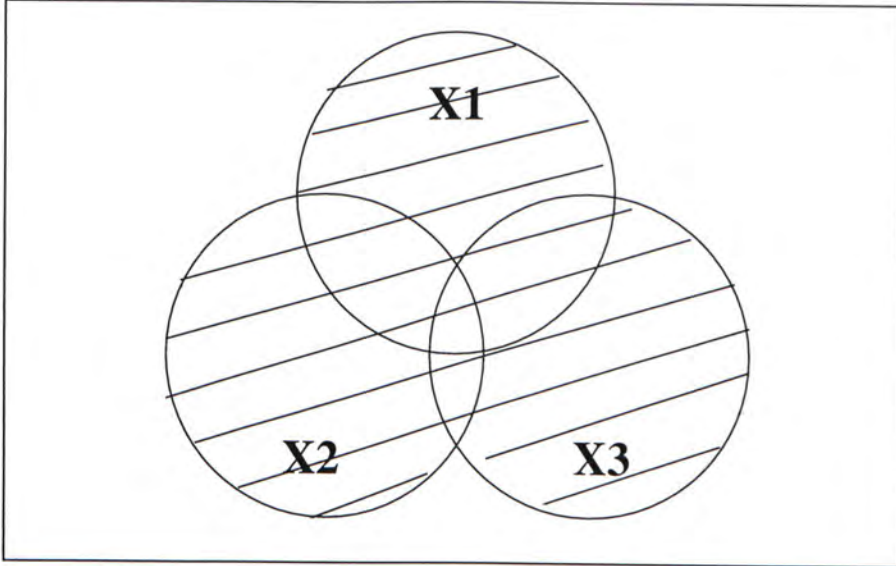

Figure 4.1: Venn Diagram for 3 independent parties x_1 , x_2 and x_3

$(x_1 \vee x_2 \vee x_3) \Rightarrow x_1 + x_2 + x_3 - x_1x_2 - x_1x_3 - x_2x_3 + x_1x_2x_3 \geq 1$
$(x_1 \vee x_2 \vee \bar{x}_3) \Rightarrow 1 - x_3 + x_1x_3 + x_2x_3 - x_1x_2x_3 \geq 1$
$(x_1 \vee \bar{x}_2 \vee \bar{x}_3) \Rightarrow 1 - x_2x_3 + x_1x_2x_3 \geq 1$
$(\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3) \Rightarrow 1 - x_1x_2x_3 \geq 1$

Table 4.2: IP constraint for converting 3-SAT clause

For example,

$$(x_1 \vee x_2 \vee x_3) \wedge (x_1 \vee \bar{x}_2 \vee \bar{x}_4) \Rightarrow \begin{aligned} x_1 + x_2 + x_3 - x_1x_2 - x_1x_3 - x_2x_3 + x_1x_2x_3 &\geq 1 \wedge \\ 1 - x_2x_4 + x_1x_2x_4 &\geq 1 \end{aligned}$$

Now, we can convert m ($= 4.25 * n$) clauses into m IP constraints, where n is the number of variables in the original CNF problem.

4.2 From m -Constrained IP Problem to Singly-Constrained IP Problem

At this stage, we have total m IP constraints where each constraint is a polynomial representation with its value larger than or equal to 1. That is,

$$g_1 \geq 1, g_2 \geq 1, \dots, g_m \geq 1$$

where $m = 4.25 * n$ and n is the number of variables in the original problem.

In this thesis, the domain of variables is binary (0 or 1). There is no doubt that each IP constraint can only return the value of 0 or 1, i.e., $g_i \in \{0, 1\}$. If the problem is feasible, such that all the constraints are satisfied, the sum of these constraints should be equal to m , $\sum_{i=1}^m g_i(x) = m$. If the sum of these constraints is less than m ($\sum_{i=1}^m g_i(x) < m$), the original problem must be infeasible. Thus, we can combine these m IP constraints together into an unconstrained zero-one polynomial maximization problem, that is

$$\max \sum_{i=1}^m g_i(x).$$

If the original problem is feasible, the optimal objective value should return a value of m . If the value of the optimal objective value is smaller than m , that means

the original problem is infeasible. Therefore, the original problem and the singly-constrained zero-one polynomial problem are equivalent.

4.2.1 Example

In order to implement the transformation, we generate a 5-variables problem randomly. There are 22 (4.25*5) clauses where each clause contains exactly 3 literals.

The problem is listed as below:

$$x_4 \vee \bar{x}_2 \vee x_5$$

$$\bar{x}_3 \vee x_5 \vee \bar{x}_2$$

$$\bar{x}_4 \vee \bar{x}_1 \vee \bar{x}_5$$

$$x_2 \vee \bar{x}_3 \vee \bar{x}_4$$

$$\bar{x}_5 \vee x_4 \vee \bar{x}_1$$

$$x_2 \vee \bar{x}_3 \vee x_1$$

$$\bar{x}_5 \vee \bar{x}_2 \vee \bar{x}_3$$

$$\bar{x}_4 \vee x_1 \vee x_3$$

$$x_5 \vee \bar{x}_1 \vee \bar{x}_4$$

$$\bar{x}_3 \vee \bar{x}_2 \vee \bar{x}_4$$

$$\bar{x}_1 \vee x_3 \vee x_5$$

$$x_5 \vee \bar{x}_3 \vee \bar{x}_4$$

$$x_1 \vee \bar{x}_2 \vee x_4$$

$$\bar{x}_5 \vee x_4 \vee \bar{x}_2$$

$$x_2 \vee x_4 \vee \bar{x}_5$$

$$\bar{x}_5 \vee x_1 \vee \bar{x}_3$$

$$x_3 \vee x_2 \vee \bar{x}_1$$

$$\bar{x}_1 \vee x_2 \vee \bar{x}_4$$

$$x_5 \vee x_1 \vee x_2$$

$$\bar{x}_3 \vee \bar{x}_2 \vee x_5$$

$$\bar{x}_5 \vee \bar{x}_3 \vee \bar{x}_1$$

$$x_4 \vee \bar{x}_2 \vee x_3$$

Then, we convert these 3-CNF-SAT clauses into IP constraints. The problem can be formulated as

$$x_4 \vee \bar{x}_2 \vee x_5 \Rightarrow 1 - x_2 + x_2x_4 + x_2x_5 - x_2x_4x_5 \geq 1$$

$$\bar{x}_3 \vee x_5 \vee \bar{x}_2 \Rightarrow 1 - x_2x_3 + x_2x_3x_5 \geq 1$$

$$\bar{x}_4 \vee \bar{x}_1 \vee \bar{x}_5 \Rightarrow 1 - x_1x_4x_5 \geq 1$$

$$x_2 \vee \bar{x}_3 \vee \bar{x}_4 \Rightarrow 1 - x_3x_4 + x_2x_3x_4 \geq 1$$

$$\bar{x}_5 \vee x_4 \vee \bar{x}_1 \Rightarrow 1 - x_1x_5 + x_1x_4x_5 \geq 1$$

$$x_2 \vee \bar{x}_3 \vee x_1 \Rightarrow 1 - x_3 + x_1x_3 + x_2x_3 - x_1x_2x_3 \geq 1$$

$$\bar{x}_5 \vee \bar{x}_2 \vee \bar{x}_3 \Rightarrow 1 - x_2x_3x_5 \geq 1$$

$$\bar{x}_4 \vee x_1 \vee x_3 \Rightarrow 1 - x_4 + x_1x_4 + x_3x_4 - x_1x_3x_4 \geq 1$$

$$x_5 \vee \bar{x}_1 \vee \bar{x}_4 \Rightarrow 1 - x_1x_4 + x_1x_4x_5 \geq 1$$

$$\bar{x}_3 \vee \bar{x}_2 \vee \bar{x}_4 \Rightarrow 1 - x_2x_3x_4 \geq 1$$

$$\bar{x}_1 \vee x_3 \vee x_5 \Rightarrow 1 - x_1 + x_1x_3 + x_1x_5 - x_1x_3x_5 \geq 1$$

$$x_5 \vee \bar{x}_3 \vee \bar{x}_4 \Rightarrow 1 - x_3x_4 + x_3x_4x_5 \geq 1$$

$$x_1 \vee \bar{x}_2 \vee x_4 \Rightarrow 1 - x_2 + x_1x_2 + x_2x_4 - x_1x_2x_4 \geq 1$$

$$\bar{x}_5 \vee x_4 \vee \bar{x}_2 \Rightarrow 1 - x_2x_5 + x_2x_4x_5 \geq 1$$

$$x_2 \vee x_4 \vee \bar{x}_5 \Rightarrow 1 - x_5 + x_2x_5 + x_4x_5 - x_2x_4x_5 \geq 1$$

$$\bar{x}_5 \vee x_1 \vee \bar{x}_3 \Rightarrow 1 - x_3x_5 + x_1x_3x_5 \geq 1$$

$$x_3 \vee x_2 \vee \bar{x}_1 \Rightarrow 1 - x_1 + x_1x_2 + x_1x_3 - x_1x_2x_3 \geq 1$$

$$\bar{x}_1 \vee x_2 \vee \bar{x}_4 \Rightarrow 1 - x_1x_4 + x_1x_2x_4 \geq 1$$

$$x_5 \vee x_1 \vee x_2 \Rightarrow x_1 + x_2 + x_5 - x_1x_2 - x_1x_5 - x_2x_5 + x_1x_2x_5 \geq 1$$

$$\bar{x}_3 \vee \bar{x}_2 \vee x_5 \Rightarrow 1 - x_2x_3 + x_2x_3x_5 \geq 1$$

$$\bar{x}_5 \vee \bar{x}_3 \vee \bar{x}_1 \Rightarrow 1 - x_1x_3x_5 \geq 1$$

$$x_4 \vee \bar{x}_2 \vee x_3 \Rightarrow 1 - x_2 + x_2x_3 + x_2x_4 - x_2x_3x_4 \geq 1$$

Finally, we combine all these constraints together to form a singly-constrained polynomial problem as

$$\begin{aligned} & -x_1 - 2x_2 - x_3 - x_4 + x_1x_2 + 3x_1x_3 - x_1x_4 - x_1x_5 + 3x_2x_4 - x_3x_4 - x_3x_5 + x_4x_5 - \\ & 2x_1x_2x_3 - x_1x_3x_4 - x_2x_3x_4 + x_1x_2x_5 - x_1x_3x_5 + x_1x_4x_5 + x_2x_3x_5 - x_2x_4x_5 + x_3x_4x_5 \geq 1 \end{aligned}$$

Now, we can use branch-and-bound algorithm to solve the resulting singly-constrained zero-one polynomial problem, then check the satisfiability of the original problem. Branch-and-bound algorithm is a simple method in solving the IP problem. In the next chapter, we will show how to choose the branch rule and the bound rule for our IP problem. Also, an example is used to show the details of the algorithm.

Chapter 5

A Basic Branch-and-Bound Algorithm for the Zero-One Polynomial Maximization Problem

After converting the 3-CNF-SAT problem into an IP problem, we would use a branch-and-bound method to find out whether the problem is feasible. To solve an integer programming problem, there are many methods in the literature, such as Branch-and-Bound methods, Cutting Planes, etc. In this chapter, we will express the reason for choosing Branch-and-Bound method as our algorithm rather than others. Also, we will discuss our branch and bound rules in the coming sections.

5.1 Reason for choosing Branch-and-Bound Method

There are many methods in solving an integer programming problem. Branch-and-bound and cutting planes are two typical solution schemes in the literature. Branch-and-bound method is quite popular. However, the time complexity is $O(2^n)$ in the

worst case where n is the number of variables. For a large problem, cutting planes may do better. In each iteration, it reduces the feasible region by cutting down the region that does not contain feasible solutions. However, we can only apply cutting planes method to those constraints which are convex. In this thesis, the resulting zero-one polynomial maximization problem does not possess a convexity. Branch-and-bound method seems to be more suitable as being the skeleton of our searching algorithm. For a branch-and-bound algorithm, we have to set up a branch rule and a bound rule for the search procedure. For the branch rule, we have to identify a branching variable at each node by considering the weight of each variable in the constraint. In each iteration, we have to define the upper bound and lower bound for the subproblem. In the following sections, we will discuss how to choose our branch rule and bound rule.

5.2 Searching Algorithm

The searching algorithm in this section would begin by checking whether the problem is solvable. We would first check the feasibility of the problem. If the right hand side of the constraint, b , is non-positive, we could set all the variables at zero and return the solution. If the sum of all the coefficients of the constraint is larger than or equal to the right hand side (RHS), then we set all the variables at one and return the solution. If it is neither the above two cases, we have to continue an iteration process. Thus, we have to execute the following procedure.

