94 **Abstract**

95

96 HIV infection results in a state of chronic immune activation leading to premature immune aging, B-
97 cells dysfunction, that persists despite prolonged virological suppression. In this scenario,
98 adolescence living with perinatally acquired HIV (PHIV), deserve a peculiar attention since
99 potentially exposed for their entire life to chronic immune activation. Here we identified determinants
100 of precocious aging B cells in 40 PHIV undergoing suppressive antiretroviral therapy (ART) for
101 median 13.5 years. All individuals started ART by 2nd year of life and achieved virus suppression
102 within the 1st year of ART, with majority of patient maintaining suppression until analysis and 5/40
103 experiencing viral Spike (transient elevation of HIV-1 VL, 50-999 copies/ml). We employed a multi-
104 omics approach including deep immunological B and T cell phenotype in PBMC, with aging B cells
105 defined by the expression of T-bet and CD11c; plasma proteomics analysis by mass spectrometry and
106 serum level of anti-measles antibodies as correlates of humoral response. We found that individuals
107 with expansion of aging B cell, defined by the expression of T-bet+CD11c+, were those starting
108 treatment later, presenting detectable levels of cell-associated HIV-1 RNA, history of Spikes, and a
109 higher frequency of exhausted T-cells, including those expressing PD-1, LAG3, TIGIT. Accordingly,
110 the proteomic analysis revealed that subjects with expansion of aging B cells and exhausted T cells
111 had enrichment of proteins involved in immune inflammation and complement activation pathways,
112 such as CLU and APCS which are also involved in tumor progression. Signs of precocious aging
113 were associated with a reduced capacity to maintain virological memory against measles vaccination.
114 To our knowledge, this is the first study focusing on precocious B-cell aging and dysfunctionality in
115 PHIV with long-term virological suppression. Our experimental strategy enabled identification of
116 clinical, viral, cellular and plasma soluble markers associated with B-cells aging. Our results pave the
117 way to further define risk of disease progression or lymphoproliferative disorders in PHIV.

118 **Author summary**

119

120 Despite a successful antiretroviral therapy (ART), adolescence living with perinatally acquired HIV
121 (PHIV) experience B-cells dysfunction, including loss of vaccine-induced immunological memory
122 and higher risk of developing B-cells associated tumors. It is thus paramount to define novel and
123 precise correlates of precious aging B cell for the definition of novel therapeutic strategies. Here, we
124 studied 40 PHIV who started treatment by 2nd year of life and maintain virological suppression for
125 13.5 years, with 5/40 patients experiencing transient elevation of the HIV-1 load in the plasma
126 (Spike). We applied a multi-omics approach including immunological B and T cell phenotype, plasma
127 proteomics analysis and serum level of anti-measles antibodies as functional correlates of vaccine-
128 induced immunity. We found that levels of aging B cells were positively associated with age at ART
129 start, cell associated HIV-1 RNA (caHIV-1 RNA) and the presence of Spikes. Individuals with
130 increased proportions of aging B cells had concomitant expansion of exhausted T cells and were
131 unable to maintain vaccine-induced immunity over time. B-cell aging, and T-cell exhaustion were
132 also associated with proteins involved in immune inflammation. The factors found here to be
133 associated with aging B-cell could inform further therapeutic studies.

