15 **Abstract:** Cost-efficient and environment-friendly treatment of hydraulic fracturing effluents is of  
16 great significance for the sustainable development of shale gas exploration. We investigated the  
17 synergistic effects of plant – microbial treatment of shale-gas fracturing waste fluid. The results showed  
18 that illumination wavelength and temperature are direct drivers for microbial activity which affected  
19 the removal effects of COD<sub>Cr</sub> and BOD<sub>5</sub>, while little effects were observed for nitrogen compounds,  
20 TDS, EC, SS and microbial species and composition. Plant-microbial synergism could significantly  
21 enhance the removal of pollutants compared with removal efficiency without plant enhancement.  
22 Additionally, the relative abundance and structure of microorganisms in the hydraulic fracturing  
23 effluents greatly varied with the illumination wavelength and temperature under plant-microbial  
24 synergism. 201.24 g Water Dropwort and 435 mg/L activated sludge with illumination of 450-495 nm  
25 (blue) at 25 °C was proved as the best treatment condition for shale-gas fracturing waste fluid samples,  
26 which showed the highest removal efficiency of pollutants and the lowest algal toxicity in treated  
27 hydraulic fracturing effluents. The microbial community composition (36.73% *Flavobacteriia*, 25.01%  
28 *Gammaproteobacteria*, 18.55% *Bacteroidia*, 9.3% *Alphaproteobacteria*, 4.1% *Cytophagia* and 2.83%  
29 *Clostridia*) was also significantly different from other treatments. The results provide a potential  
30 technical solution for improved treatment of shale gas hydraulic fracturing effluents.

31 **Keywords:** Shale gas; Hydraulic fracturing effluents; Plant-microbial synergism; Aquatic ecotoxicity;  
32 Microbial community.

48 **Highlights**

49 ● Combination of 201.24 g Water Dropwort and 435 mg/L activated sludge showed best treatment  
50 efficiency.

51 ● Illumination and temperature important drivers for pollutant removal and microbial abundance.

52 ● Blue light illumination at 25 °C was best conditions for enhancing treatment of FW.

53 ● Plant-microbial synergism is proven to be an effective treatment method for FW.

Water quality improved to  
**Wastewater  
Discharge Standard**

## 91 **1. Introduction**

92 The application of horizontal drilling and hydraulic fracturing techniques has made it possible for  
93 the cost-efficient extraction of shale gas. However, shale gas production process has also caused many  
94 environmental issues (Zhang and Yang, 2015), such as the large consumption of freshwater resources  
95 (Vandecasteele et al., 2015; Chen and Carter, 2016), the adverse impacts of regional water, air, and soil  
96 quality (Vidic et al., 2013; Chen et al., 2017; Gordalla et al., 2013; Rish and Pfau, 2017; Entekin et al.,  
97 2011; Purvis et al., 2019; Vinciguerra et al., 2015), the increase of road traffic, waste management and  
98 noise impacts (Graham et al., 2015; Sun et al., 2019), and the adverse health impacts (Durant et al.,  
99 2016; Blewett et al., 2017; Casey et al., 2015; Stacy, 2017). Among these issues, water-related  
100 environmental issues in the shale gas production have aroused greater concerns. Compared to the  
101 extraction of conventional natural gas, high volumes of freshwater (1000~30,000 m<sup>3</sup>/well/year) are  
102 required during hydraulic fracturing operations of shale gas (Chen and Carter, 2016) which  
103 subsequently lead to the production of a large amount of effluents (5~70% of the injected fluid)  
104 (Vandecasteele et al., 2015). These effluents can be distinguished as two types: flowback water (FW)  
105 from the fracturing stage and produced water (PW) from the gas production stage. The pollutants in the  
106 effluents are complex and ever-changing which include a variety of toxic chemicals (such as heavy  
107 metals, salts, soluble organic/inorganic compounds, etc.) from the formation and the additives of  
108 injected fluids (Lester et al., 2015). Thus, unqualified treatment and discharge of effluents can lead to  
109 irreversible environmental pollutions and then pose a high risk to human health.