First, we calculate the number of *occurrence* of each variable according to its *positive terms* and its *negative terms* in the objective. If the number of occurrence of a variable with positive terms is 0, the existence of that variable would lower the LHS

value (sum of the coefficients of all the variable terms) of the objective. Thus, we set that variable to be 0. On the other hand, if the number of occurrence of a variable with negative terms is 0, then we set that variable to be 1 because the existence of that variable would raise up the *LHS* value.

If it is not the above cases, we need to find out the branching variable by a branch rule. We substitute this branching variable by a suitable value (0 or 1) to the constraint and simplify it. We will discuss more about this in the next section. Next, after updating the constraint, we have to check the *LHS* value and the *RHS* value of the subproblem. If the right hand side of the constraint, b , is non-positive, we would set the unassigned variables at zero, stop and return the solution. If the sum of the coefficients of all the variable terms of the constraint is larger than or equal to the right hand side, we set all the unassigned variables at one, stop and return the solution. Then, we check the satisfiability of the original problem by substituting the solution into the objective function. Here, we can find out the upper and lower bound of our subproblem. The values of the upper and lower bound are the sum of coefficients of the positive and negative terms, respectively. The upper and lower bound at each iteration should be within the boundaries of its predecessor. In section 5.2.2, we will explain the details of how the bound works. At this stage, if a dead end is reached, we backtrack to the latest node. If a feasible solution is found, we will stop and report the feasibility of the problem. Otherwise, we will branch further by repeating the above procedures until a dead end is reached or all nodes are checked.

5.2.1 Branch Rule

For constrained satisfiability problem, the order of labeling and the domain size of the variables are essential in labeling the variables. Domain of a variable is the range

that represents the values of the variable. Labeling is a kind of elimination method which uses a backtracking search to find a solution to the constraints. The order of labeling is the order of variables being labelled in the binary search tree. A good variable ordering can shorten the time of searching.

In “Programming with Constraints: An Introduction” [10], Marriott and Stuckey proposed to separate the variable list into 2 halves and then form in an order. Besides, we can choose the branching variables according to the domain size of the variables. However, this may not be applicable in this thesis because the domain of the variables is binary. It may be meaningless if we sort the variables depending on their domains. According to this, we may need to think of a suitable branching rule for our thesis.

Let us look at the solution tree shown in Figure 5.1. In each iteration, we have to find a branching variable to explore. If no variable has a zero positive occurrence or a zero negative occurrence in the reduced objective function of a subproblem, we need to find out the branching variable that has the largest occurrence of positive terms. If more than one variable have the same number of the largest occurrence, we choose one involved in a term with the largest absolute coefficient. We set the branching variable at 1.

For example, we have a reduced objective $2x_1 - 4x_3 - x_1x_2 + 2x_2x_3$. The numbers of both positive and negative occurrences of these variables are 1. However, the coefficient of one term involving x_3 has the largest absolute value, 4. So, we set x_3 as our branching variable and set $x_3 = 1$.

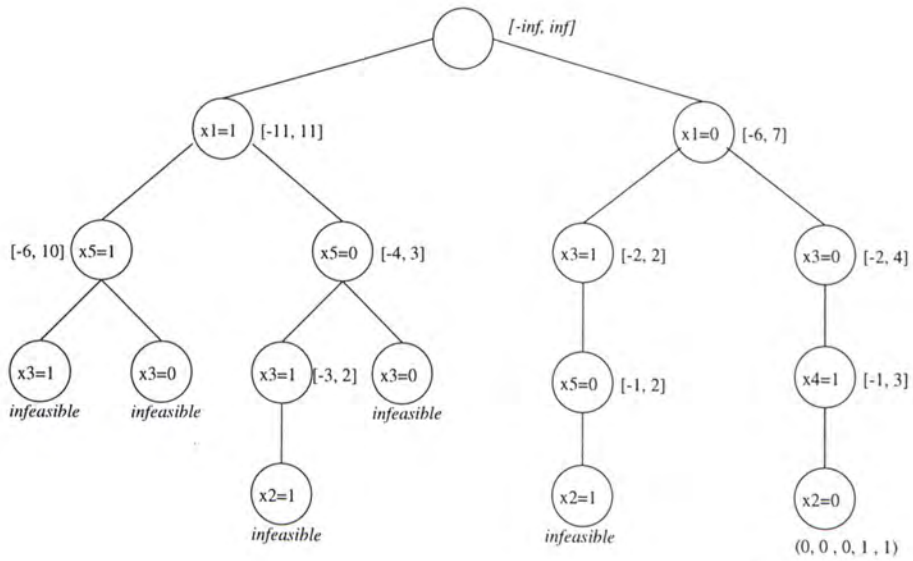

Figure 5.1: The solution tree for checking the satisfiability of a 5-variables problem.

5.2.2 Bounding Rule

For any IP problem, we can find an upper bound and a lower bound of the subproblem. The easiest way is to set the sum of all its positive coefficients as the upper bound and the sum of the negative coefficients as its lower bound. During the iterations, the region of these bounds should become tighter and tighter.

5.2.3 Fathoming Test

The fathoming tests in our algorithm are similar to those in the conventional branch-and-bound method and are listed as follows

Test 1. The upper bound is less than the RHS.

Test 2. An integer optimal solution is found.

In the following section, we will use a simple example with 5 variables in Chapter

4 to test the performance of our algorithm. This example will also be used in the following two chapters to check the performances of the revised branch and bound rules.

5.2.4 Example

After converting the CNF problem into IP problem as in Section 4.2.1, the constraint becomes

$$-x_1 - 2x_2 - x_3 - x_4 + x_1x_2 + 3x_1x_3 - x_1x_4 - x_1x_5 + 3x_2x_4 - x_3x_4 - x_3x_5 + x_4x_5 - 2x_1x_2x_3 - x_1x_3x_4 - x_2x_3x_4 + x_1x_2x_5 - x_1x_3x_5 + x_1x_4x_5 + x_2x_3x_5 - x_2x_4x_5 + x_3x_4x_5 \geq 1$$

Since the *RHS* of the constraint is positive and the *LHS* value (adding the coefficients of all variable terms) equals to -3, we set the upper and lower bound of the problem as 12 and -15 which are the sum of all positive and negative coefficients, respectively.

Iteration 1:

(1) We set up an occurrence table as below:

	x_1	x_2	x_3	x_4	x_5
+ve	4	4	3	4	5
-ve	6	4	7	6	4

(2) Since there is no variable that contains only positive or negative occurrence, we choose x_5 to be the branching variable and set it at 1.

(3) The constraint can be reduced as

$$(I): -2x_1 - 2x_2 - 2x_3 + 2x_1x_2 + 2x_1x_3 + x_2x_3 + 2x_2x_4 - 2x_1x_2x_3 - x_1x_3x_4 - x_2x_3x_4 \geq 1$$

(4) The *RHS* of the constraint is positive and the *LHS* value equals to -3. Since the upper bound and the lower bound of the subproblem (I) are 7 and -10 respectively, we continue branching.

Searching Algorithm for CSP

Procedure:

- (1) (i) If the RHS of the constraint is non-positive, set the unassigned variable to be 0. Stop and go to (10).
- (1) (ii) If the sum of all the coefficient of the constraint is larger than the RHS, set the unassigned variable to be 1. Stop and go to (10).
- (2) Set the upper bound and lower bound of the primal problem as the sum of positive and negative coefficients of all the terms, respectively.
- (3) Calculate the number of occurrence of each variable in the constraint according to
 - (i) positive coefficient
 - (ii) negative coefficient
- (4) (i) If the number of occurrence of variable in (3)(i) is 0, then we set that variable to 0.
- (4) (ii) If the number of occurrence of variable in (3)(ii) is 0, then we set that variable to 1.
- (4) (iii) Go to (6).
- (5) *Branch Rule:*
 - (i) Choose the variable with the largest occurrence in positive term.
 - (ii) If more than one variable have the same weight, choose a variable with the largest absolute coefficient of its term.
 - (iii) Set the branching variable at 1.
- (6) Update the constraint.
- (7) (i) If the RHS of the constraint is non-positive, set the unassigned variable to be 0. Stop and go to (10).
- (7) (ii) If the sum of all the coefficient in LHS of the constraint is larger than the RHS, set the unassigned variable to be 1. Stop and go to (10).
- (8) (i) *Bound Rule*
Set the upper and lower bound of the subproblem by adding up the positive and negative coefficient of subproblem respectively.
- (8) (ii) If solution is found or all the nodes have been reached, stop and go to (10).
- (8) (iii) If dead end is reached, backtrack to the latest node.
- (9) Go back to (3).
- (10) Return the feasibility of the problem and the feasible solution if it is satisfiable.

Table 5.1: The branch-and-bound algorithm for the singly-constrained polynomial CSP.

Iteration 2:

(1) We set up an occurrence table as below:

	x_1	x_2	x_3	x_4
+ve	2	3	2	1
-ve	3	3	4	2

(2) Since there is no variable that contains only positive or negative occurrence, we choose x_2 to be the branching variable and set it at 1.

(3) The constraint can be reduced as

$$(II): -x_3 + 2x_4 - x_3x_4 - x_1x_3x_4 \geq 3$$

(4) The *RHS* of the constraint is positive and the *LHS* value equals to -1. Since the upper bound and the lower bound of the subproblem (II) are 2 and -3 respectively, we continue branching.

Iteration 3:

(1) We set up an occurrence table as below:

	x_1	x_3	x_4
+ve	0	0	1
-ve	1	3	2

(2) Since x_1 and x_3 have negative occurrence only, we set both x_1 and x_3 at 0.

(3) The constraint can be reduced as

$$(III): 2x_4 \geq 3$$

(4) The *RHS* of the constraint is positive and the *LHS* value equals to 2. Obviously, the problem is infeasible and so we backtrack at $x_2 = 0$.

Backtrack at $x_2 = 0$:

(1) The constraint can be formed as

(IV): $-2x_1 - 2x_3 + 2x_1x_3 - x_1x_3x_4 \geq 1$

(2) The *RHS* of the constraint is positive and the *LHS* value equals to -3. From here, we find that the upper bound and the lower bound of the subproblem (IV) are 2 and -5. We continue branching.

Iteration 4:

(1) We set up an occurrence table as below:

	x_1	x_3	x_4
+ve	1	1	0
-ve	2	2	1

(2) Since x_4 has the negative occurrence only, we set x_4 at 0.

(3) The constraint can be reduced as

(V): $-2x_1 - 2x_3 + 2x_1x_3 \geq 1$

(4) The *RHS* of the constraint is positive and the *LHS* value equals to -2. From here, we find that the upper bound and the lower bound of the subproblem (V) are 2 and -4. We continue branching.

Iteration 5:

(1) We set up an occurrence table as below:

	x_1	x_3
+ve	1	1
-ve	1	1

(2) Since there is no variable that contains only positive or negative occurrence, we choose x_1 to be the branching variable and set it at 1.

(3) The constraint can be reduced as

(VI): $0 \geq 3$

(4) Obviously, the problem is infeasible and so we backtrack at $x_1 = 0$.

Backtrack at $x_1 = 0$:

(1) The constraint can be formed as

$$(VII): -2x_3 \geq 1$$

(2) The *RHS* of the constraint is positive and the *LHS* value equals to -2. Obviously, the problem is infeasible and so we backtrack at $x_5 = 0$.

Backtrack at $x_5 = 0$:

(1) The constraint can be formed as

$$(VIII): -x_1 - 2x_2 - x_3 - x_4 + x_1x_2 + 3x_1x_3 - x_1x_4 + 3x_2x_4 - x_3x_4 - 2x_1x_2x_3 - x_1x_3x_4 - x_2x_3x_4 \geq 1$$

(2) Since the *RHS* of the constraint is positive and the *LHS* value equals to -4. From here, we find that the upper bound and the lower bound of the subproblem (VIII) are 7 and -11, respectively. We continue branching.

Iteration 6:

(1) We set up an occurrence table as below:

	x_1	x_2	x_3	x_4
+ve	2	2	1	1
-ve	4	3	5	5

(2) Since there is no variable that contains only positive or negative occurrence, we choose x_1 to be the branching variable and set it at 1.

(3) The constraint can be reduced as

$$(IX): -x_2 + 2x_3 - 2x_4 - 2x_2x_3 + 3x_2x_4 - 2x_3x_4 - x_2x_3x_4 \geq 2$$

(4) The *RHS* of the constraint is positive and the *LHS* value equals to -3. From here, we find that the upper bound and lower bound of the subproblem (IX) are 5 and -8,

respectively. We continue branching.

Iteration 7:

(1) We set up an occurrence table as below:

	x_2	x_3	x_4
+ve	1	1	1
-ve	3	3	3

(2) Since there is no variable that contains only positive or negative occurrence, we choose x_2 to be the branching variable and set it at 1.