141

142 INTRODUCTION

143

144 HIV-1 replication is associated with abnormalities in all major lymphocyte populations, including the
145 B-cell compartment which results in hyperactivation and exhaustion (1-5). While early antiretroviral
146 therapy (ART)-initiation partially averts this detrimental condition (6), late ART initiation during the
147 chronic stage of HIV infection results in precocious aging of the immune system with irreversible
148 loss of memory B cells and expansion of exhausted B cell subsets including activated memory (AM),
149 double negative (DN)- and tissue-like memory B cells (TLM)(1, 4, 6, 7). The adhesion molecule
150 CD11c and the transcription factor T-bet identify a discrete B cell subset, induced by innate activation
151 and maintained by chronic inflammation or antigen stimulation, may play a detrimental role in
152 chronic HIV infection (8). Overall, chronic B cell activation observed during HIV infection has been
153 related to a reduction of functional resting memory B cells resulting in precocious waning of routine
154 vaccine-induced antibody titers (9-11) and increased risk of age-associated pathologies (12, 13),
155 including malignancies (14). Indeed, a B cell lymphoproliferative disorder such as Hodgkin's
156 Lymphoma has remained stable or even increased in HIV-positive adults since the introduction of
157 ART and is ~11-fold higher than in the HIV-negative population (15). In this context, perinatally HIV
158 infected children deserve particular attention, given their life-long exposure to chronic immune
159 activation. It remains unknown whether early ART initiation during acute HIV infection followed by
160 long-term virological suppression could prevent precocious aging of the B-cell compartment.
161 Longitudinally well characterized, adolescents living with perinatally acquired HIV-1 (PHIV) with
162 sustained and prolonged virological suppression represent a unique opportunity to investigate this
163 scientific question. Indeed, children who started ART in infancy are rarely able to achieve and
164 consistently maintain viral control for long periods. In the present work, we attempt to identify
165 determinants of B-cell activation and dysfunctionality in European PHIV who have been treated with
166 ART for >13 years and have a documented history of virus suppression. We performed deep B and

167 T cell phenotyping with a particular focus on factors associated with lymphocyte aging and extensive
168 mass spectrometry-based plasma proteomic analysis. Serum levels of anti-measles antibodies (Abs)
169 were analyzed as correlates of functional humoral immune response.

170

171 **RESULTS**

172

173 **Study cohort**

174 Patient characteristics are shown in Table 1. Overall, we analyzed 40 PHIV (males 13/40, 32.5%),
175 that started ART at a median 4.1 months (IQR 0.3-6.2), achieved virological suppression after median
176 4.69 (2.52–6.26) and were successfully on ART for median 13.5 years (8.1-16.5). We measured cell
177 associated (ca)HIV-1 DNA (caHIV-1 DNA median 48.8 copies/10⁶ PBMC), caHIV-1 RNA in the
178 Pol and LTR regions. Overall, 5/40 (13%) had experienced a Spike in HIV-1 Viral Load (HIV-1 VL
179 between 400-999 c/mL, returning to VL <50 c/ml at next blood draw) at some point in their lives
180 (Table 1, Fig.1).

anti-Measles IgG, median years from vaccination (IQR)	5 (2-8)

193

194

195 **Time of ART-start and caRNA are associated with levels of aging T-bet⁺ CD11c⁺**

196 **B cells**

197 We performed an extensive immune phenotyping focusing on the B-cell compartment (gating

198 strategy shown in Fig.1A). We found that the proportion of DN and AM expressing both T-bet and

199 CD11c were positively associated with the time of ART initiation, with expansion of T-bet⁺CD11c⁺

200 DN B cells ($p=0.03$, Fig. 1B) and T-bet⁺CD11c⁺ AM B cells ($p=0.02$, Fig.1C) in those with delayed
201 ART initiation. We further explored if the levels of aging in the B-cell compartment could be
202 associated with the HIV-reservoir. Whereas caHIV-1 DNA showed no association with any evidence
203 of aging B cell compartment, both total caHIV-1 RNA (LTR) and unspliced caHIV-1 RNA (Pol)
204 demonstrated a positive association with the aging-B cells (Fig. 1D). caHIV-1 RNA was associated
205 with B cells, AM and DN expressing T-bet⁺ alone or together with CD11c, with higher levels of these
206 B-cell populations present in individuals with detectable ongoing virus expression (Fig. 1E, 1F). We
207 further stratified the study participants by those who did (group I= 5) or did not (group II= 35)
208 experience Spikes during their lifetime (Fig. 1g). Group I had significantly higher levels of AM T-
209 bet⁺ cells compared to group II ($p=0.04$, Fig. 1g). These data showed that age at ART initiation is
210 strongly correlated with levels of B-cell aging in PHIV and that ongoing HIV-1 replication is
211 associated with precocious aging.