110 The cost-efficient and environment-friendly dispose of hydraulic fracturing effluents is a major  
111 challenge for shale gas sustainable development. Deep well injection and partial treatment and reuse  
112 are the available conventional measures to minimize the environmental impacts caused by the effluents

113 in the shale gas industry (Torres et al., 2016). Physical pretreatments (filtration, pH adjustment,  
114 sedimentation and degreasing/deoiling), chemical precipitation methods and biological treatments are  
115 the common partial treatment options. Physical pretreatments can effectively remove total suspended  
116 solids and reduce the salinity of the effluents, but the treatment efficiency is limited and volatile  
117 pollutants may escape into the atmosphere during the treatment (Torres et al., 2016). Desalination  
118 technologies such as membrane separation/distillation (Cho et al., 2018), forward osmosis (Coday and  
119 Cath, 2014), mechanical vapor compression (Riley et al., 2016), electrocoagulation (Sardari et al., 2018;  
120 Lobo et al., 2016), advanced oxidation (Igunnu and Chen, 2014), and hybrid membrane bio-systems  
121 (Riley et al., 2016) are usually served to process these effluents for agricultural irrigation, livestock  
122 water and landscape water-use. Chemical precipitation methods, including coagulation, sedimentation,  
123 filtration lime softening water treatment processes, sodium hydroxide alkalization, and potassium  
124 permanganate oxidation, can effectively minimize the hardness, total organic carbon (TOC) and iron  
125 concentrations of the effluents (Lester et al., 2015; Mao et al., 2018; Torres et al., 2016), but these  
126 treatments are often expensive and the addition of chemicals may bring secondary pollutions. In the  
127 biological treatments, organic matter in the effluents could be removed effectively through aerobic  
128 degradation of activated sludge or lake water microbial consortia (Kekacs et al., 2015; Lester et al.,  
129 2013; He et al., 2019), but high total dissolved solids (TDS) concentrations of the effluents usually  
130 hinder microbial activity and thus affect treatment efficiency (Mao et al., 2018; Torres et al., 2016).  
131 Therefore, high-efficient and low-cost innovative treatments are required for the reuse or discharge of  
132 hydraulic fracturing effluents.

133 Plant-microbial synergism treatment has already been considered as a good option which takes the  
134 full advantages of plant and microbes' capability and presents good potential for a low-cost solution for

135 disposing these effluents in our previous studies (He et al., 2019). In the plant-microbial synergism  
136 treatment, water dropwort and activated sludge synergism presented high treatment efficiency of COD  
137 (39.5~51.4% reduction), TN (62.9~78.0% reduction), TP (4.4~96.5% reduction), and significantly  
138 increased the Shannon-Winner index, improved microbial community structure and reduced the aquatic  
139 ecotoxicity of these effluents (He et al., 2019). However, the treatment efficiency requires further  
140 improvement. Microbial and plant biomass is a major factor affecting the treatment efficiency (Ncibi et  
141 al., 2017; Su et al., 2012). Treatment conditions such as temperature and illumination are also usually  
142 considered as important factors influencing the treatment efficiency of biological treatment.  
143 Temperature can significantly affect biological enzyme activities and metabolic rates and hence the  
144 treatment efficiency of microorganisms and plants (Çetin and Sürücü, 1990; Gillooly et al., 2001).  
145 Previous reports have indicated that temperature caused differences in microbial number and  
146 composition of activated sludge (Eikelboom, 2000). Illumination conditions can affect the treatment  
147 efficiency of the plant-microbial synergism through the effects on photosynthetic efficiency of plants  
148 (Li et al., 2010; Li et al., 2016). Blue light illumination promotes vegetative growth through strong root  
149 growth and intense photosynthesis, while red light illumination promotes stem growth, flowering and  
150 fruit production (Ma et al., 2015; Xu et al., 2012; Wu et al., 2018). In this study, effects of biological  
151 effect and environmental condition (illumination, temperature) on water dropwort-activated sludge  
152 synergism treatment of shale-gas fracturing waste fluid were investigated to identify the optimum  
153 conditions, which can provide efficient biological treatment for shale-gas fracturing waste fluid.

## 154 **2. Materials and methods**

### 155 *2.1 Fracturing waste fluid collection*

156 The fracturing waste fluid samples (FW) were collected from Well 201-H1 in Changning Shale  
157 Gas Mining Area (Sichuan, China) and transported to the laboratory under low temperature and dark  
158 conditions. All FW samples were stored in the dark at 4 °C and centrifuged for solid-liquid separation  
159 before treatments. Then the supernatant aliquot was used for the experiment.