(3) The constraint can be reduced as

$$(X): x_4 - 3x_3x_4 \geq 3$$

(4) The *RHS* of the constraint is positive and the *LHS* value equals to -2. From here, we find that the upper bound and lower bound of the subproblem (X) are 1 and -3, respectively. We continue branching.

Iteration 8:

(1) We set up an occurrence table as below:

	x_3	x_4
+ve	0	1
-ve	1	1

(2) Since x_3 has negative occurrence only, we set x_3 at 0.

(3) The constraint can be reduced as

$$(XI): x_4 \geq 3$$

(4) The *RHS* of the constraint is positive and the *LHS* value equals to 1. Obviously, the problem is infeasible and so we backtrack at $x_2 = 0$.

Backtrack at $x_2 = 0$:

(1) The constraint can be formed as

$$(XII): 2x_3 - 2x_4 - 2x_3x_4 \geq 2$$

(2) The *RHS* of the constraint is positive and the *LHS* value equals to -2. From here, we find that the upper bound and the lower bound of the subproblem (XII) are 2 and -4. We continue branching.

Iteration 9:

(1) We set up an occurrence table as below:

	x_3	x_4
+ve	1	0
-ve	1	2

(2) Since x_4 has the negative occurrence only, we set x_4 at 0.

(3) The constraint can be reduced as

$$(XIII): 2x_3 \geq 2$$

(4) From here, we find that the *LHS* value of the subproblem (XIII) equals to the *RHS*. We set $x_3 = 1$.

(5) Since a feasible solution is found (i.e. $x_1 = 1, x_2 = 0, x_3 = 1, x_4 = 0, x_5 = 0$), we stop and report that the problem is satisfiable.

Conclusion

From the above example, we can see that our branch-and-bound algorithm is better than the conventional backtracking method. Although the number of iterations is reduced, we still have to branch to a deeper level for checking the satisfiability, especially for those infeasible branches. In the following chapters, we will discuss revised branch and bound rules so as to improve the performance of our branch-and-bound method.

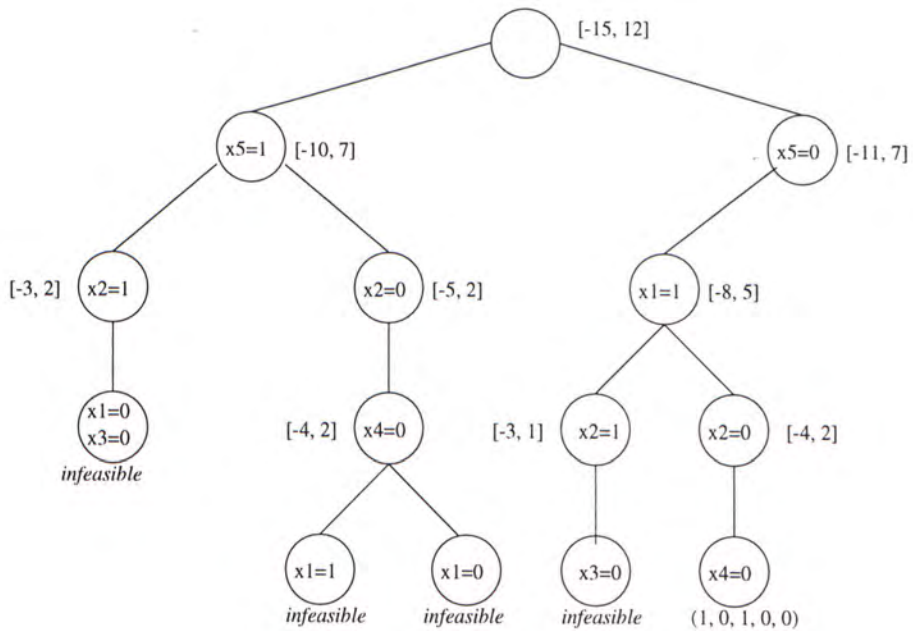

Figure 5.2: The solution tree of the problem $-x_1 - 2x_2 - x_3 - x_4 + x_1x_2 + 3x_1x_3 - x_1x_4 - x_1x_5 + 3x_2x_4 - x_3x_4 - x_3x_5 + x_4x_5 - 2x_1x_2x_3 - x_1x_3x_4 - x_2x_3x_4 + x_1x_2x_5 - x_1x_3x_5 + x_1x_4x_5 + x_2x_3x_5 - x_2x_4x_5 + x_3x_4x_5 \geq 1$ under our basic searching algorithm

Chapter 6

Revised Bound Rule for Branch-and-Bound Algorithm

In last chapter, we have discussed a basic branch-and-bound algorithm to solve our zero-one polynomial maximization problem. From the example in section 5.2.4, we find that the performance of the algorithm is not so good, that is, we have to search in a deeper level for infeasibility. In this chapter, we propose another bound rule that can produce a tighter bound for the subproblem. A linear programming problem is formed to figure out the upper bound of each subproblem and a powerful solver, *CPLEX* is used to solve the reduced linear programming problem. We will end with an example in section 5.2.4 to see the performance of using this tighter-bound rule.

6.1 Revised Bound Rule

The procedure of the revised bound rule is described as below. In Chapter 3, we describe a method in solving zero-one optimization problems through its relaxation.

Bounding Rule

- (1) Transform the subproblem into P4 and CP4 and solve the CP4 by using *CPLEX*.
- (2) If x is an integer solution, i.e. P4 and CP4 are consistent,
 - (i) if $Z_{CP4} \geq RHS_{subproblem}$, return x as the feasible solution of the original problem.
 - (ii) if $Z_{CP4} < RHS_{subproblem}$, the subproblem is infeasible and backtrack to the previous node.
- (3) If x is not an integer solution, i.e. P4 and CP4 are inconsistent,
 - (i) Z_{CP4} is the upper bound of the subproblem.
 - (ii) if $Z_{CP4} < RHS_{subproblem}$, then stop and return the subproblem as infeasible and backtrack to the previous node.
 - (iii) if $Z_{CP4} \geq RHS_{subproblem}$, we continue branching.

Table 6.1: Revised Bound Rule for the CSP

Now, we will apply a similar way to find out the upper bound or even the feasible integer solution of zero-one optimization problem. We first transform the subproblem into the form of P4 and CP4 as discussed in Chapter 3. Then, we can find out its solution by using a dual method. If x is an integer solution of the dual problem, CP4 and P4 are consistent. We can then check the satisfiability by checking whether the objective value, Z_{CP4} , is larger than or equal to the *RHS* of the subproblem. If so, we can stop and return the solution x^* , where x^* is the optimal solution of the subproblem. Thus, x^* is a feasible solution to the original problem. Otherwise, this subproblem is infeasible and we need to backtrack at the previous nodes.

If x is not an integer solution, CP4 and P4 are inconsistent. We can still find the upper bound (Z_{CP4}) of the subproblem. If Z_{CP4} is smaller than the *RHS* of the subproblem, the subproblem is infeasible and we backtrack to the latest node. Otherwise, we can continue branching. The revised bound rule is listed in Table 6.1.

6.1.1 CPLEX

In [5], it is suggested to use a Lagrangian dual method to solve the zero-one polynomial problem. Lagrangian dual method is a powerful solution scheme in integer programming problem. It reduces the primal zero-one polynomial problem into a linear programming problem which is easier to solve.

In this thesis, we use *CPLEX* as a solver for solving the linear relaxation of the subproblem. *CPLEX* is designed to solve linear programming problems using *Simplex method*. It can solve a linear programming problem by using the primal-simplex optimizer, the dual-simplex optimizer or the primal-dual barrier optimizer. If a linear program contains a substantial network, a special network optimizer can be used. If the problem includes integer variables, a branch-and-bound method must be used. If the problem is a convex quadratic programming problem, the primal-dual barrier optimizer must be used. Many practical problems can be solved faster by its *dual-simplex*.

On the other hand, *CPLEX* is callable in C or C++ language and so it can be embedded in any programme in C or C++. In this thesis, we use C language to implement the whole search procedure, including both branch and bound rules by calling *CPLEX* as a solver for CP4 formulation of the primal subproblem. In the following section, we will use the example in last chapter to test the performance of our revised bound rule.

6.2 Example

Refer to the example in section 5.2.4, the constraint is

$$-x_1 - 2x_2 - x_3 - x_4 + x_1x_2 + 3x_1x_3 - x_1x_4 - x_1x_5 + 3x_2x_4 - x_3x_4 - x_3x_5 + x_4x_5 -$$

$$2x_1x_2x_3 - x_1x_3x_4 - x_2x_3x_4 + x_1x_2x_5 - x_1x_3x_5 + x_1x_4x_5 + x_2x_3x_5 - x_2x_4x_5 + x_3x_4x_5 \geq 1$$

We do a similar procedure except that we would use the revised bound rule to find a solution and a tighter upper bound for the subproblem. Since the *RHS* of the constraint is positive and the *LHS* equals to 1, we set the upper and lower bound of the problem as 16 and -15, respectively. Before processing the search algorithm, we set up P4 and CP4 for the primal problem for checking the satisfiability of primal problem. P4: Max $-x_1 - 2x_2 - 3x_3 - 5x_4 - 3x_5 + x_1x_2 + 3x_1x_3 + \bar{x}_1x_4 + \bar{x}_1x_5 + 2\bar{x}_2x_3 + 3x_2x_4 + 3\bar{x}_3x_4 + 2\bar{x}_3x_5 + 2\bar{x}_1x_2x_3 + \bar{x}_1x_3x_4 + \bar{x}_2x_3x_4 + x_1x_2x_5 + \bar{x}_1x_3x_5 + x_1x_4x_5 + x_2x_3x_5 + \bar{x}_2x_4x_5 + x_3x_4x_5$

s.t.

$$\begin{array}{lll}
x_1 + \bar{x}_1 = 1 & x_2 + \bar{x}_2 = 1 & x_3 + \bar{x}_3 = 1 \\

x_1, x_2, x_3, x_4, x_5, \bar{x}_1, \bar{x}_2, \bar{x}_3 & \text{binary} & & & & & & & &
\end{array}$$

Let $t_1 = x_1x_2, t_2 = x_1x_3, w_3 = \bar{x}_1x_4, w_4 = \bar{x}_1x_5, w_5 = \bar{x}_2x_3, t_6 = x_2x_4, w_7 = \bar{x}_3x_4, w_8 = \bar{x}_3x_5, w_9 = \bar{x}_1x_2x_3, w_{10} = \bar{x}_1x_3x_4, w_{11} = \bar{x}_2x_3x_4, t_{12} = x_1x_2x_5, w_{13} = \bar{x}_1x_3x_5, t_{14} = x_1x_4x_5, t_{15} = x_2x_3x_5, w_{16} = \bar{x}_2x_4x_5, t_{17} = x_3x_4x_5$

$$\text{CP4: Max } -x_1 - 2x_2 - 3x_3 - 5x_4 - 3x_5 + t_1 + 3t_2 + w_3 + w_4 + 2w_5 + 3t_6 + 3w_7 + 2w_8 + 2w_9 + w_{10} + w_{11} + t_{12} + w_{13} + t_{14} + t_{15} + w_{16} + t_{17}$$

s.t.

$$\begin{array}{lll} x_1 + \bar{x}_1 = 1 & x_2 + \bar{x}_2 = 1 & x_3 + \bar{x}_3 = 1 \\ t_1 \leq x_1 & & t_1 \leq x_2 \\ t_2 \leq x_1 & & t_2 \leq x_3 \\ w_3 \leq \bar{x}_1 & & w_3 \leq x_4 \\ w_4 \leq \bar{x}_1 & & w_4 \leq x_5 \\ w_5 \leq \bar{x}_2 & & w_5 \leq x_3 \\ t_6 \leq x_2 & & t_6 \leq x_4 \\ w_7 \leq \bar{x}_3 & & w_7 \leq x_4 \\ w_8 \leq \bar{x}_3 & & w_8 \leq x_5 \\ w_9 \leq \bar{x}_1 & & w_9 \leq x_2 & w_9 \leq x_3 \\ w_{10} \leq \bar{x}_1 & & w_{10} \leq x_3 & w_{10} \leq x_4 \\ w_{11} \leq \bar{x}_2 & & w_{11} \leq x_3 & w_{11} \leq x_4 \\ t_{12} \leq x_1 & & t_{12} \leq x_2 & t_{12} \leq x_5 \\ w_{13} \leq \bar{x}_1 & & w_{13} \leq x_3 & w_{13} \leq x_5 \\ t_{14} \leq x_1 & & t_{14} \leq x_2 & t_{14} \leq x_5 \\ t_{15} \leq x_2 & & t_{15} \leq x_3 & t_{15} \leq x_5 \\ w_{16} \leq \bar{x}_2 & & w_{16} \leq x_4 & w_{16} \leq x_5 \\ t_{17} \leq x_3 & & t_{17} \leq x_4 & t_{17} \leq x_5 \\ x_1 \geq 0 & x_2 \geq 0 & x_3 \geq 0 & x_4 \geq 0 & x_5 \geq 0 & x_4 \leq 1 & x_5 \leq 1 & \bar{x}_1 \geq 0 & \bar{x}_2 \geq 0 & \bar{x}_3 \geq 0 \end{array}$$

By using *CPLEX*, we find the solution of the relaxed problem is $x_1 = 0, x_2 = x_3 = x_4 = x_5 = 0.5$ with the objective value $Z_{CP4} = 3.5$. The upper bound of the primal problem becomes 3.5.