212

213 **Fig.1 Time of ART initiation and cell associated HIV-1 RNA (caRNA) are associated with**
214 **expansion of aging B cells.** Gating strategy is shown in a); in b) and c) correlations between aging B
215 cells and age at ART start are shown; d) correlation plot between viral correlates of recent replication
216 and aging B-cells / exhausted T-cells are shown; differential analysis between levels of aging B cells
217 and caRNA or SPIKE being detected vs non-detected is shown in e), f), g), p values are calculated
218 using Mann Whitney test. Spearman p values are shown in b), c), and d). Significance was set at
219 $p>0.05$. DN= double negative; AM= activated memory; MFI= mean fluorescent intensity.

220

221 **Individuals with expansion of aging B cells have elevated levels of exhausted T-**
222 **cells**

223 We then explored whether the levels of aging within the B-cell compartment corresponded to elevated
224 levels of exhausted T-cells. Within the aging B-cells we included T-bet⁺CD11c⁺, T-bet⁺ only B-cells,

225 or levels of T-bet (MFI) within the whole B compartment as well as within the ‘namely aging’
226 phenotypes (AM and DN). In assessing the T-cell compartment, we focused on populations
227 expressing exhaustion biomarkers (Fig. 2). Overall, correlation analysis demonstrated direct positive
228 association between B and T cells, suggesting that a certain extent of immune aging/exhaustion
229 persisted in different cellular populations, even many years after successful treatment and virological
230 control. AM T-bet⁺CD11c⁺ was associated with PD-1 expression on CD4 effector (p=0.006) and T
231 follicular helper cells (Tfh) (p=0.049) cells. Furthermore, TIGIT expression on CD4 subset and on
232 Tfh showed a strong positive association with all the aging B-cell populations (Fig. 2B). Similarly,
233 LAG3 expression on transitional memory (TTM) demonstrated a strong association with AM
234 (p=0.002) and DN (p=0.003) expressing both T-bet and CD11c. These data demonstrated that
235 premature aging and exhaustion persists simultaneously in both B and T cell compartments, even
236 after >10 years of ART.

237

238 **Fig.2 Levels of exhausted T-cells are positively associated with levels of aging B-cells.** In a) a
239 cartoon showing the main findings of the figures are pictured. In b) Heatmap plot showing Spearman
240 correlations between exhausted T-cells and levels of aging B-cells. Only significant correlations are
241 shown with red indicating positive correlations and Blue the negative ones. The colored scale going
242 between 1 and -1 indicates the rho values. DN= double negative; AM= activated memory.
243 Significance was set at p<0.05.

244

245 **Proteomic profiles associated with precocious immune aging**

246 To assess whether humoral/soluble factors might correspond to aging/exhaustion phenotypes, we
247 performed liquid chromatography/mass spectrometry-based proteomics, detecting 338 plasma
248 proteins (16). The distinct immunological, virological, and clinical features associated with immune
249 aging were correlated to the whole plasma proteomic profile (Supp. Fig 1). Two distinct clusters were
250 initially identified which were negatively (36 proteins) or positively (37 proteins) associated with

251 features of immune exhaustion (Fig. 3A). Such protein clusters were further interrogated for their
252 biological role by enrichment analysis on Reactome and Gene Ontology (GO) biological processes
253 databases (Fig. 3B). Immune inflammation and complement cascade activation pathways were
254 enriched in proteins positively associated with features of immune aging (bottom panels, Fig. 3B and
255 3C). Indeed, amyloid P component in serum (APCS) and clustering (CLU), both involved in
256 apoptotic, aging and tumor progression processes (GO:0002673) together with complement cascade
257 molecules such as C5, CFI, C4BPA, CFB (R-HSA-173623) were positively associated to selected
258 features of immune aging (Supplementary Table 1). In addition, proteins of light and heavy chain of
259 immunoglobulins, involved in humoral immune response pathway (GO:0002920) such as IGLV1-
260 47, IGHV4-34, IGLV2-23, IGHV3-48 were positively associated with immune aging. Enrichment
261 analysis performed on negatively correlated proteins, showed no association with inflammatory
262 pathways but only with processes involved in coagulation. Indeed, proteins such as APOH,
263 SERPINF2, HRG involved in pathways of negative regulation of blood coagulation (GO:0030195)
264 and platelet degranulation (R-HSA-76002) were negatively associated with features of aging
265 (Supplementary Table 1).