## 160 *2.2 Plant-microbial synergism treatment*

161 Activated sludge and water dropwort were applied in the plant-microbial synergism treatment of  
162 FW samples. Activated sludge was collected from a domestic sewage treatment plant in Caidian  
163 District, Wuhan, China and subjected to overnight aeration operation before treatments. The mixed  
164 liquor suspended solids (MLSS) concentration of the activated sludge was measured following APHA  
165 Standard Methods for the Examination of Water and Wastewater (Rice et al., 2012). Water dropwort  
166 was collected from a vegetable production base in Caidian District, Wuhan, China and washed with  
167 ultrapure water before treatment. Approximate root volumes of water dropwort were considered to  
168 have the same biomass. The root volume of water dropwort was determined as the increased volume of  
169 water when the plant root was completely immersed in clean ultrapure water.

170 The effects of different biomasses of activated sludge and water dropwort, temperature and  
171 illumination on the treatment efficiency of the plant-microbial synergism treatment were explored. As  
172 shown in Table 1, different combinations of microbial MLSS concentration, plant biomass, temperature  
173 and illumination wavelength were conducted to identify the optimum conditions for the treatment of  
174 FW samples. 1 L FW was transferred into a 5 L glass container for a 12-day treatment and all the  
175 illuminations were adjusted to the same illumination intensity with different number of illumination  
176 lights in all the treatments. Each treatment was conducted in triplicate. Water quality indicators, algal

177 toxicity and microbial community diversity and structure were analyzed before and after these  
178 treatments to evaluate their treatment effects.

### 179 2.3 Water quality parameters analysis of FW

180 Nitrogen-containing compounds, organic matters and other five indicators (TDS, pH, ORP, EC,  
181 TSS) were used for evaluating the treatment effects of different treatments. TDS, pH, electrical  
182 conductivity (EC), redox potential (ORP) were measured in HACH HQ30d portable meter with  
183 corresponding IntelliCAL™ electrode, and biochemical oxygen demand (BOD<sub>5</sub>) was measured in  
184 HACH HQ30d dissolved oxygen meters through the changes in the dissolved oxygen concentration in  
185 a 5-day duration. Nitrogen compounds concentrations (NH<sub>4</sub>-N, NO<sub>2</sub>-N, NO<sub>3</sub>-N) and chemical oxygen  
186 demand (COD<sub>Cr</sub>) of FW were analyzed in the HACH DR2800 Spectrophotometer following the  
187 measuring procedures for water or wastewater analysis (HACH Company, 2007). The determination of  
188 total suspended solids (TSS) was similarly measured as MLSS following APHA Standard Methods for  
189 the Examination of Water and Wastewater (Rice et al., 2012).

### 190 2.4 Aquatic ecotoxicity determination of FW

191 Algal aquatic ecotoxicity evaluation is carried out based on OECD method: Freshwater Alga and  
192 Cyanobacteria, Growth Inhibition Test (OECD, 2011), which can effectively assess the overall and  
193 integrative environmental impact of multiple aquatic pollutants. In this study, a unicellular green algae  
194 *Scenedesmus obliquus* was used to analyze the algal aquatic ecotoxicity of FW before and after the  
195 treatments according to the influences of FW on growth and reproduction of algal within 96 h. The  
196 algal aquatic ecotoxicity were determined according to the OECD Test Guideline 201 (OECD, 2011).  
197 Briefly, algae *Scenedesmus obliquus* were first activated and pre-cultured to the exponential growth

198 phase in an algal medium described in our previous study (He et al., 2019). Then, the test and control  
199 flasks were prepared and compared for aquatic ecotoxicity determination. In the control flasks, sterile  
200 distilled water was used to prepare the algal medium and the algae in logarithmic growth was then  
201 transferred to 100 mL of prepared medium for further cultivation in a light incubator of  $20 \pm 2$  °C with  
202 an initial algal cell concentration of  $10^4$  cells/mL. The preparation of the test flasks was the same as  
203 control, using FW sample instead of distilled water (He et al., 2019). Finally, the optical density (OD)  
204 of the algae in the control and test flasks were measured at 0, 24, 48, 72, and 96 hours, respectively.  
205 The algal ecotoxicity of FW was quantified through the reduction rate of OD in the control and test  
206 flasks during the 96-h incubation. Each aquatic ecotoxicity analysis were conducted in triplicate.