Iteration 1:

(1) We set up an occurrence table as below:

	x_1	x_2	x_3	x_4	x_5
+ve	4	4	3	4	5
-ve	6	4	7	6	4

(2) Since there is no variable that contains only positive or negative occurrence, we choose x_5 to be the branching variable and set it at 1.

(3) The constraint can be reduced as

$$(I): -2x_1 - 2x_2 - 2x_3 + 2x_1x_2 + 2x_1x_3 + x_2x_3 + 2x_2x_4 - 2x_1x_2x_3 - x_1x_3x_4 - x_2x_3x_4 \geq 1$$

(4) Since the *RHS* of the constraint is positive and the *LHS* equals to -3, we try the revised bound rule to find out the solution of the subproblem and find out its upper bound.

(5) We set up the P4 and CP4 of the subproblem as:

$$\text{P4: Max } -2x_1 - 2x_2 - 3x_3 - 2x_4 + 2x_1x_2 + 2x_1x_3 + \bar{x}_2x_3 + 2x_2x_4 + 2\bar{x}_3x_4 + 2\bar{x}_1x_2x_3 + \bar{x}_1x_3x_4 + \bar{x}_2x_3x_4$$

s.t.

$$\begin{array}{lll} x_1 + \bar{x}_1 = 1 & x_2 + \bar{x}_2 = 1 & x_3 + \bar{x}_3 = 1 \\ x_1x_2 \leq x_1 & & x_1x_2 \leq x_2 \\ x_1x_3 \leq x_1 & & x_1x_3 \leq x_3 \\ \bar{x}_2x_3 \leq \bar{x}_2 & & \bar{x}_2x_3 \leq x_3 \\ x_2x_4 \leq x_2 & & x_2x_4 \leq x_4 \\ \bar{x}_3x_4 \leq \bar{x}_3 & & \bar{x}_3x_4 \leq x_4 \\ \bar{x}_1x_2x_3 \leq \bar{x}_1 & & \bar{x}_1x_2x_3 \leq x_2 \quad \bar{x}_1x_2x_3 \leq x_3 \\ \bar{x}_1x_3x_4 \leq \bar{x}_1 & & \bar{x}_1x_3x_4 \leq x_3 \quad \bar{x}_1x_3x_4 \leq x_4 \\ \bar{x}_2x_3x_4 \leq \bar{x}_2 & & \bar{x}_2x_3x_4 \leq x_3 \quad \bar{x}_2x_3x_4 \leq x_4 \\ x_1 \geq 0 \quad x_2 \geq 0 \quad x_3 \geq 0 \quad x_4 \geq 0 & x_4 \leq 1 & \bar{x}_1 \geq 0 \quad \bar{x}_2 \geq 0 \quad \bar{x}_3 \geq 0 \\ x_1, x_2, x_3, x_4, \bar{x}_1, \bar{x}_2, \bar{x}_3 \text{ binary} & & \end{array}$$

Let $t_1 = x_1x_2, t_2 = x_1x_3, w_3 = \bar{x}_2x_3, t_4 = x_2x_4, w_5 = \bar{x}_3x_4, w_6 = \bar{x}_1x_2x_3, w_7 = \bar{x}_1x_3x_4, w_8 = \bar{x}_2x_3x_4$

$$\text{CP4: Max } -2x_1 - 2x_2 - 3x_3 - 2x_4 + 2t_1 + 2t_2 + w_3 + 2t_4 + 2w_5 + 2w_6 + w_7 + w_8$$

s.t.

$$\begin{array}{lll} x_1 + \bar{x}_1 = 1 & x_2 + \bar{x}_2 = 1 & x_3 + \bar{x}_3 = 1 \\ t_1 \leq x_1 & & t_1 \leq x_2 \\ t_2 \leq x_1 & & t_2 \leq x_3 \\ w_3 \leq \bar{x}_2 & & w_3 \leq x_3 \\ t_4 \leq x_2 & & t_4 \leq x_4 \\ w_5 \leq \bar{x}_3 & & w_5 \leq x_4 \\ w_6 \leq \bar{x}_1 & & w_6 \leq x_2 \quad w_6 \leq x_3 \\ w_7 \leq \bar{x}_1 & & w_7 \leq x_3 \quad w_7 \leq x_4 \\ w_8 \leq \bar{x}_2 & & w_8 \leq x_3 \quad w_8 \leq x_4 \\ x_1 \geq 0 \quad x_2 \geq 0 \quad x_3 \geq 0 \quad x_4 \geq 0 & x_4 \leq 1 & \bar{x}_1 \geq 0 \quad \bar{x}_2 \geq 0 \quad \bar{x}_3 \geq 0 \end{array}$$

(6) By using *CPLEX*, we find the solution of subproblem (I) is $x_1 = x_2 = x_3 = x_4 = 0.5$ with the objective value $Z_{CP4} = 2$

(7) Since $Z_{CP4} > RHS_{subproblem}$, we continue branching and set the upper bound as 2.

Iteration 2:

(1) We set up an occurrence table as below:

	x_1	x_2	x_3	x_4
+ve	2	3	2	1
-ve	3	3	4	2

(2) Since there is no variable that contains only positive occurrence or negative occurrence, we choose x_2 to be the branching variable and set x_2 at 1.

(3) The constraint can be reduced as

$$(II): -x_3 + 2x_4 - x_3x_4 - x_1x_3x_4 \geq 3$$

(4) Since the *RHS* of the constraint is positive and the *LHS* equals to -1, we try the revised bound rules to find out the solution of the subproblem and its upper bound.

(5) We set up the P4 and CP4 of the subproblem as:

$$P4: \text{Max } -x_3 + 2\bar{x}_3x_4 + \bar{x}_1x_3x_4$$

s.t.

$$\begin{aligned} x_1 + \bar{x}_1 &= 1 & x_3 + \bar{x}_3 &= 1 \\ \bar{x}_3x_4 &\leq \bar{x}_3 & \bar{x}_3x_4 &\leq x_4 \\ \bar{x}_1x_3x_4 &\leq \bar{x}_1 & \bar{x}_1x_3x_4 &\leq x_3 & \bar{x}_1x_3x_4 &\leq x_4 \\ x_1 \geq 0 & x_3 \geq 0 & x_4 \geq 0 & x_4 \leq 1 & \bar{x}_1 \geq 0 & \bar{x}_3 \geq 0 \\ x_1, x_3, x_4, \bar{x}_1, \bar{x}_3 & \text{ binary} \end{aligned}$$

$$\text{Let } w_1 = \bar{x}_3x_4, w_2 = \bar{x}_1x_3x_4$$

$$CP4: \text{Max } -x_3 + 2w_1 + w_2$$

s.t.

$$\begin{aligned} x_1 + \bar{x}_1 &= 1 & x_3 + \bar{x}_3 &= 1 \\ w_1 &\leq \bar{x}_3 & w_1 &\leq x_4 \\ w_2 &\leq \bar{x}_1 & w_2 &\leq x_3 & w_2 &\leq x_4 \\ x_1 \geq 0 & x_3 \geq 0 & x_4 \geq 0 & x_4 \leq 1 & \bar{x}_1 \geq 0 & \bar{x}_3 \geq 0 \end{aligned}$$

(6) By using *CPLEX*, we find the solution of subproblem (II) is $x_1 = x_3 = 0, x_4 = 1$ with the objective value $Z_{CP4} = 2$. Since $Z_{CP4} < RHS_{subproblem}$, the problem is infeasible and so we backtrack at $x_2 = 0$.

Backtrack at $x_2 = 0$:

(1) The constraint can be formed as

$$(III): -2x_1 - 2x_3 + 2x_1x_3 - x_1x_3x_4 \geq 1$$

(2) Since the *RHS* of the constraint is positive and the *LHS* equals to -3, we check with our bound rule.

(3) We set up the P4 and CP4 of the subproblem as:

$$P4: \text{Max } -2x_1 - 2x_3 - x_4 + 2x_1x_3 + \bar{x}_3x_4 + \bar{x}_1x_3x_4$$

s.t.

$$\begin{array}{ll} x_1 + \bar{x}_1 = 1 & x_3 + \bar{x}_3 = 1 \\ x_1x_3 \leq x_1 & x_1x_3 \leq x_3 \\ \bar{x}_3x_4 \leq \bar{x}_3 & \bar{x}_3x_4 \leq x_4 \\ \bar{x}_1x_3x_4 \leq \bar{x}_1 & \bar{x}_1x_3x_4 \leq x_3 \quad \bar{x}_1x_3x_4 \leq x_4 \\ x_1 \geq 0 \quad x_3 \geq 0 \quad x_4 \geq 0 & x_4 \leq 1 \quad \bar{x}_1 \geq 0 \quad \bar{x}_3 \geq 0 \\ x_1, x_3, x_4, \bar{x}_1, \bar{x}_3 \text{ binary} & \end{array}$$

$$\text{Let } t_1 = x_1x_3, w_2 = \bar{x}_3x_4, w_3 = \bar{x}_1x_3x_4$$

$$CP4: \text{Max } -2x_1 - 2x_3 - x_4 + 2t_1 + w_2 + w_3$$

s.t.

$$\begin{array}{ll} x_1 + \bar{x}_1 = 1 & x_3 + \bar{x}_3 = 1 \\ t_1 \leq x_1 & t_1 \leq x_3 \\ w_2 \leq \bar{x}_3 & w_2 \leq x_4 \\ w_3 \leq \bar{x}_1 & w_3 \leq x_3 \quad w_3 \leq x_4 \\ x_1 \geq 0 \quad x_3 \geq 0 \quad x_4 \geq 0 & x_4 \leq 1 \quad \bar{x}_1 \geq 0 \quad \bar{x}_3 \geq 0 \end{array}$$

(4) By using *CPLEX*, we find the solution of subproblem (III) is $x_1 = x_3 = 0, x_4 = 1$ with the objective value $Z_{CP4} = 0$

(5) Since $Z_{CP4} < RHS_{subproblem}$, we backtrack at $x_5 = 0$.

Backtrack at $x_5 = 0$:

(1) The constraint can be formed as

$$(IV): -x_1 - 2x_2 - x_3 - x_4 + x_1x_2 + 3x_1x_3 - x_1x_4 + 3x_2x_4 - x_3x_4 - 2x_1x_2x_3 - x_1x_3x_4 - x_2x_3x_4 \geq 1$$

(2) The *RHS* of the constraint is positive and the *LHS* value equals to -4.