266

267 **Fig 3. Association between proteomic profiling and levels of aging B-cells and exhausted T-cells.**

268 A) Heatmap plot showing Spearman correlations between the 13 unfunctional features values and the
269 abundance of the 73 plasma proteins belong to the two clusters identified in correlation matrix with
270 all 338 proteins. Red indicates positive correlations and Blue negative ones. Bubble plots showing
271 the top 10 Reactome pathways (B) and GO Biological Process (C) significantly enriched (Adjusted
272 p-value < 0.05) in proteins positively (Pos) and negatively (Neg) correlated with the 13 unfunctional
273 features. The proteins were separated into positively and negatively correlated based on the two
274 clusters showed in the correlation heatmap in panel A. Colors are related at the \log_{10} adjusted p-value
275 values and the circle diameter are related at the number of proteins for each term. Significance was
276 set at $p < 0.05$.

277 **Expansion of aging B-cells is associated with B-cell dysfunctionality in PHIV**

278 We further assessed whether the presence of aging B-cells could affect the functionality of the B-cell
279 compartment to maintain immunological memory against vaccinations, such as measles.
280 Interestingly, the proportion of B-cells expressing the senescence marker T-bet, demonstrated
281 negative association with the capacity of B-cells to maintain immunological memory to measles
282 vaccination (Fig. 4A). Higher levels of CD19+CD10-T-bet+ B cells were associated with reduced
283 plasma concentrations of anti-measles specific IgG (Fig. 4B, $\rho=-0.338$, $p=0.03546$). Of note, this
284 association was strong regardless of the time of ART initiation (Fig. 4C) or timing from the last
285 booster vaccination (Fig.4D).

286

287 **Fig 4. Association between aging B-cells and anti-measles humoral response.** A) Heatmap plot
288 showing Spearman correlations between aging B-cells and anti-measles plasma IgG titers (IU/ml).
289 Red indicates positive correlations and Blue negative ones. B) Spearman correlation between
290 CD19+CD10- B-cells T-bet+ and anti-Measle plasma IgG titers, with ρ and p defining the statistical
291 significance. C) and D) Spearman correlation between anti-Measle plasma IgG titers and Age at ART
292 in m and years from measles vaccination, respectively, with ρ and p defining the statistical
293 significance. Color dots show the distribution of CD19+CD10- B-cells T-bet+. Significance was set
294 at $p<0.05$.

295

296 **DISCUSSION**

297

298 To our knowledge, ours is the first long-term follow-up study focusing on precocious B-cell
299 aging in PHIV with long-term sustained virological suppression. We defined novel cellular and
300 molecular factors associated with precocious aging in the B-cell compartment. We found that age at
301 ART initiation, HIV caRNA, levels of exhausted T-cells and specific proteomic profiles demonstrated

302 a strong and positive association with the levels of aging B-cells expressing T-bet alone or together
303 with CD11c. The expansion of precocious aging B-cells appeared to have a direct impact on the
304 ability of these patients to maintain vaccine induced immunity over time.

305 PHIV children, particularly younger ones, are immunologically distinct from adults including
306 with respect to plasticity and immune regulation, resulting in a lower immune activation state (17).
307 Since chronic immune activation and aging in treated HIV infection is probably driven by residual
308 HIV replication (18, 19), it could be hypothesized that a prompt initiation of ART early in life
309 followed by a sustained suppression of the viral replication may be able to minimize this (20). In this
310 work, we show that perinatally infected adolescents growing with HIV present higher frequency of
311 aging-B cells directly related to time of ART initiation, despite a history of continuous viral
312 suppression, documented with at least four HIV-RNA PCR tests per year for over 10 years.

313 We next explored the virological determinants of the expansion of aging B-cell populations
314 in those with PHIV. Total HIV-1 DNA did correlate with markers of B-cells aging, probably
315 reflecting the fact that the contribution of the replication-competent virus is diluted within the entire
316 integrated virus reservoir, which is mainly inactive (21). We thus further explore the markers of recent
317 virus replication. Both spliced and unspliced HIV-1 caRNA were (AB) strongly associated with levels
318 of aging B-cells. Spliced HIV-1 RNA may reflect abortive HIV-replication, with only a minor part
319 being released as virus protein or exosome-associated fragments of RNA that can still trigger immune
320 activation (22). In contrast, the unspliced HIV-1 RNA is thought to predict the replicative-competence
321 of the virus reservoirs and has been associated with virologic failure and markers of immune
322 activation in elite controllers (20, 23, 24), recently proposed as a predictive marker of viral rebound
323 (25). In our cohort, aging B-cells were not only associated with caRNA, but frequency of aging B-
324 cells was higher in those PHIV adolescents who experienced HIV spikes in absence of virologic
325 failure. The association between expansion of aging B-cell, caRNA and viral Spikes is consistent with
326 the hypothesis that precocious aging in the B cell compartment is dependent on HIV-1 replication