#### 207 *2.5 Determination of microbial diversity and structure in FW*

208 Microbial community diversity (Shannon index and Chao1 index) and structure of FW were  
209 determined before and after treatment, based on microbial communities analyses through  
210 high-throughput sequencing method at the Chengdu Institute of Biology, Chinese Academy of Sciences.  
211 200 ml of FW sample in each treatment were 0.22 µm-filtered under aseptic condition for microbial  
212 communities collecting. Subsequently, the MO BIO Power Soil DNA Extraction Kit (MO BIO  
213 Laboratories, Carlsbad, CA, USA) was used to extract the genomic DNA of the FW sample. the purity  
214 and concentration of the extracted DNA were then separated by agarose gel electrophoresis and  
215 measured by NanoDrop Spectrophotometer. Qualified genomic DNA was used as a template,  
216 Polymerase Chain Reaction (PCR) was performed on the V4 hypervariable region of the 16S rRNA  
217 gene using specific primers 515F (5'-GTGCCAGCMGCCGCGGTAA-3') and 909R  
218 (5'-CCCCGYCAATTCMTTTRAGT-3') with a 12-nt unique barcode (Caporaso et al., 2012; Caporaso  
219 et al., 2011). Two PCR reactions were performed on each sample and the amplified products were

220 combined and then detected by 1% agarose gel electrophoresis. A SanPrep DNA gel extraction kit  
221 (Sangon Biotech, China, catalog number SK8132) was used to excise and purify the product bands, and  
222 then the concentration and quality were determined by Nanodrop. The purification amplified products  
223 were then analysed with the v2 sequencing kit (2×250 bp) through an Illumina Miseq system. QIIME  
224 Pipeline-Version 1.7.0 (<http://qiime.org/>) was used to process the obtained raw sequence data.  
225 Microbial diversity and structure in different treatments were analyzed according to the relative  
226 abundance of microorganisms based on the sequence data.

## 227 *2.6 Statistical analysis*

228 Statistical analysis was performed using SPSS 16.0, data drawing was performed using Sigmaplot  
229 14.0, Principal component analysis (PCA) and heatmap of microbial communities was analyzed based  
230 on relative abundance data of bacterial 16S rRNA gene at class level in the different treatments using  
231 Origin 2020 and TBtools, respectively.

## 232 **3. Results and Discussion**

### 233 *3.1 Water quality improvement*

#### 234 *3.1.1 Organic compounds*

235 Before water dropwort-activated sludge synergism treatment, COD<sub>Cr</sub> and BOD<sub>5</sub> concentration of  
236 FW samples were 1323 and 7.36 mg/L, respectively. COD<sub>Cr</sub> level was 2.65 times higher than the  
237 lowest effluent standard for petrochemical enterprises defined by the Integrated Wastewater Discharge  
238 Standard of China (MEP, 1996), but BOD<sub>5</sub> level did not exceed the maximum allowable emission  
239 concentration (MEP, 1996). However, the value of BOD<sub>5</sub>/COD<sub>Cr</sub> in FW samples as low as 0.0033 also

240 indicated that most of the organic compounds in FW sample such as macromolecules (surfactants,  
241 phenolics, et al.) (Lester et al., 2015) were difficult to be biodegraded and utilized.