(3) We set up the P4 and CP4 of the subproblem as:

$$P4: \text{Max } -x_1 - 2x_2 - 3x_3 - 5x_4 + x_1x_2 + 3x_1x_3 + \bar{x}_1x_4 + 2\bar{x}_2x_3 + 3x_2x_4 + 3\bar{x}_3x_4 + 2\bar{x}_1x_2x_3 + \bar{x}_1x_3x_4 + \bar{x}_2x_3x_4$$

s. t.

$$\begin{array}{lll} x_1 + \bar{x}_1 = 1 & x_2 + \bar{x}_2 = 1 & x_3 + \bar{x}_3 = 1 \\ x_1x_2 \leq x_1 & & x_1x_2 \leq x_2 \\ x_1x_3 \leq x_1 & & x_1x_3 \leq x_3 \\ \bar{x}_1x_4 \leq \bar{x}_1 & & \bar{x}_1x_4 \leq x_4 \\ \bar{x}_2x_3 \leq \bar{x}_2 & & \bar{x}_2x_3 \leq x_3 \\ x_2x_4 \leq x_2 & & x_2x_4 \leq x_4 \\ \bar{x}_3x_4 \leq \bar{x}_3 & & \bar{x}_3x_4 \leq x_4 \\ \bar{x}_1x_2x_3 \leq \bar{x}_1 & & \bar{x}_1x_2x_3 \leq x_2 \quad \bar{x}_1x_2x_3 \leq x_3 \\ \bar{x}_1x_3x_4 \leq \bar{x}_1 & & \bar{x}_1x_3x_4 \leq x_3 \quad \bar{x}_1x_3x_4 \leq x_4 \\ \bar{x}_2x_3x_4 \leq \bar{x}_2 & & \bar{x}_2x_3x_4 \leq x_3 \quad \bar{x}_2x_3x_4 \leq x_4 \\ x_1 \geq 0 \quad x_2 \geq 0 \quad x_3 \geq 0 \quad x_4 \geq 0 & x_4 \leq 1 & \bar{x}_1 \geq 0 \quad \bar{x}_2 \geq 0 \quad \bar{x}_3 \geq 0 \\ x_1, x_2, x_3, x_4, \bar{x}_1, \bar{x}_2, \bar{x}_3 \text{ binary} & & \end{array}$$

$$\text{Let } t_1 = x_1x_2, t_2 = x_1x_3, w_3 = \bar{x}_1x_4, w_4 = \bar{x}_2x_3, t_5 = x_2x_4, w_6 = \bar{x}_3x_4, w_7 = \bar{x}_1x_2x_3, w_8 = \bar{x}_1x_3x_4, w_9 = \bar{x}_2x_3x_4$$

$$CP4: \text{Max } -x_1 - 2x_2 - 3x_3 - 5x_4 + t_1 + 3t_2 + w_3 + 2w_4 + 3t_5 + 3w_6 + 2w_7 + w_8 + w_9$$

s. t.

$$\begin{array}{llll}
x_1 + \bar{x}_1 = 1 & x_2 + \bar{x}_2 = 1 & x_3 + \bar{x}_3 = 1 & \\
t_1 \leq x_1 & & t_1 \leq x_2 & \\
t_2 \leq x_1 & & t_2 \leq x_3 & \\
w_3 \leq \bar{x}_1 & & w_3 \leq x_4 & \\
w_4 \leq \bar{x}_2 & & w_4 \leq x_3 & \\
t_5 \leq x_2 & & t_5 \leq x_4 & \\
w_6 \leq \bar{x}_3 & & w_6 \leq x_4 & \\
w_7 \leq \bar{x}_1 & & w_7 \leq x_2 & w_7 \leq x_3 \\
w_8 \leq \bar{x}_1 & & w_8 \leq x_3 & w_8 \leq x_4 \\
w_9 \leq \bar{x}_2 & & w_9 \leq x_3 & w_9 \leq x_4 \\
x_1 \geq 0 & x_2 \geq 0 & x_3 \geq 0 & x_4 \geq 0 & x_4 \leq 1 & \bar{x}_1 \geq 0 & \bar{x}_2 \geq 0 & \bar{x}_3 \geq 0
\end{array}$$

(4) By using *CPLEX*, we find the solution of subproblem (IV) is $x_1 = x_2 = x_3 = x_4 = 0.5$ with the objective value $Z_{CP4} = 3$.

(5) Since $Z_{CP4} > RHS_{subproblem}$, we continue branching and set the upper bound as 3.

Iteration 3:

(1) We set up an occurrence table as below:

	x_1	x_2	x_3	x_4
+ve	2	2	1	1
-ve	4	3	5	5

(2) Since there is no variable that contains only positive or negative occurrence, we choose x_1 to be the branching variable and set it at 1.

(3) The constraint can be reduced as

$$(V): -x_2 + 2x_3 - 2x_4 - 2x_2x_3 + 3x_2x_4 - 2x_3x_4 - x_2x_3x_4 \geq 2$$

(4) Since the *RHS* of the constraint is positive and the *LHS* equals to -3, we check the bound rule.

(5) We set up the P4 and CP4 of the subproblem as:

$$\begin{array}{l}
\text{P4: Max } -x_2 - 5x_4 + 2\bar{x}_2x_3 + 3x_2x_4 + 3\bar{x}_3x_4 + \bar{x}_2x_3x_4 \\
\text{s.t.}
\end{array}$$

$$\begin{array}{ll}
x_2 + \bar{x}_2 = 1 & x_3 + \bar{x}_3 = 1 \\
\bar{x}_2 x_3 \leq \bar{x}_2 & \bar{x}_2 x_3 \leq x_3 \\
x_2 x_4 \leq x_2 & x_2 x_4 \leq x_4 \\
\bar{x}_3 x_4 \leq \bar{x}_3 & \bar{x}_3 x_4 \leq x_4 \\
\bar{x}_2 x_3 x_4 \leq \bar{x}_2 & \bar{x}_2 x_3 x_4 \leq x_3 \quad \bar{x}_2 x_3 x_4 \leq x_4 \\
x_2 \geq 0 \quad x_3 \geq 0 \quad x_4 \geq 0 & x_4 \leq 1 \quad \bar{x}_2 \geq 0 \quad \bar{x}_3 \geq 0 \\
x_2, x_3, x_4, \bar{x}_2, \bar{x}_3 \text{ binary} &
\end{array}$$

Let $w_1 = \bar{x}_2 x_3, t_2 = x_2 x_4, w_3 = \bar{x}_3 x_4, w_4 = \bar{x}_2 x_3 x_4$

CP4: Max $-x_2 - 5x_4 + 2w_1 + 3t_2 + 3w_3 + w_4$

s.t.

$$\begin{array}{lll}
x_2 + \bar{x}_2 = 1 & x_3 + \bar{x}_3 = 1 & \\
w_1 \leq \bar{x}_2 & w_1 \leq x_3 & \\
t_2 \leq x_2 & t_2 \leq x_4 & \\
w_3 \leq \bar{x}_3 & w_3 \leq x_4 & \\
w_4 \leq \bar{x}_2 & w_4 \leq x_3 & w_4 \leq x_4 \\
x_2 \geq 0 \quad x_3 \geq 0 \quad x_4 \geq 0 & x_4 \leq 1 & \bar{x}_2 \geq 0 \quad \bar{x}_3 \geq 0
\end{array}$$

(6) By using *CPLEX*, we find the solution of subproblem (V) is $x_2 = 0, x_3 = 0, x_5 = 1$ with the objective value $Z_{CP4} = 2$

(7) Since $Z_{CP4} = RHS_{subproblem}$, we stop the iterations and report a feasible solution of the original problem $x_1=1, x_2=0, x_3=1, x_4=0, x_5=0$.

6.3 Conclusion

From the above example, we know that the revised bound rule reduced many branches that may contain infeasible solutions. Also, we can prove the satisfiability problem in a shorter time. However, is there any further improvement in our branch-and-bound method? As we know, the shape of the searching tree is highly related to the order of the branching variable list. Thus, we will propose a revised branch rule in the next chapter to see whether we can have any further improvement.

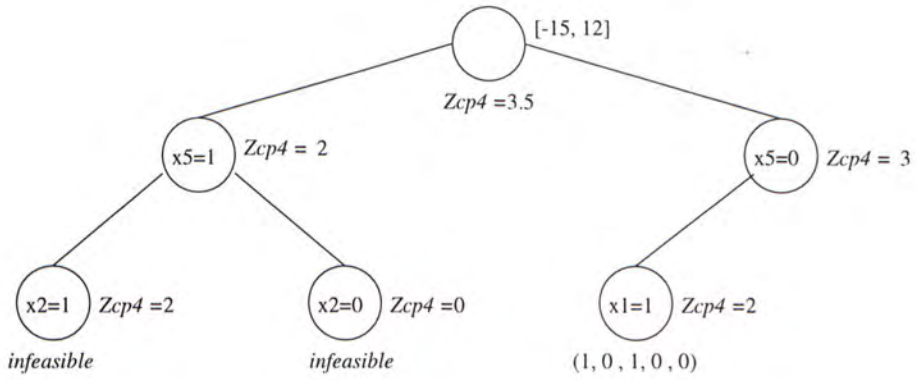

Figure 6.1: The solution tree for the revised bound rule of the problem $-x_1 - 2x_2 - x_3 - x_4 + x_1x_2 + 3x_1x_3 - x_1x_4 - x_1x_5 + 3x_2x_4 - x_3x_4 - x_3x_5 + x_4x_5 - 2x_1x_2x_3 - x_1x_3x_4 - x_2x_3x_4 + x_1x_2x_5 - x_1x_3x_5 + x_1x_4x_5 + x_2x_3x_5 - x_2x_4x_5 + x_3x_4x_5 \geq 1$ under our searching algorithm

Chapter 7

Revised Branch Rule for Branch-and-Bound Algorithm

In Chapters 5 and 6, we have developed a basic branch-and-bound algorithm and a revised bound rule. Although these two methods improve the traditional branch-and-bound method, their running time is still slow compared with other SAT searching methods. In this chapter, we will explain our revised branch rule and compare it with those we discussed in last two chapters. Moreover, we will test the performance of the revised branch rule combined with the revised bound rule in last chapter.

7.1 Revised Branch Rule

In Chapter 5, we define a branch rule by considering the positive occurrence of the variables. This method may be improper because the elimination of a variable would affect other variables in both the positive and negative terms. It can be improved by considering both the positive and negative occurrences.

From [15], Chu-Min Li suggested to use Freeman's method [6] to set the branching

variable by considering the weight of the variables. The weight can be evaluated by the following formula :

$$\boxed{H(x) = w(x) * w(\bar{x}) * 1024 + w(x) + w(\bar{x})}$$

where $w(x)$ is the number of clauses reduced if we set x at 1 and $w(\bar{x})$ is the number of clauses reduced if we set x at 0. Obviously, the contribution is to give more importance to the product $w(x) * w(\bar{x})$ to balance the search tree. The value of 1024 may be used for a quick multiplication because $1024 = 2^{10}$.

In this thesis, we would modify this formula to:

$$\boxed{W(x) = [w(x) * w(\bar{x}) * n + w(x) + w(\bar{x})] * priority(x)}$$

where $w(x)$ is the number of positive occurrence of the variable, x , $w(\bar{x})$ is the number of negative occurrence of x and n is the number of variables in the problem. Initially, the $priority(x)$ is set to 1. After processing the CP4, we can find out whether x is integral. From the literature, the value branching variable should be non-integral from the relaxed problem. Here, we also prefer to branch on a non-integer variable. If x is an integer, we set $priority(x) = 0$. Otherwise, we set $priority(x) = 1$. If there are more than one variable that contain the same weight, we would randomly choose one of them. This randomization approach, instead of branching on the *best* variable, enables our algorithm to find a feasible solution quicker.

In addition, we have to decide whether to set the branching variable as 0 or 1. Let us consider the linear term of the branching variable. If it is positive, we set the branching variable at 1. Otherwise, we set it at 0. Fang and Loetamonphong [39] proved that the cost vectors c_i are effective in a constrained problem. In a minimization problem, if c_i is larger than zero, we should set x_i^* at its lower bound. Otherwise, we should set x_i^* as its upper bound. Therefore, the assignment of the branching

Revised Branch Rule

- (1) Evaluate the weight of each variable $x_i, i = 1, \dots, n$ by using the formula $W(x_i) = [w(x_i) * w(\bar{x}_i) * n + w(x_i) + w(\bar{x}_i)] * priority(x_i)$ where $priority(x_i) = 0$ if x_i is an integer in CP4 or $priority(x_i) = 1$ if x_i is not an integer in CP4.
- (2) (i) Choose the variable, x_i , with the highest weight as the branching variable.
(ii) If more than one variable have the highest weight, choose the branching variable x_i randomly among these variables.
- (3) (i) If the linear term of the branching variable is positive, eliminate it by setting $x_i = 1$.
(ii) Otherwise, set $x_i = 0$.

Table 7.1: Revised Branch Rule for the CSP

variables should be considered in the sign of the linear term in the constraint. The revised branch rule and the revised branch-and-bound algorithm is shown in Table 7.1 and Table 7.2.

7.2 Comparison between Branch Rule and Revised Branch Rule

In [15], Chu-Min Li proved that the width of a search tree is more important than its mean height. The width and the shape of the search tree are highly related to the order in eliminating variables. When n is small, the searching tree is shallow. That is, we can find the solution in a short running time no matter how the ordering is. However, if n becomes larger, the ordering would be more significant. The weight of the product $w(x) * w(\bar{x})$ would be heavier. For example, the positive occurrence and negative occurrence of x_1 are 3 and 5, respectively, and those of x_2 are 4 and 4, respectively. If n equals to 5, the weights of x_1 and x_2 are 83 and 88, respectively.