327 and virus particle release, which fuels chronic immune activation, exhaustion and ultimately aging
328 (26).

329 Multiple mechanisms likely underpin the association between caHIV-1 RNA and aging B-
330 cells: 1) HIV-1 particles can interact directly with B cells surface-bound via the CD21 receptor with
331 complement 3 (C3) fragment both in peripheral blood and lymph nodes of HIV-1 patients (Kardava
332 L. et al. 2018); and 2) B-cells may function as Antigen Presenting Cells (APC) taking direct contact
333 with follicular T-cells to trigger an anti-HIV-response. In case of HIV-persistence, both B and T cells
334 should experience a state of chronic immune activation resulting in expansion of signatures associated
335 with precocious aging (27, 28). Consistent with this hypothesis, our results showed that aging B-cells
336 existed simultaneously with T-cell exhaustion. T-bet+CD11c+ B-cells showed strong association
337 with T cells expressing PD-1, TIM-3 and LAG-3 which are inhibitory receptors that are found to be
338 increased on the T-cell surface as a consequence of persistent activation and described as markers of
339 cells exhaustion (29). Furthermore, T-bet+CD11c+ aging B-cells were associated with exhausted Tfh
340 in accordance with other models of chronic antigenic stimulation such as auto-immune diseases (30).
341 In fact, the excessive T-bet+CD11c+ age-associated B cells (ABCs) (31) not only to contribute to
342 the production of auto-Abs but also to promote aberrant Tfh cell differentiation and consequently
343 compromising affinity-based germinal center B-cell selection and Ab-affinity maturation in lupus
344 mouse models.

345 There are very likely other modes of soluble factor-receptor interactions which can regulate
346 B cells during HIV-1 infection and may contribute to progression to aging of B-cell compartment
347 (32). To assess this possibility, we analyzed proteomic profiles of our patients, defining at the plasma
348 level the status of immune activation and precocious aging found in B and T cell phenotype analysis.
349 Proteins positively associated with features of HIV-related immune exhaustion were mainly involved
350 in pro-inflammatory and complement activation processes. While it was previously shown that the
351 early initiation of suppressive ART over the acute phase of the infection in HIV-infected adults
352 reduced aspects of the immune activation (18, 19), we here show the persistence of bio humoral

353 correlates of exhaustion and aging in PHIV with a history of long-term viral suppression (>10 years).
354 Specifically, APCS and CLU, both involved in processes of cell apoptosis, inflammation, and
355 lymphoproliferative processes (33-35) were positively associated to caHIV-RNA, immune
356 checkpoint-inhibitors (TIGIT and PD1 on T cells) and exhausted B cells (T-bet+CD11c+ B cell
357 subsets). Accordingly, such proteins were shown to be higher in virally controlled HIV infected adult
358 experiencing a poor immune reconstitution and disease progression despite viral control (36).

359 Proteomics further showed that complement cascade activation pathway was enriched in
360 proteins positively associated with immunological aging features including CLU. As previously
361 demonstrated, the complement activation contributes to a chronic pro-inflammatory environment
362 even in well-controlled HIV infected adults (37). Whereas the activation of the complement cascade
363 during acute HIV infection is largely via activation of the classical pathway (36, 38), recent studies
364 highlight how complement factors bind IgG3 on exhausted B cell subsets (TLM) in HIV-positive
365 individuals (32, 39). In line with this evidence, our results showed a positive association of both
366 caHIV-RNA and aging B cell subsets (T-bet+CD11c+ DN and AM) with plasma complement
367 cascade proteins. Correlation analysis further revealed an association of proteins involved in
368 coagulation processes with features of immune aging. As previously shown in adults, a pro-
369 coagulative imbalance, partially resolved by ART initiation during the acute infection (18, 19) and
370 persisting over time in HIV infected adults (40), was confirmed in our cohort where a regulation of
371 fibrinolysis was negatively associated with features of aging in both T and B cell compartment.
372 Overall, plasma proteomic profiling may suggest that the persistence of complement cascade
373 perturbation, rather than inflammatory and coagulation proteins may contribute to B -cell exhaustion
374 and signs of precocious aging in long term virally controlled (>10 years) PHIV.