242 The plant-microbial synergism showed more significant effects in the removal of organic  
243 pollutants than illumination and temperature conditions for treatment of FW samples. Removal of  
244 organic pollutants with COD<sub>Cr</sub> and BOD<sub>5</sub> as indicators were presented in Fig. 1 and Fig. S1.  
245 Illumination wavelength and temperature directly affected the treatment effects of COD<sub>Cr</sub> and BOD<sub>5</sub> in  
246 the FW samples. Without biological functions, the removal efficiency of COD<sub>Cr</sub> and BOD<sub>5</sub> was 47.8%  
247 and 25.4% for natural illumination at 20 °C (a1), 61.5% and 32.1% for blue light illumination at 25 °C  
248 (b1), and 22.9% and 45.7% for red light illumination at 30 °C (c1). Biotreatment has played a major  
249 role in the COD<sub>Cr</sub> and BOD<sub>5</sub> removal of FW samples. Plant-microbial synergism on BOD<sub>5</sub> removal  
250 efficiency was highly improved to 71.3~95.0%, while COD<sub>Cr</sub> removal in some treatments was lower  
251 than that without plant-microbial effects, which indicated that plant-microbial synergism presented  
252 better performance in BOD<sub>5</sub> removal than COD<sub>Cr</sub> removal. Under the effects of plant-microbial  
253 synergism, it presented a better treatment performance in COD<sub>Cr</sub> removal under natural illumination at  
254 20 °C (a2, a3, a4) and blue light illumination at 25 °C (b2, b3, b4), compared with red light illumination  
255 at 30 °C (c2, c3, c4). Previous reports have found that blue light illumination promoted the growth of  
256 plant roots and thus enhanced the treatment effects (Xu et al., 2012), but high temperatures (30 °C)  
257 might inhibit plant growth and microbial metabolism and then reduced the biotreatment (Gillooly et al.,  
258 2001). However, no significant difference was observed for BOD<sub>5</sub> removal with different illumination  
259 wavelength and temperature conditions.

260 With comprehensive comparison of the removal efficiency of COD<sub>Cr</sub> and BOD<sub>5</sub>, treatment b2  
261 showed the highest removal efficiency for COD<sub>Cr</sub> (85.6%) and BOD<sub>5</sub> (94.4%), followed by treatment

262 a2 (COD<sub>Cr</sub> and BOD<sub>5</sub> removal efficiency 71.2 % and 90.9%) and b3 (COD<sub>Cr</sub> and BOD<sub>5</sub> removal  
263 efficiency 51.6% and 90.1%). After the treatment treatments, the COD<sub>Cr</sub> and BOD<sub>5</sub> levels of the FW  
264 sample meet the effluent standard defined by the Integrated Wastewater Discharge Standard of China  
265 (MEP, 1996).

### 266 3.1.2 Nitrogenous compounds

267 NH<sub>4</sub>-N concentration in FW samples before treatments was 9.81 mg/L, which was 1.23 times  
268 higher than the emission standard of pollutants for petroleum chemistry industry defined by China  
269 Ministry of Environmental Protection (MEP, 2015). Direct discharge of untreated FW wastewater  
270 containing high concentrations of ammonia may cause eutrophication and water quality deterioration of  
271 aquatic environments, and also present harmful effects to organisms in the environments. The  
272 biotransformation of high concentration of ammonia is beneficial for the reduction of its environmental  
273 hazards. The results showed that the NH<sub>4</sub>-N levels were higher than NO<sub>2</sub>-N (0.02 mg/L) and NO<sub>3</sub>-N  
274 (1.93 mg/L) for untreated FW samples, indicating that native microbes in the FW samples had little  
275 effect on the biotransformation of these nitrogenous compounds.

276 As shown in Fig. 1 and Fig. S1, different illumination wavelength and treatment temperature  
277 conditions (treatments a1, b1, c1) didn't cause too much difference to the removal efficiency of  
278 nitrogenous compounds in FW samples. However, the plant-microbial synergism played a key role in  
279 removing the nitrogenous compounds of FW samples. Among these treatments, the treatment b2  
280 showed the highest removal efficiency respectively for NH<sub>4</sub>-N (93.1%), NO<sub>2</sub>-N (77.7%), and NO<sub>3</sub>-N  
281 (90.6%), followed by treatment b3 (with a removal efficiency of 88.7%, 33.3% and 57.9% for NH<sub>4</sub>-N,  
282 NO<sub>2</sub>-N and NO<sub>3</sub>-N) and treatment a4 (with a removal efficiency of 74.5%, 11.1% and 52.2% for  
283 NH<sub>4</sub>-N, NO<sub>2</sub>-N and NO<sub>3</sub>-N). The obtained results indicated that the increase in microbial concentration

284 was advantageous for removing nitrogen pollutants in FW samples under low treatment temperature  
285 and natural illumination, as reflected by the removal efficiency in the treatment a2, a3 and a4. However,  
286 the removal efficiency of nitrogen pollutants in FW samples didn't increase with the increase of  
287 microbial concentration under higher treatment temperature conditions (25 °C and 30 °C) with blue light  
288 and red light illuminations.