Revised Searching Algorithm for CSP

Procedure:

- (1) (i) If the RHS of the constraint is non-positive, set the unassigned variable to be 0. Stop and go to (10).
- (1) (ii) If the sum of all the coefficient of the constraint is larger than the RHS, set the unassigned variable to be 1. Stop and go to (10).
- (2) Use the *Revised Bound Rule* to check whether the original problem is feasible and find its upper bound.
- (3) Calculate the number of occurrence of each variable in the constraint according to
 - (i) positive coefficient
 - (ii) negative coefficient
- (4) (i) If the number of occurrence of variable in (3)(i) is 0, then we set that variable to 0.
- (4) (ii) If the number of occurrence of variable in (3)(ii) is 0, then we set that variable to 1.
- (4) (iii) Go to (6).
- (5) Use the *Revised Branch Rule* to find the branching variable and eliminate this branching variable.
- (6) Update the constraint.
- (7) (i) If the RHS of the constraint is non-positive, set the unassigned variable to be 0. Stop and go to (10).
- (7) (ii) If the sum of all the coefficient in LHS of the constraint is larger than the RHS, set the unassigned variable to be 1. Stop and go to (10).
- (8) (i) Use the *Revised Bound Rule* to figure out the upper bound of the subproblem.
- (8) (ii) If a solution is found or all the nodes have been reached, stop and go to (10).
- (8) (iii) If dead end is reached, backtrack to the latest node.
- (9) Go back to (3).
- (10) Return the feasibility of the problem and the feasible solution if it is satisfiable.

Revised Branch Rule

- (1) Evaluate the weight of each variable x_i , $i = 1, \dots, n$ by using the formula $W(x_i) = [w(x_i) * w(\bar{x}_i) * n + w(x_i) + w(\bar{x}_i)] * priority(x_i)$ where $priority(x_i) = 0$ if x_i is an integer in CP4 and $priority(x_i) = 1$ if x_i is a non-integer.
- (2) (i) Choose the variable, x_i , with the highest weight as the branching variable.
- (2) (ii) If more than one variables have the same highest weight, choose the branching variable x_i randomly among these variables.
- (3) (i) If the linear term of the branching variable is positive, eliminate it by setting $x_i = 1$.
- (3) (ii) Otherwise, set $x_i = 0$.

<i>Revised Bound Rule</i>	
(1)	Transform the subproblem into P4 and CP4 and solve the CP4 by using <i>CPLEX</i> .
(2)	If x is an integer solution, i.e. P4 and CP4 are consistent, <ul style="list-style-type: none"> (i) if $Z_{CP4} \geq RHS_{subproblem}$, return x as the feasible solution of the original problem. (ii) if $Z_{CP4} < RHS_{subproblem}$, the sub-problem is infeasible and backtrack to the previous node.
(3)	If x is not an integer solution, i.e. P4 and CP4 are inconsistent, <ul style="list-style-type: none"> (i) Z_{CP4} is the upper bound of the subproblem. (ii) if $Z_{CP4} < RHS_{subproblem}$, then stop and return the subproblem as infeasible and backtrack to the previous node. (iii) if $Z_{CP4} \geq RHS_{subproblem}$, we continue branching.

Table 7.2: Revised Branch-and-Bound Algorithm for the CSP

However, if n equals 100, the difference between these two variables is larger (i.e. 1508 and 1608 respectively). Besides, when n becomes larger, the number of clauses generated would be larger. Thus, the number of occurrences (both positive and negative) would deviate from variables sharply. That means, we can find a better branching variable easier. On the contrary, if we only consider the weight of the positive occurrence of the variable, it would be ambiguous if more than one variable contain the same number of positive occurrence. A better branching variable can be found under our revised branch rule.

On the other hand, Chu-Min Li also proposed that branching on a variable randomly selected among the best variables may solve the problem faster. Our revised branch rule chooses one variable randomly among those variables with the same weight. This method is better than comparing the absolute coefficient among those variables. The elimination of the branching variable may affect other unassigned variables deeply in the last method. This changes the width of the search tree in the next

level and the shape of the whole searching tree.

Nevertheless, the revised branch rule considers whether to set the branching variable to 0 or 1 by considering the sign of its linear term. The shape of the search tree would be different and the width of the search tree can be reduced. Thus, we can find out the feasible solution of the original problem in a shorter running time. According to the above reasons, the revised branch rule should have a better performance. We can test it by using the example discussed in last two chapters.

7.3 Example

Refer to the example in last two chapters, the constraint is

$$-x_1 - 2x_2 - x_3 - x_4 + x_1x_2 + 3x_1x_3 - x_1x_4 - x_1x_5 + 3x_2x_4 - x_3x_4 - x_3x_5 + x_4x_5 - 2x_1x_2x_3 - x_1x_3x_4 - x_2x_3x_4 + x_1x_2x_5 - x_1x_3x_5 + x_1x_4x_5 + x_2x_3x_5 - x_2x_4x_5 + x_3x_4x_5 \geq 1$$

In the following, we will use the revised branch and bound rule to show the improvement of these two methods. Since the *RHS* of the constraint is positive and the *LHS* equals to 1, we set the upper and lower bound as 16 and -15, respectively. Before processing the search procedure, we check the satisfiability of the problem by using *CPLEX* and set up the P4 and CP4 format of the problem as

$$\begin{aligned} \text{P4: Max} \quad & -x_1 - 2x_2 - 3x_3 - 5x_4 - 3x_5 + x_1x_2 + 3x_1x_3 + \bar{x}_1x_4 + \bar{x}_1x_5 + 2\bar{x}_2x_3 + 3x_2x_4 + \\ & 3\bar{x}_3x_4 + 2\bar{x}_3x_5 + 2\bar{x}_1x_2x_3 + \bar{x}_1x_3x_4 + \bar{x}_2x_3x_4 + x_1x_2x_5 + \bar{x}_1x_3x_5 + x_1x_4x_5 + x_2x_3x_5 + \\ & \bar{x}_2x_4x_5 + x_3x_4x_5 \end{aligned}$$

s.t.

$$\begin{array}{lll}
x_1 + \bar{x}_1 = 1 & x_2 + \bar{x}_2 = 1 & x_3 + \bar{x}_3 = 1 \\

By using *CPLEX*, we find the solution of relaxed problem is $x_1 = 0, x_2 = x_3 = x_4 = x_5 = 0.5$ with the objective value $Z_{CP4} = 3.5$. The priorities of the variables are

	x_1	x_2	x_3	x_4	x_5
priority	0	1	1	1	1

Iteration 1:

(1) We set up an occurrence table as below:

	x_1	x_2	x_3	x_4	x_5
+ve	4	4	3	4	5
-ve	6	4	7	6	4
$W(x)$	0	88	115	130	109

(2) Since there is no variable that contains only positive occurrence or negative occurrence, we choose x_4 to be the branching variable. Also, we should set x_4 at 0 because the sign of its linear term is negative.

(3) The constraint is reduced to

$$(I): -x_1 - 2x_2 - x_3 + x_1x_2 + 3x_1x_3 - x_1x_5 - x_3x_5 - 2x_1x_2x_3 + x_1x_2x_5 - x_1x_3x_5 + x_2x_3x_5 \geq 1$$

(4) Since the *RHS* of the constraint is positive and the *LHS* equals to -3, we try the revised bound rules to find out the solution of the subproblem and its upper bound.

(5) We set up the P4 and CP4 of the subproblem as:

$$\text{P4: Max } -x_1 - 2x_2 - 3x_3 - 3x_5 + x_1x_2 + 3x_1x_3 + \bar{x}_1x_5 + 2\bar{x}_2x_3 + 2\bar{x}_3x_5 + 2\bar{x}_1x_2x_3 + x_1x_2x_5 + \bar{x}_1x_3x_5 + x_2x_3x_5$$

s.t.

$$\begin{array}{lll} x_1 + \bar{x}_1 = 1 & x_2 + \bar{x}_2 = 1 & x_3 + \bar{x}_3 = 1 \\ x_1x_2 \leq x_1 & x_1x_2 \leq x_2 & \\ x_1x_3 \leq x_1 & x_1x_3 \leq x_3 & \\ \bar{x}_1x_5 \leq \bar{x}_1 & \bar{x}_1x_5 \leq x_5 & \\ \bar{x}_2x_3 \leq \bar{x}_2 & \bar{x}_2x_3 \leq x_3 & \\ \bar{x}_3x_5 \leq \bar{x}_3 & \bar{x}_3x_5 \leq x_5 & \\ \bar{x}_1x_2x_3 \leq \bar{x}_1 & \bar{x}_1x_2x_3 \leq x_2 & \bar{x}_1x_2x_3 \leq x_3 \\ x_1x_2x_5 \leq x_1 & x_1x_2x_5 \leq x_2 & x_1x_2x_5 \leq x_5 \\ \bar{x}_1x_3x_5 \leq \bar{x}_1 & \bar{x}_1x_3x_5 \leq x_3 & \bar{x}_1x_3x_5 \leq x_5 \\ x_2x_3x_5 \leq x_2 & x_2x_3x_5 \leq x_2 & x_2x_3x_5 \leq x_5 \\ x_1 \geq 0 & x_2 \geq 0 & x_3 \geq 0 & x_5 \geq 0 & x_5 \leq 1 & \bar{x}_1 \geq 0 & \bar{x}_2 \geq 0 & \bar{x}_3 \geq 0 \\ x_1, x_2, x_3, x_5, \bar{x}_1, \bar{x}_2, \bar{x}_3 \text{ binary} & & & & & & & \end{array}$$

Let $t_1 = x_1x_2, t_2 = x_1x_3, w_3 = \bar{x}_1x_5, w_4 = \bar{x}_2x_3, w_5 = \bar{x}_3x_5, w_6 = \bar{x}_1x_2x_3, t_7 = x_1x_2x_5, w_8 = \bar{x}_1x_3x_5, t_9 = x_2x_3x_5$

$$\text{CP4: Max } -x_1 - 2x_2 - 3x_3 - 3x_5 + t_1 + 3t_2 + w_3 + 2w_4 + 2w_5 + 2w_6 + t_7 + w_8 + t_9$$

s.t.

$$\begin{array}{lll} x_1 + \bar{x}_1 = 1 & x_2 + \bar{x}_2 = 1 & x_3 + \bar{x}_3 = 1 \\ t_1 \leq x_1 & t_1 \leq x_2 & \\ t_2 \leq x_1 & t_2 \leq x_3 & \\ w_3 \leq \bar{x}_1 & w_3 \leq \bar{x}_5 & \\ w_4 \leq \bar{x}_2 & w_4 \leq x_3 & \\ w_5 \leq \bar{x}_3 & w_5 \leq x_5 & \\ w_6 \leq \bar{x}_1 & w_6 \leq x_2 & w_6 \leq x_3 \\ t_7 \leq x_1 & t_7 \leq x_2 & t_7 \leq x_5 \\ w_8 \leq \bar{x}_1 & w_8 \leq x_3 & w_8 \leq x_5 \\ t_9 \leq x_2 & t_9 \leq x_3 & t_9 \leq x_5 \\ x_1 \geq 0 & x_2 \geq 0 & x_3 \geq 0 & x_5 \geq 0 & x_5 \leq 1 & \bar{x}_1 \geq 0 & \bar{x}_2 \geq 0 & \bar{x}_3 \geq 0 \end{array}$$

(6) By using *CPLEX*, we find the solution of subproblem (I) is $x_1 = x_2 = x_3 =$

$x_5 = 0.5$ with the objective value $Z_{CP4} = 2.5$. The priorities of the variables are

	x_1	x_2	x_3	x_5
priority	1	1	1	1

(7) Since $Z_{CP4} > RHS_{subproblem}$, we continue branching and set the upper bound as 2.5.

Iteration 2:

(1) We set up an occurrence table as below:

	x_1	x_2	x_3	x_5
+ve	3	3	2	2
-ve	4	2	4	3
$W(x)$	67	35	46	35

(2) Since there is no variable that contains only positive occurrence or negative occurrence, we choose x_1 to be the branching variable (x_1 has the largest weight). Also, we should set x_1 at 0 because the sign of its linear term is non-positive.

(3) The constraint can be reduced as

$$(II): -2x_2 - x_3 - x_3x_5 + x_2x_3x_5 \geq 1$$

(4) Since the *RHS* of the constraint is positive and the *LHS* equals to -3, we try the revised bound rules to find out the solution of the subproblem and its upper bound.