375 Finally, we explored if the presence of this expanded aging B-cell population could reflect an
376 impairment of the maintenance of the humoral response towards childhood vaccination, such as
377 measles immunization which should be maintained throughout life in physiological conditions. We
378 found that levels of T-bet on the global B-cell population were negatively associated with anti-

379 measles serum IgG. These data are not due to the natural Ab decay because patients were analyzed at
380 similar median years from vaccination. Our observations raise the possibility that the maintenance of
381 specific Ab titers is related to a better maturation and preservation of the memory B cell compartment
382 as a direct consequence of an early ART.

383 In conclusion, our study demonstrated for the first time the impact of a late ART start on B-
384 cell compartment is still visible despite >10 years of suppressive ART. This set of data also suggests
385 a role of T-bet and CD11c towards the definition of B-cell exhaustion in PHIV and showed that the
386 subset of T-bet expressing B cells may negatively affect the capacity of B-cell compartment to
387 maintain a vaccine-induced functional Ab response. Further studies aiming to confirm whether such
388 multi-omic signatures of aging/inflammation can inform simplified methods to stratify risk of disease
389 progression or lymphoproliferative disorders in cohorts of long-term suppressed PHIV are needed.

390

391 **Limitations of the study**

392 While our study featured multiple strengths, as with all research it also had a number of important
393 limitations, including: a) the small size of the CARMA cohort limited the power of correlation
394 analysis to detect associations; it would be interesting to expand the immunological profiling to a
395 larger cohort; b) the lack of a control group of exposed uninfected HIV individuals and potentially of
396 another group that started therapy after 2 years of age, to deeply investigate the impact of late ART
397 start; and c) the cross-sectional study design.

398

399 **Acknowledgements**

400

401 We would like to acknowledge all patients and guardians who decided to participate in the study. We
402 thank Jennifer Faudella and Giulia Neccia for her administrative assistance. We thank Nadia Iavarone
403 and Tamara Di Marco for their nursing assistance. We thank Ilaria Pepponi for her precious lab
404 management work.

425 **Financial Disclosure**

426 This study was supported by PENTA-ID Foundation (<http://penta-id.org/>), funded through an

427 independent grant by ViiV Healthcare UK. PP and SP were supported by the NIH grant

428 R01AI127347-05. Work performed at the Laboratory Sciences Core of the Miami was supported by

429 CFAR (P30AI073961) and by the following NIH Co-Funding and Participating Institutes and

430 Centres: NIAID, NCI, NICHD, NHLBI, NIDA, NIMH, NIA, NIDDK, NIGMS, FIC, and OAR. The
431 funders had no role in study design, data collection and analysis, decision to publish, or preparation
432 of the manuscript.

433 **MATERIALS AND METHODS**

434

435 **Ethics statement**

436 This is a multi-center study which include the following institutions: Bambino Gesù Children's
437 Hospital (OPBG, Rome, Italy), University of Padua (Padova, Italy), University Hospital 12 de
438 Octubre (Madrid, Spain), Hospital Gregorio Marañón (Madrid, Spain), Imperial College Healthcare
439 NHS Trust (London, UK), Great Ormond Street Hospital (London, UK), Brighton and Sussex
440 University Hospitals (Brighton, UK). Each recruiting sites received approval by local ethic
441 committees (Foster, Dominguez-Rodriguez et al. 2020). Study participants or their legal guardians
442 gave written informed consent in accordance with the Declaration of Helsinki.