289 After plant-microbial synergism treatment, the  $\text{NH}_4\text{-N}$  level of the treated FW sample meets the  
290 effluent standard defined by the Integrated Wastewater Discharge Standard of China (MEP, 1996) and  
291 the emission standard of pollutants for petroleum chemistry industry (MEP, 2015), significantly  
292 reducing the risk of eutrophication and deterioration of water quality.

### 293 *3.1.3 Others water quality indicators*

294 Five water quality indicators including pH, oxidation-reduction potential (ORP), total dissolved  
295 solids (TDS), electrical conductivity (EC) and total suspended solids (TSS) were determined after the  
296 treatment of the plant-microbial synergism. Different treatments showed significant differences in these  
297 tested water quality parameters. Fig. 1 and Fig. S1 showed the variations of the five water quality  
298 indicators in different treatments. Compared with the untreated FW sample with a pH of 7.39, a small  
299 increase in pH (7.6~8.4) was observed for FW samples after the treatments, except for the treatments  
300 under red light illumination at 30 °C (c2, c3 and c4). The pH of treatment c1 was lower than other  
301 treatments, probably attributed to the enhancement of the ionization in the FW samples due to the  
302 influence of higher temperature and red light illumination. Treatments c2, c3 and c4 further decreased  
303 the pH of FW samples than c1, which indicated that plant-microbial synergism presented a significant  
304 removal effect on negatively charged ions in the FW samples. The increase in acidity was not suitable  
305 for the survival and activities of effective microorganisms and plants, and thus directly affected the

306 treatment effects of other pollutants in the FW samples. The ORP of the treated FW wastewater (except  
307 for the c2, c3, and c4 treatments) was higher than 0 mv indicated that the FW samples in these  
308 treatments was in an oxidizing environment which was beneficial for the growth of aerobic  
309 microorganisms thus increasing the degradation of pollutants. However, ORP of the FW samples after  
310 c2, c3, and c4 treatments was lower than 0 mv, indicating a reducing environment against the treatment  
311 of the pollutants.

312 The variation of illumination wavelength and treatment temperature showed little effect on the  
313 TDS, EC and SS removal from the FW samples, without the role of plant and microbes. Comparatively,  
314 a reduction of TDS (45.7~83.9%), EC (24.3~70.0%) and TSS (3.6~59.1%) was observed after the  
315 plant-microbial synergism treatments. Treatment b2 presented the best performance in removing TDS  
316 (83.9%) and EC (70.0%) from FW samples, followed by b3 and a3 (with a removal efficiency of 78.7%  
317 and 72.0%, respectively). However, the removal efficiency of TSS in the FW sample followed the  
318 pattern: treatment b2 > b3 > a2.

### 319 3.2 Aquatic ecotoxicity of fracturing waste fluid after treatments

320 Aquatic ecotoxicity of FW samples before and after treatments was compared based on the growth  
321 reduction and reproduction impairment of green algae *Scenedesmus obliquus* in 96h. Fig. 2a shows the  
322 algal ecotoxicity of FW samples after treated by different concentration of activated sludge. The results  
323 showed that 435, 904 and 1339 mg/L activated sludge didn't produce obvious difference on the algal  
324 growth and reproduction inhibition rate of in a 96-h exposure, compared with the untreated FW  
325 samples. The algal growth and reproduction were almost completely inhibited in the FW samples after  
326 treated by different concentration of activated sludge.

327 As shown in the impacts of treated FW samples on the algal growth and reproduction curves (Fig.  
328 2b), the treated FW samples still presented high inhibition effects on the algal growth and reproduction,  
329 except for the treatment b2. The ecotoxicity of FW sample was significantly reduced after b2 treatment,  
330 in which the growth and reproduction inhibition rate at 48, 72 and 96-h were 5.56%, 4.94% and  
331 12.42%, respectively. Compared with the healthy algae in the control, the treated FW sample had a  
332 very small negative impacts on the growth and reproduction of these algae, showing a good treatment  
333 effects on the removal of pollutants in FW samples which was consistent with the results of the water  
334 quality indicators. However, the 96-hour algal growth and production inhibition rate of the treated FW  
335 samples in other treatments was ranged from 87.58% to 100%, which was still showing a high algal  
336 ecotoxicity.