(5) We set up the P4 and CP4 of the subproblem as:

$$P4: \text{Max } -2x_2 - x_3 - x_5 + \bar{x}_3x_5 + x_2x_3x_5$$

s.t.

$$x_3 + \bar{x}_3 = 1$$

$$\bar{x}_3x_5 \leq \bar{x}_3$$

$$x_2x_3x_5 \leq x_2$$

$$x_2 \geq 0 \quad x_3 \geq 0 \quad x_5 \geq 0$$

$$x_2, x_3, x_5, \bar{x}_3 \text{ binary}$$

$$\bar{x}_3x_5 \leq x_5$$

$$x_2x_3x_5 \leq x_3$$

$$x_2x_3x_5 \leq x_5$$

$$x_2 \leq 1 \quad x_5 \leq 1 \quad \bar{x}_3 \geq 0$$

Let $w_1 = \bar{x}_3x_5, t_2 = x_2x_3x_5$

CP4: Max $-2x_2 - x_3 - x_5 + w_1 + t_2$

s.t.

$$\begin{aligned} x_3 + \bar{x}_3 &= 1 \\ w_1 &\leq \bar{x}_3 & w_1 &\leq x_5 \\ t_2 &\leq x_2 & t_2 &\leq x_3 & t_2 &\leq x_5 \\ x_2 \geq 0 \ x_3 \geq 0 \ x_5 \geq 0 & \quad x_2 \leq 1 \ x_5 \leq 1 & \quad \bar{x}_3 \geq 0 \end{aligned}$$

(6) By using *CPLEX*, we find the solution of subproblem (II) is $x_2 = x_3 = 0, x_5 = 1$ with the objective value $Z_{CP4} = 0$. Since $Z_{CP4} < RHS_{subproblem}$, the problem is infeasible and so we backtrack at $x_1 = 1$.

Backtrack at $x_1 = 1$:

(1) The constraint can be formed as

$$(III): -x_2 + 2x_3 - x_5 - 2x_2x_3 + x_2x_5 - 2x_3x_5 + x_2x_3x_5 \geq 2$$

(2) The *RHS* of the constraint is positive and the *LHS* value equals to -1 when all variables are set at 1.

(3) We set up the P4 and CP4 of the subproblem as:

P4: Max $-x_2 - 3x_5 + 2\bar{x}_2x_3 + x_2x_5 + 2\bar{x}_3x_5 + \bar{x}_2x_3x_5$

s.t.

$$\begin{aligned} x_2 + \bar{x}_2 &= 1 & x_3 + \bar{x}_3 &= 1 \\ \bar{x}_2x_3 &\leq \bar{x}_2 & \bar{x}_2x_3 &\leq x_3 \\ x_2x_5 &\leq x_2 & x_2x_5 &\leq x_5 \\ \bar{x}_3x_5 &\leq \bar{x}_3 & \bar{x}_3x_5 &\leq x_5 \\ \bar{x}_2x_3x_5 &\leq \bar{x}_2 & \bar{x}_2x_3x_5 &\leq x_3 & \bar{x}_2x_3x_5 &\leq x_5 \\ x_2 \geq 0 \ x_3 \geq 0 \ x_5 \geq 0 & \quad x_5 \leq 1 & \quad \bar{x}_2 \geq 0 \ \bar{x}_3 \geq 0 \\ x_2, x_3, x_5, \bar{x}_2, \bar{x}_3 & \text{ binary} \end{aligned}$$

Let $w_1 = \bar{x}_2x_3, t_2 = x_2x_5, w_3 = \bar{x}_3x_5, w_4 = \bar{x}_2x_3x_5$

CP4: Max $-x_2 - 3x_5 + 2w_1 + t_2 + 2w_3 + w_4$

s.t.

Figure 7.1: The solution tree for the revised branch-and-bound algorithm of the problem $-x_1 - 2x_2 - x_3 - x_4 + x_1x_2 + 3x_1x_3 - x_1x_4 - x_1x_5 + 3x_2x_4 - x_3x_4 - x_3x_5 + x_4x_5 - 2x_1x_2x_3 - x_1x_3x_4 - x_2x_3x_4 + x_1x_2x_5 - x_1x_3x_5 + x_1x_4x_5 + x_2x_3x_5 - x_2x_4x_5 + x_3x_4x_5 \geq 1$ under our searching algorithm

$$\begin{array}{lll}
 x_2 + \bar{x}_2 = 1 & x_3 + \bar{x}_3 = 1 & \\
 w_1 \leq \bar{x}_2 & w_1 \leq x_3 & \\
 t_2 \leq x_2 & t_2 \leq x_5 & \\
 w_3 \leq \bar{x}_3 & w_3 \leq x_5 & \\
 w_4 \leq \bar{x}_2 & w_4 \leq x_3 & w_4 \leq x_5 \\
 x_2 \geq 0 \ x_3 \geq 0 \ x_5 \geq 0 & x_5 \leq 1 & \bar{x}_2 \geq 0 \ \bar{x}_3 \geq 0
 \end{array}$$

(4) By using *CPLEX*, we find the solution of subproblem (III) is $x_3 = 1, x_2 = x_5 = 0$ with the objective value $Z_{CP4} = 2$. Since $Z_{CP4} = RHS_{subproblem}$, we stop here and report the problem is satisfiable with the solution $(x_1 = x_3 = 1, x_2 = x_4 = x_5 = 0)$.

7.4 Conclusion

From the above example, we observe that the revised branch rule gets a great improvement from the original branch-and-bound-algorithm. It is significant that nine steps

are saved compared with the basic branch-and-bound algorithm. In the next chapter, we will present experimental results and analysis from different sizes of problems. Moreover, we will compare our algorithm with other methods, like *SATZ*.

Chapter 8

Experimental Results and Analysis

In this chapter, experimental results for the three methods, the basic branch-and-bound method, the revised bound rule method and the revised branch-and-bound method, are presented in the first section. The statistics include the satisfiability of the problem, the mean and standard deviation of the computational time, the maximum number of backtracking and the maximum number of constraints generated in CP4. We discuss the performance of the three methods and compare them with *SATZ* under the same computing environment. We only present part of the results here and the complete results can be found in Appendix B. In the second section, we study the significance on the difference between our revised branch-and-bound method and *SATZ* and find out some reasons of outperformance of *SATZ*.

8.1 Experimental Results

Table 8.1, Table 8.2 and Table 8.3 list the mean and standard deviation of the computational time, the maximum number of backtracking and the maximum number of constraints generated in CP4 for $n=5$, $n=10$ and $n=30$ under 100 samples respec-

tively. All methods are written in C language and the samples are run under Sun Workstation, Ultra-60. In Table 8.1, 76 samples are satisfiable while 24 samples are unsatisfiable. In Table 8.2, 74 samples are satisfiable while 26 samples are unsatisfiable. In Table 8.3, 73 samples are satisfiable while 27 samples are unsatisfiable. From the results, we can see that the performance of the three methods are in the same level when n is small. When $n=5$ and 10, the basic branch-and-bound algorithm runs in the shortest time although its maximum number of backtracking is much larger than that of the revised bound rule and the revised branch-and-bound algorithm. These two methods may take longer time in running the *CPLEX* for bounding parts.

However, when n is larger (i.e. $n=30$), the revised branch-and-bound algorithm does the best in both the mean computational time and the maximum number of backtracking. Obviously, the completion time becomes less for a smaller number of backtracking. This finding agrees with what we state in Chapter 5 that the efficiency of a searching procedure is highly related to the order of labeling. It means that the decision for choosing a branching variable is significant in branch-and-bound algorithm.

Table 8.4 gives the computational result of *SATZ* by using the same data we used for testing the basic branch-and-bound algorithm, the revised bound rule and the revised branch-and-bound algorithm. From the result, we find that the mean computational time of *SATZ* is less than one second. In Appendix B, we can see that the running time of *SATZ* is within 2 seconds, which is 251 times faster than our revised branch-and-bound algorithm. In the next section, we will analyze the computational result of the four methods.

Method	Mean Completion Time (sec.)	Standard Deviation of Computational Time (sec.)	Maximum number of Backtracking	Maximum number of Constraints in CP4

8.2 Statistical Analysis

In last section, we know that our revised branch-and-bound algorithm has a great improvement when compared to the basic branch-and-bound algorithm and the revised bound rule method. In section 8.2.1, we will discuss the performance of the above methods. Also from Table 8.4 and Appendix B, we know that *SATZ* implemented by Chu-Min Li runs much faster than our methods. We will talk over how it works in section 8.2.2.

8.2.1 Analysis of Search Techniques

From Appendix B, we can see that our basic branch-and-bound algorithm has the shortest running time when n is small (i.e. $n=5, 10$). The basic algorithm takes less than 0.01 seconds to complete all the samples. However, its number of backtracking is more than the revised bound rule method and the revised branch-and-bound algorithm. The maximum number of backtracking is 20 and 382 for $n=5$ and 10, respectively while they are 6 and 48 in the revised bound rule for $n=5$ and 10, respectively and they are 7 and 31 in the revised algorithm for $n=5$ and 10, respectively. Obviously, the latter two methods take time to find out the upper bound of the subproblems by using *CPLEX*. The computational time of these two methods may be larger than that of the basic algorithm although the number of backtracking of these two methods is smaller than that of the basic algorithm. However, when n is large (i.e. $n=30$), the order of variable labeling would be significant. As we state in Chapters 3 and 7, the choice of next branching variable may affect the efficiency for finding the feasible solution of the problem. A better branch rule is necessary for a large and hard problem.

Let us look at the results for the revised bound rule method and the revised branch-and-bound algorithm. Our revised branch-and-bound algorithm has an improvement especially when n becomes large. We can see that both two methods have the same degree of performance for $n=5$ from Appendix B. The revised bound rule method runs faster in 27 samples out of 100 while the revised branch-and-bound algorithm does 40. They have the same computational time in 33 samples. In that 27 samples, where the revised bound rule method does better, there are 3 samples that the revised branch-and-bound algorithm has smaller number of backtracking. The revised branch-and-bound algorithm may consume more time in computing the weight formula as we state in Chapter 7.

For $n=10$, the revised branch-and-bound algorithm does better than the revised bound rule method. There are 57 samples that our revised branch-and-bound algorithm has a shorter computational time while 31 samples that the revised bound rule method does better. In these 31 samples, where the revised bound rule method has a better performance, the number of backtracking of our revised branch-and-bound algorithm is smaller than that of the revised bound rule method. Evidently, our revised branch-and-bound algorithm produces a shorter enumeration tree during execution. On the other hand, we can see that the revised branch-and-bound algorithm performs much better for $n=30$. There are 83 samples that our revised algorithm has both a shorter computational time and a smaller number of backtracking, and there are 15 samples that the revised algorithm runs less than 10 seconds. In sample 50, 69, and 86, our revised algorithm runs at around 2 seconds when the revised bound rule takes more than 100 seconds. Clearly, the revised branch rule is powerful in general.

8.2.2 Discussion of the Performance of *SATZ*

The *SATZ* implemented by Chu-Min Li is a powerful solution scheme in SAT, especially when n is large. From Appendix B, we can see that *SATZ* takes at most 1.6 seconds for computing a sample with 30 variables. Why is *SATZ* so efficient especially when n is large? For any 3-SAT problem, every clause contains only three literals. That means, we can easily figure out whether the problem is feasible after several eliminations. Let's consider an example with 5 variables and 5 clauses.

$$x_1 \vee x_2 \vee x_5 \quad (1)$$

$$x_2 \vee x_3 \vee \bar{x}_4 \quad (2)$$

$$x_1 \vee \bar{x}_2 \vee \bar{x}_3 \quad (3)$$

$$\bar{x}_2 \vee x_4 \vee x_5 \quad (4)$$

$$\bar{x}_3 \vee \bar{x}_4 \vee \bar{x}_5 \quad (5)$$

First, we evaluate the weight of each variable by using the formula

$$H(x) = w(x) * w(\bar{x}) * 1024 + w(x) + w(\bar{x})$$

and the weights are

variable	x_1	x_2	x_3	x_4	x_5
weight	2	4100	2051	2051	2051

Since x_1 has the only positive occurrence, we better set $x_1 = 1$ and the problem reduces as

$$\text{T} \quad (1)$$

$$x_2 \vee x_3 \vee \bar{x}_4 \quad (2)$$

$$\text{T} \quad (3)$$

$$\bar{x}_2 \vee x_4 \vee x_5 \quad (4)$$

$$\bar{x}_3 \vee \bar{x}_4 \vee \bar{x}_5 \quad (5)$$

and the weights for the remaining variables are

variable	x_2	x_3	x_4	x_5
weight	1026	1026	2051	1026

We now set $x_4=0$ as the number of negative occurrence is larger and the problem becomes

$$\begin{array}{ll} T & (1) \\ T & (2) \\ T & (3) \\ \bar{x}_2 \vee F \vee x_5 & (4) \\ T & (5) \end{array}$$

Obviously, we choose x_5 or x_2 as our next branching variable so that (4) is satisfiable.

We can set $x_5=1$ and so the problem becomes satisfiable.

$$\begin{array}{ll} T & (1) \\ T & (2) \\ T & (3) \\ T & (4) \\ T & (5) \end{array}$$

We can easily see that *SATZ* is very powerful for 3-SAT problem. If the number of variables, n , is large, i.e. the number of clauses is large, we can find out whether the subproblem is satisfiable after doing three to four times of eliminations. We backtrack earlier even the problem is hard.

Chapter 9

Concluding Remarks

We conclude the thesis by stating our contributions and possible directions for future research.