443

444 **Study population**

445 The CARMA (Child and Adolescent Reservoir Measurements on early suppressive ART) cohort is
446 part of the existing EPIICAL consortium (Early treated Perinatally HIV Infected individuals:
447 Improving Children's Actual Life) (41, 42), a multi-center, multi-cohort global collaboration
448 primarily supported by PENTA foundation (Pediatric European Network for the Treatment of AIDS).
449 CARMA included 40 perinatally HIV infected children (PHIV) with following inclusion criteria: (1)
450 start of ART within the 2nd year of life; (2) ≥ 5 years of age; (3) viral suppression (< 400 copies/mL)
451 achieved in the first 12 months after initiation of ART and maintained for at least 5 years with 4
452 plasma viral load tests performed each year prior to enrolment; (4) A single viral load between 400
453 and 1000 c/mL (Spike) is permitted annually returning to less than 50 c/ml on next testing (within 3
454 months); (5) plasma viral load of < 50 HIV-1 RNA copies/ml at enrolment. Wider characteristics of

455 participants were described elsewhere (41) and relevant info provided in Table 1. CD4 counts were
456 collected at the hospital visits and vaccination history was available from patients' files.

457

458 **Samples collection**

459 Plasma samples were obtained by centrifugation of EDTA-blood at 2000xg for 10' and stored at -
460 80°C until use. Peripheral blood mononuclear cells (PBMCs) were isolated using Ficoll density
461 gradient centrifugation, resuspended in fetal bovine serum (FBS) supplemented with 10% dimethyl
462 sulfoxide (DMSO) and stored in liquid nitrogen until use.

463

464 **B and T-cell phenotypic analysis**

465 PBMCs from 40 PHIV were thawed, washed, and stained with the LIVE/DEAD fixable BV510 dead
466 cell stain kit according to manufacturer's protocol (Life Technologies, Carlsbad, CA), used to assess
467 viability: positive cells were thus excluded from the analysis as they were considered as dead. For B-
468 cell phenotype, after washing with PBS 10% FBS, cells underwent surface staining with the following
469 monoclonal antibodies (mAbs, from BD Biosciences): CD3, CD10, CD16 (BV510), CD19 (APC-
470 R700), CD21 (APC), CD27 (FITC), IgD (BV421), IgM (PE-CF594), IgG (BV605), CD11C (PC-7).
471 Finally, stained cells were resuspended in 1% paraformaldehyde (PFA) and acquired using Stained
472 cells were acquired on Cytotflex (Beckman Coulter, Brea, CA) and analysed with FlowJo v10.0.8
473 (Tree Star) software. Following surface staining fixing and permeabilization of cells (BD
474 permeabilization solution II 1x), cells were stained with an anti T-bet BV650 (04-46, BD). For T-cell
475 phenotype, LIVE/DEAD Fixable Blue Dead Cell Stain Kit from Thermo Fisher Scientific (Boston,
476 MA) was used to detect and exclude dead cells. After washing with PBS 10% FBS, cells underwent
477 surface staining with the following monoclonal antibodies as previously described (Rinaldi S. et al.
478 2021): LAG3 BV650, TIGIT PE-Cy7, CD19 Alexa Fluor 700, HLA-DR PE, CCR7 FITC, CD38
479 BV711, PD-L1 BV711, PD-1 BV421, and CD8 PerCP from BioLegend (San Diego, CA); CD3

480 BUV496, CD4 APC-Cy7, CD4 APC-H7, PD-1 BV650, CXCR5 Alexa Fluor 647, and CD27 BV480
481 from BD Biosciences (San Jose, CA); and CD45RO PE-Cy5.5 from Beckman Coulter (Fullerton,
482 CA). Finally, stained cells were resuspended in 1% paraformaldehyde (PFA) and acquired using
483 Stained cells were acquired on a BD LSRFortessa (BD Biosciences) and analysis performed using
484 FlowJo v10.0.8 (Tree Star) software. Gating strategies for B-cell phenotypes, T-bet and CD11c are
485 provided in Fig.1. Gating strategies for T-cell analysis were shown previously (28). Positive cell
486 gating was set using fluorescence minus one control. All the reagents were tested and titrated for
487 optimum concentration before usage.

488

489 **Quantitative total HIV-1 DNA assay**

490 Total HIV-1 DNA was quantified in PBMCs of 40 PHIV by real-time quantitative reverse
491 transcription PCR (qRT-PCR) as previously described (43). All measurements were done in
492 triplicates. Results are reported as copies of HIV-1 per million cells.