### 337 *3.3 Changes in the microbial community diversity and structure of FW*

#### 338 *3.3.1 Variations of Microbial community diversity*

339 Biodiversity indicators refers to the richness and uniformity of the organisms in a specific  
340 ecosystem. In this study, two alpha diversity indices (Shannon Index and Chao1 Index) were calculated  
341 to evaluate the variations of microbial community diversity and richness of FW samples after different  
342 treatments (Fig. 3). Before the treatments, the Shannon index and Chao 1 index significantly increased  
343 after the addition of 435, 904, 1339 mg/L activated sludge into FW in the treatments N2, N3, N4,  
344 compared to the untreated FW samples (treatment N1). The increases of the diversity and richness of  
345 the microbial community indicated that the addition of activated sludge provided a large amount of  
346 exogenic microorganisms into the plant-microbe synergism treatment system. After a 12-days treatment,  
347 the microbial species and populations showed a significant response to the changes in temperature,

348 illumination wavelength, addition of plants and then reached a new balance, as reflected by the  
349 decrease of the Shannon index and Chao1 index (compared to the treatments N1, N2, N3, N4) in  
350 different treatments.

351 As shown in Fig. 3, no significant difference was observed for the Shannon Index in the FW after  
352 treatments from the untreated FW samples. The Shannon Index of FW in some treatments was even  
353 lower than the untreated FW samples. However, the Chao1 Index showed significant difference  
354 between the treated and untreated FW samples. Compared to untreated FW samples, the Chao1 index  
355 in FW were significantly enhanced from 878.11 to 2115.77 after 12 days of plant-microbial synergism  
356 treatment, except the treatment b1 (with a Chao1 Index of 616.08). The low Chao1 Index in treatment  
357 b2 was consistent with the results of water quality improvement and algal ecotoxicity as describe  
358 before. Higher Chao1 Index of FW samples in treatment c2, c3 and c4 indicated that the  
359 plant-microbial synergism in red light illumination at 30 °C was beneficial for the microbial growth and  
360 reproduction so that the richness and biodiversity of the microbial community was highly improved.  
361 However, our results of water quality improvement and algae ecotoxicological effects showed that the  
362 highest biodiversity index was not observed in the treatment b2 which presented the best treatment  
363 performance in FW samples. Thus it can be seen that microbial community diversity and abundance  
364 were not the unique determinants for the treatment efficiency of FW samples. The microbial species  
365 and composition were also very important for the plant-microbial synergism treatment of FW samples,  
366 which has been reported in previous studies (He et al., 2019).

### 367 *3.3.2 Species and composition of microbial community*

368 Taxonomic composition distribution histograms and heatmap in each treatment were shown in Fig.  
369 4 and Fig. S2, based on the relative abundance of the microbial community at the class level.

370 *Alphaproteobacteria* (45.61%), *Gammaproteobacteria* (23.35%), *Flavobacteriia* (16.89%) and  
371 *Anaerolineae* (5.41%) were the dominant microbial species, followed by *Betaproteobacteria* (2.52%),  
372 *Methanomicrobia* (1.27%), *Bacteroidia* (1.09%) and *Clostridia* (1.02%) in the untreated FW sample  
373 (treatment N1). The microbial species and composition did not change in the FW sample, however, the  
374 proportion and structure of the microorganisms greatly changed with the illumination wavelength and  
375 temperature (treatments a1, b1, c1). As shown in Fig. 4, *Gammaproteobacteria* was the most dominant  
376 species, followed by *Alphaproteobacteria*, *Flavobacteriia*, *Anaerolineae*, *Bacteroidia*.

