## Model of molecular evolution

Adaptive molecular evolution is often conceptualised as adaptive walks on rugged fitness landscapes that are driven by changes in the genome (mutations). evolution stops at a local
fitness maximum

## The problem

Once a local fitness peak is reached there are no more selectively accessible pathways by the mechanism of single nucleotides (point) mutations. Then, the evolutionary dynamics get stuck in a suboptimal peak, hindering any possibility to reach other higher peaks.

## Proposition

We introduce a simple computational model t simulate the escaping process from a local fitness inversion mutations.

| Inversion mutations operation |  |  |
| :---: | :---: | :---: |
|  Inspired by molecular biology, these genotypes are double-strained binary vectors of length $N$ |  |  |
| $x:=\left(x_{1} x_{2} \cdots x_{N-1} x_{N}\right), \quad x_{i} \in\{0,1\}$ |  |  |
| where the complementary vector is defined such that $\bar{x}_{i}=1-$ |  |  |
|  |  |  |
| We model the chromosomal-like inversion as a two step procedure.$\hat{I}=\hat{C} \cdot \hat{P}$ |  |  |
| $\begin{aligned} & \text { 1. Conjugation operation } \hat{\hat{i}:\left(x_{i}, x_{i 1}, \ldots, x_{j-1}, x_{j}\right)} \rightarrow\left(\overline{\bar{x}}_{i} \bar{x}_{i+1}, \ldots, \bar{x}_{j-1}, \bar{x}_{j}\right), \\ & \text { 2. Permutation operation: } \end{aligned}$ |  |  |
| $\hat{\mathbf{P}}:\left(x_{i}, x_{i+1}, \ldots, x_{j-1}, x_{j}\right) \rightarrow\left(x_{j}, x_{j-1}, \ldots, x_{i+1}, x_{i}\right)$ |  |  |
|  |  |  |
| Enumeration of accessible mutants |  |  |
| Examples of the number of neighbouring sequences $D$ per genotype of size $N$ (subscripts numbers are the occurrence frequencies of $D$ ). |  |  |
| $N$ | $D_{I}$ | $D_{P}$ |
| 2 | $2_{2,3}$ | 2 |
| 3 | $5_{6,7}, 7$ | 3 |
| 4 | $\mathbf{7}_{4}, \mathbf{8}_{10}, 1 \mathbf{1 3}_{2}$ See the example below | 4 |
| 5 | $13_{20}, 177_{10}, 21_{2}$ | 5 |
| 6 | $16_{30}, 17_{18}, 188_{2}, 22_{12}, 31_{2}$ | 6 |
| 7 | $25_{7}, 29_{42}, 37_{14}, 43_{2}$ | 7 |
| 8 | $21_{16}, 29_{52}, 30_{112}, 32_{2}, 34_{8}, 36_{48}, 46_{16}, 57_{2}$ | 8 |
| 9 | $39_{6}, 40_{18}, 41_{234}, 45_{162}, 52_{36}, 53_{36}, 64_{18}, 73_{2}$ | 9 |
| 10 | $45_{100}, 46_{150}, 47_{420}, 50_{2}, 52_{40}, 53_{200}, 62_{40}, 63_{50}, 777_{20}, 91_{2}$ | 10 |

The model
We simulate artificial molecular evolution of digital organisms (replicators), each of which contains a single piece of DNA. We engineer a computational method to cartoon the double stranded structure of DNA, and simulate inversion-like mutations: a permutation of the complementary strand, which are then exchanged with the main strand within the segment where the inversion occurs. We model digital genotypes made up of a binary alphabet $\{0,1\}$ In analogy with DNA primary sequence, the bits represent (artificial binary) nucleotides. We also assume that genomes are arranged in circular strings with constant number of basepairs. In an abstract sense, our model does not consider non-coding regions, mimicking the molecular evolution of some viruses and mitochondrial DNA with compact genomes and closed double-stranded DNA circles. It is important to emphasise that our computational model simulates intragenic-like mutations. We do not include recombination, so we are modelling asexual replication.
 mutants graphs are isomorphic to the Hamming graphs $H(4,2) ;(7,2)$ $\mathrm{Q}(\mathrm{N})$ (the genotype space). The lower graphs correspond to the inversion mutations cases, where we
can appreciate that the accessiblemutants graphs are not isomorphic to their respectiv
(hypercubic) spaces.

## NK rugged landscape

 As a model for rugged fitnesslandscapes, we adopt the well known
Kauffman NK model ( $N$ is the length of Kauffman NK model ( $N$ is the length of
the genome and $K$ is the "epistatic" coupling between nucleotides) The fitess per bit

NK fitness networks

Representatives instances of the NK model for $\mathrm{N}=4$ and their fitness networks in layered representation. Node colours correspond to fitness values, increasing from left to right. The shortest paths from lowest to
highest fitness genotypes are highlighted in red. The top row shows the cases for point mutations, while the bottom row corresponds to inversion mutations. The landscapes ruggedness go from single peaks $K$ $=0$, intermediate ruggedness $K=1, K=2$, and the full rugged case $K=3$.

## Summary

This work provided computational evidence that once an adaptive walk reaches a local fitness peak, then inversion mutations can redirect the evolutionary proces towards genotypes with higher fitness values. The way our model was conceived, also proves that escape from a local peak of fitness can occur in constant environments without contingencies. Our model for inversion mutations not only elucidated an escape mechanism, but have also made it possible to uncover interesting aspects about the combinatorics of inversion mutations. We have been able to contrast the isomorphism of mutational graphs for point mutations and their isomorphism with the genotype space. Finally, it was possible to verify that for a very simple model of population genetics in the strong weak mutation selection limit -with rugged landscapes simulated with the well know NK model- our adaptive walks simulations showed that when the evolutionary dynamics is driven by inversions, higher fitness values can be reached.