493

494 **Quantitative caHIV-1 RNA assay**

495 caHIV-1 RNA was quantified as described in (28). Briefly, Qiasymphony automated platform was
496 used to isolate total cellular RNA (DSP virus/pathogen mini kit (Qiagen). RNA was further processed
497 in an in-house assay using primers of previously validated assays (44, 45) to selectively amplify total
498 (LTR) and unspliced (pol) ca-HIV-1 RNA via qRT-PCR. In order to express caHIV-1 RNA copies
499 per 10^6 PBMC, the caHIV-1 RNA measurements were normalized against cellular genes TBP1 and
500 IPO8 expression.

501

502 **Plasma proteomics preparation and analysis**

503 Plasma proteomics data was produced using a High-performance liquid chromatography mass
504 spectrometry (HPLC/MS) method as previously described (16). The sample processing employed an

505 MStern blotting protocol previously developed and validated *in house* (46-49). In brief, 1 μ L of
506 plasma (~50 μ g of proteins) was mixed in 100 μ L of urea buffer. Following reduction and alkylation
507 of the cysteine side chains, an amount of 15 μ g of proteins was loaded on to a 96-well plate with a
508 polyvinylidene fluoride (PVDF) membrane at the bottom (Millipore-Sigma), which had been
509 previously activated and primed. Trypsinization of the proteins adsorbed to the membrane was
510 achieved by incubation with the protease for 2h at 37°C. Resulting tryptic peptides were eluted off
511 the membrane with 40% acetonitrile (ACN)/0.1% formic acid (FA). The peptides were subsequently
512 cleaned-up using a 96-well MACROSPIN C18 plate (TARGA, The NestGroup Inc.). The samples
513 were analysed on the same LC/MS system as the data-dependent acquisition (DDA) runs using
514 identical LC parameters (45 minutes gradient, 59 minutes total runtime). The m/z range 375–1200,
515 covering 95% of the identified peptide, was divided into 15 variable windows based on density, and
516 the following parameters were used for the subsequent DIA analysis: resolution 35000 @ m/z 200,
517 AGC target 3e6, maximum IT 120 ms, fixed first mass m/z 200, NCE 27. The DIA scans preceded
518 an MS1 Full scan with identical parameters yielding a total cycle time of 2.4s. We use a previously
519 published in house generated spectral library (16). All DIA data were directly analysed in Spectronaut
520 v12.0.20491.18 (Biognosys, Switzerland). Standard search settings were employed, which included
521 enabling dynamic peak detection, automatic precision nonlinear iRT calibration, interference
522 correction, and cross run normalization (total peak area). All results were filtered by a q-value of 0.01
523 (corresponding to an FDR of 1% on the precursor and protein levels). Otherwise default settings were
524 used.

525

526 **Anti-Measles IgG**

527 Plasma Anti-Measles IgG titres were measured using EuroImmunAnti-Morbillo ELISA (IgG) (LOT
528 E180111AE), following manufacturer's instruction. Results given as UI/L.

529

530 **Statistical analyses**

531 Between-group comparisons were performed using non-parametric U-Mann-Whitney test for
532 continuous variables or Fisher's exact test for categorical variables. Spearman correlation (ρ) was
533 used to describe the association between continuous variables. Proteins and cell populations with
534 $>70\%$ zero values or $>50\%$ missing data were omitted from heatmaps. To focus on single associations
535 (Fig. 1d, 2b and 3a) only statistically significant correlations (p -values <0.05) were shown. In other
536 cases, to highlight clustering patterns, were shown all correlations (Fig. 3a and Supp Fig. 1). The
537 chromatic scale is proportional to the Spearman correlation, using red for positive correlations ($\rho >$
538 0) and blue for negative ones ($\rho < 0$). To investigate the biological role of the proteins belonging
539 to the two clusters (Fig 3a), a pathway enrichment analysis in Reactome 2016 and GO Biological
540 Process 2021 databases was performed using the R package "enrichr" v3.0 (50). Statistical analyses
541 were performed using R (version 4.1.1) or GraphPad Prism 6.0 software (San Diego, CA).