9.1 Conclusion

The contributions of our work can be summarized as follows. We derive a two-step transformation for converting any 3-CNF-SAT problem into a singly-constrained zero-one polynomial problem. With the help of this transformation, techniques in solving integer programming problem, such as branch-and-bound method, can be applied directly for finding the satisfiability of the original CNF-SAT problem. Based on the transformed singly-constrained zero-one polynomial problem, we propose our branch-and-bound algorithm in solving the SAT problem. Revised branch-and-bound rules are suggested to increase the efficiency.

In the literature, there are several transformations for converting CNF-SAT problem into an integer programming problem. These transformations usually produce extra variables and constraints that enlarge the storage size. Luckily, no additional

variables and constraints are generated during our transformation and only a single surrogate constraint is formed at the end of the transformation. The storage space is smaller compared with other IP transformations. However, information may be lost in the proposed singly-constrained problem. For the 3-CNF-SAT problem, there are only 3 literals in each clause. Information gap exists between the two kinds of problems although they are equivalent.

Branch-and-bound method is suggested in solving the singly-constrained zero-one polynomial problem. Both revised bound and branch rules are proposed in Chapter 6 and 7, respectively. The basic branch-and-bound algorithm can solve a small-size problem in a short running time. It is ineffective for a large problem because of the loose bound and the weak branch rule. The solution tree becomes deeper when n is large and so the algorithm performs poorly. The revised bound rule provides a tighter upper bound for the subproblems so that backtracking can be carried out earlier. Furthermore, *CPLEX* is a strong solver in solving linear programming problems. It is used to find out the upper bound of the subproblems after relaxing. So, the computational time is shortened after using *CPLEX*. In addition, the weight formula in the revised branch rule can be used to obtain a better branching variable which balances the enumeration tree. Thus, the feasible solution can be figured out quickly. As a result, the revised branch-and-bound algorithm is more efficient.

9.2 Suggestions for Future Research

Our work represents a major step toward the understanding of satisfiability problem and integer programming problem. The two-step transformation provides a new way for tackling the satisfiability problem. However, the resulting singly-constrained

problem after the transformation may lose the structural property of the 3-CNF-SAT problem. The 3-CNF-SAT problem has a special structure: each clause contains exactly three literals. It is easy to figure out the satisfiability of the problem after several eliminations in general. The solution tree is short such that backtracking may occur earlier in every subproblem. On the other hand, the singly-constrained problem includes n variables in a single constraint and it may become inefficient when n is large. The enumeration tree is relatively large and backtracking may happen in a deeper level. Thus, a new approach is needed. Remaining m constraints after converting the 3-CNF clauses into integer programming format may be applicable since each new constraint contains at most three variables. This reformulated problem may be easier to solve.

Nevertheless, we can determine the next branching variable by using the idea in [5]. Considering the singly-constrained polynomial problem in Chapter 4, 5, 6 and 7¹, we can first evaluate the sum of all coefficient of the terms involving each variable and form the table

	x_1	x_2	x_3	x_4	x_5
Sum	-1	-1	-3	0	1

Then we choose the variable with the largest absolute sum, x_3 , as the next branching variable. Next, we differentiate $f(x)$ with respect to x_3 and get

$$\frac{\partial f}{\partial x_3} = -1 + 3x_1 - x_4 - x_5 - 2x_1x_2 - x_1x_4 - x_2x_4 - x_1x_5 + x_2x_5 + x_4x_5$$

After converting it into CP4 format, we can use *CPLEX* to find out its upper and lower bounds which are 2 and -8, respectively. Since the absolute value of the lower bound is larger than the lower bound, we set $x_3 = 0$. The subproblem becomes

¹The singly-constrained polynomial problem is $f(x) = -x_1 - 2x_2 - x_3 - x_4 + x_1x_2 + 3x_1x_3 - x_1x_4 - x_1x_5 + 3x_2x_4 - x_3x_4 - x_3x_5 + x_4x_5 - 2x_1x_2x_3 - x_1x_3x_4 - x_2x_3x_4 + x_1x_2x_5 - x_1x_3x_5 + x_1x_4x_5 + x_2x_3x_5 - x_2x_4x_5 + x_3x_4x_5 \geq 1$

$$f_1(x) = -x_1 - 2x_2 - x_4 + x_1x_2 - x_1x_4 - x_1x_5 + 3x_2x_4 + x_4x_5 + x_1x_2x_5 + x_1x_4x_5 - x_2x_4x_5 \geq 1$$

By using *CPLEX*, we find that the solution of the subproblem is $x_1 = x_2 = x_4 = x_5 = 0.5$ with $Z_{CP4} = 1.5$. Since it is feasible, we continue branching by setting up the table

	x_1	x_2	x_4	x_5
Sum	0	2	2	1

Now, we choose x_2 as the branching variable because x_2 has a term containing the largest absolute coefficient in $f_1(x)$. We differentiate $f_1(x)$ w.r.t. x_2 and get

$$\frac{\partial f_1(x)}{\partial x_2} = -2 + x_1 + 3x_4 + x_1x_5 - x_4x_5.$$

Since the upper and lower bounds are 2 and -3, respectively, we set $x_2 = 0$. We simplify the subproblem as

$$f_2(x) = -x_1 - x_4 - x_1x_4 + x_4x_5 + x_1x_4x_5 \geq 1$$

and find that Z_{CP4} of the objective function is 0. The subproblem is infeasible and we backtrack at $x_2 = 1$. The subproblem becomes

$$f_3(x) = 2x_4 - x_1x_4 + x_1x_4x_5 \geq 3$$

which is also infeasible because its $Z_{CP4} = 2$. So, we backtrack at $x_3 = 1$. By using *CPLEX*, we find that the problem is feasible with the solution $(1,0,1,0,0)$. This approach helps us to get more information of how the branching variable effects in the objective function. Backtracking occurs earlier under this consideration.

Appendix A

Searching Procedures for Solving Constraint Satisfaction Problem (CSP)

The present appendix is devoted to the presentation of some tree search procedures in solving CSPs. These procedures include *generate and test*, *standard backtracking*, *forward checking* and *looking ahead*. For convenience, we restricted our scope in the area of binary CSPs.

A.1 Notation

Let x_1, x_2, \dots, x_n be the variables occurring in the binary CSP with their domains D_1, D_2, \dots, D_n on the binary values. Let $C_{ij}(x_i, x_j)$ be the constraint between the variables x_i and x_j where $i < j$. We say that values v_i and v_j for variables x_i and x_j are consistent if and only if $C_{ij}(v_i, v_j)$ is true for $i \neq j$. Also, a value v_i for x_i is said to be consistent with the values v_1, \dots, v_k for the variables x_1, \dots, x_k iff values v_i and

<p>GENERATE AND TEST $P_k(v_1, \dots, v_k)$ is true for all $k < n$ iff</p> <ol style="list-style-type: none"> 1. $v_i \in D_i$ for $(1 \leq i \leq k)$.
--

Table A.1: Search Procedure for Generate and Test technique

v_j for variables x_i and x_j are consistent for $1 \leq j \leq k$.

A.2 Procedures for Solving CSP

In this section, we review 4 methods to solve the CSPs. In general, the searching procedure consists of testing whether (v_1, \dots, v_n) satisfies some property $P_n(v_1, \dots, v_n)$, where v_1, \dots, v_n are the values of x_1, \dots, x_n and P_n holds if all the constraints are satisfied for this assignment [40].

A.2.1 Generate and Test

“Generate and Test” is the reverse of the constraint and generate methodology [10]. It is the simplest way to find out the optimal solution of CSP. It first generates all the possible solutions and then tests them to see whether they satisfy all the constraints. The procedure is listed in Table A.1

However, “generate and test” is not an efficient way in solving CSP. All its constraints are only used to test whether the overall assignment is a solution or not. Actually, no pruning occurs in the search. Thus, it explores all the search space. On the other hand, the size of the enumeration tree is roughly proportional to the number of nodes in the tree. Therefore, “generate and test” is an inefficient search procedure with time complexity of 2^n where n is the number of variable in the problem.

STANDARD BACKTRACKING $P_k(v_1, \dots, v_k)$ is true for all $k < n$ iff

1. $v_i \in D_i$ for $(1 \leq i \leq k)$.
2. for all i, j ($1 \leq i < j \leq k$), $C_{ij}(v_i, v_j)$ is true.

Table A.2: Search Procedure for Standard Backtracking technique

A.2.2 Standard Backtracking

One of the simplest techniques for determining the satisfiability of a CSP is backtracking. The idea is to choose a variable, and for each value of its domain, replacing the variable with that value in the constraints and determining the satisfiability of the constraints. This process repeats until a solution is found or all the variables are reached and then returns *true* or *false* indicating whether the constraints are satisfiable. Moreover, if a dead end is reached, it will return to the previous stage and check on the other side. The procedure is listed in Table A.2.

In standard backtracking, constraints are used backward to achieve a *posteriori* pruning. Given a sequence $\langle v_1, \dots, v_k \rangle$, the problem is to extend it by finding a value v_{k+1} for x_{k+1} in such a way that all the constraints involving x_{k+1} and a variable from x_1, \dots, x_k are satisfied. If there exists no such value, the sequence $\langle v_1, \dots, v_k \rangle$ cannot be extended and there is no need to search further in this part of the tree. This *posterior* pruning enables a drastic improvement in efficiency over “generate and test”, which has to test all the assignments beginning by $\langle v_1, \dots, v_k \rangle$. However, if standard backtracking rediscovers the same fact continually, detects the failures and useless generation lately or backtracks to the first choice, it will suffer from a pathological behavior called *thrashing*.

<p>FORWARD CHECKING $P_k(v_1, \dots, v_k)$ is true for all $k < n$ iff</p> <ol style="list-style-type: none"> 1. $v_i \in D_i$ for $(1 \leq i \leq k)$. 2. for all i, j ($1 \leq i < j \leq k$), $C_{ij}(v_i, v_j)$ is true. 3. for all l ($k < l \leq n$), there exists a value v_l in D_l such that $C_{1l}(v_1, v_l), \dots, C_{kl}(v_k, v_l)$ are true.

Table A.3: Search Procedure for Forward Checking technique

A.2.3 Forward Checking

Forward checking is the easiest way to prevent future conflicts. It checks only the constraints between the current variable and the future variables. When a value is assigned to the current variable, any value in the domain of an unassigned variable, which conflicts with this assignment, is removed from the domain. The advantage of this is that if the domain of an unassigned variable becomes empty, it is known immediately that the current partial solution is inconsistent. Forward checking therefore allows branches of the search tree that will lead to failure to be pruned earlier than with simple backtracking. Note that whenever a new variable is considered, all its remaining values are guaranteed to be consistent with the past variables. So checking an assignment against the past assignments is no longer necessary.

The procedure of forward checking is listed in Table A.3. It overcomes many drawbacks in “generate and test” and backtracking. It spends more time in each node of the search tree to reduce the number of nodes considered, the set of possible values for the not-yet-assigned variables and the number of constraints checks so as to achieve an overall improvement in performance.

<p>LOOKING AHEAD $P_k(v_1, \dots, v_k)$ is true for all $k < n$ iff</p> <ol style="list-style-type: none"> 1. $v_i \in D_i$ for $(1 \leq i \leq k)$. 2. for all i, j ($1 \leq i < j \leq k$) $C_{ij}(v_i, v_j)$ is true. 3. for all l ($k < l \leq n$), there exists a value v_l in D_l such that $C_{1l}(v_1, v_l), \dots, C_{kl}(v_k, v_l)$ are true. 4. for all l ($k < l \leq n$), there exists a value v_l in D_l such that it is possible to find values $v_{k+1}, \dots, v_{l-1}, v_{l+1}, \dots, v_n$ in $D_{k+1}, \dots, D_{l-1}, D_{l+1}, \dots, D_n$ which satisfy $C_{k+1l}(v_{k+1}, v_l), \dots, C_{l-1l}(v_{l-1}, v_l), C_{l+1l}(v_{l+1}, v_l), \dots, C_{ln}(v_l, v_n)$.
--

Table A.4: Search Procedure for Looking Ahead technique

A.2.4 Looking Ahead

The techniques used in looking ahead is similiar to that of forward checking. In looking ahead, constraints are used even when more than one variable are left uninstantiated. It reduces the set of possible values that can be assigned to these variables. It prunes the variables earlier than that in forward checking. Therefore, the search size is reduced due to the smaller search space.

Looking ahead avoids much redundant work and also makes failures appear earlier in the search tree. It prevents bad backtracking points because of the directly propagated consequences of the choices to the unassigned variables. However, it is less incremental than forward checking. Indeed, looking ahead cannot remember and save most of the test results when checking the unassigned variables against the unassigned variables. Therefore, omitting these tests often results in a better efficiency.