377 After the addition of activated sludge (treatments N2, N3, N4), a large amount of new  
378 microorganisms such as *Cytophagia*, *Nitrospira*, *Acidimicrobiia*, *Anaerolineae*, *Saprospirae*, *Mollicutes*,  
379 *Gemm-1*, *Sphingobacteriia*, *Planctomycetia*, *Thermoleophilia* and *Deltaproteobacteria* were  
380 introduced into the FW samples to make the microbial community structure in the treatments complex  
381 and abundant. With the treatment of the plant-microbial synergism, the relative abundance of microbes  
382 such as *Bacteroidia*, *Flavobacteriia*, *Gammaproteobacteria*, *Alphaproteobacteria*, *Cytophagia* and  
383 *Clostridia* greatly changed (treatments a2, a3, a4, b2, b3, b4, c2, c3, c4). Microbial species and  
384 composition in the treatments c2, c3 and c4 were different from other treatments. *Bacteroidia* was  
385 found to be the main microbe in the treatments c2, c3 and c4, followed by *Gammaproteobacteria*,  
386 *Alphaproteobacteria*, *Clostridia*. *Bacteroidia* (phylum: *Bacteroidetes*) and *Clostridia* (phylum:  
387 *Firmicutes*) were found to be good at survival strategies such as producing endospores, using oxygen,  
388 and using toxic halogenated organics as electron acceptors, tolerating high temperatures, and using  
389 light for photosynthesis to live in the condition of red light illumination at 30 °C (Mor and Kwon, 2015).  
390 In contrast, a higher relative abundance of *Flavobacteriia* and *Gammaproteobacteria* but a lower  
391 abundance of *Anaerolineae* and *Bacteroidia* were found in the treatments a2, a3, a4, b2, b3 and b4.

392 *Flavobacteriia* had a potential intracellular circulation of the glycogen/starch pathway (Liu et al., 2019),  
393 which may serve as a survival strategy for starvation in FW samples. The presence of abundant toxin  
394 exporting, transcription and signal transduction related genes in *Flavobacteriia* also may further help to  
395 survive in the extreme conditions of FW (Liu et al., 2019). In addition, *Flavobacteriia* and  
396 *Gammaproteobacteria* can produce diverse carbohydrate-active hydrolytic enzymes with a good  
397 removal efficiency of organic pollutants (Martin et al., 2016), which might be the primary reason for  
398 the good performance in water quality treatment of FW samples in these treatments. High abundance of  
399 *Flavobacteriia* (36.73%) and moderate abundance of *Bacteroidia* (18.55%), *Gammaproteobacteria*  
400 (25.01%), *Alphaproteobacteria* (9.30%), *cytophagia* (4.10%) and *Clostridia* (2.83%) were observed in  
401 the FW sample after the treatment b2 with the best treatment performance (Fig. 4 and Fig. S2). The  
402 relative abundance of *Flavobacteriia*, *Bacteroidia*, *Gammaproteobacteria* and *Clostridia* were  
403 significantly enhanced compared to the untreated FW samples, supporting that these native  
404 microorganisms in the FW sample rather than the exogenic microorganisms from the activated sludge  
405 were positively activated and played an important treatment effects on the FW sample after the  
406 treatment b2.

407 A principal component analysis (PCA) was conducted to the microbial community in FW under  
408 different treatments (Fig. 5). The analysis results showed that the microbial community composition of  
409 FW in the treatment a1 and b1 showed significant difference with the untreated FW samples (N1),  
410 indicating that the influence of natural light and blue light illuminations at lower temperature (20 °C and  
411 25 °C) on the microbial community composition of FW was greater than red light illumination at 30 °C.  
412 In addition, the plant-microbe synergistic treatments (a2, a3, a4, b2, b3, b4, c2, c3, c4) remarkably  
413 changed the microbial community composition of FW samples.

414 Our previous study has reported that the microbial community composition was closely associated  
415 with its treatment efficiency of shale-gas fracturing flowback and produced water (He et al., 2019). In  
416 this study, treatment b2 showed the best performance in improving the water quality and reducing the  
417 ecotoxicity of FW samples. The composition of the microbial community in the treatment b2  
418 significantly differed from other plant-microbe synergistic treatments. *Flavobacteriia* (36.73%) and  
419 *Gammaproteobacteria* (25.01%) were the dominant microbial species, followed by *Bacteroidia*  
420 (18.55%), *Alphaproteobacteria* (9.3%), *Cytophagia* (4.1%), *Clostridia* (2.83%). As shown in the PCA  
421 analysis, *Bacteroidetes* (*Flavobacteria*, *Cytophagia*), *Proteobacteria* (*Alphaproteobacteria*,  
422 *Gammaproteobacterial*, *Deltaproteobacteria*), *Cyanobacteria* (*Chloroplast*), *Firmicutes*  
423 (*Erysipelotrichi*), and *Verrucomicrobia* (*Opitutae*, *Verrucomicrobiae*) were the dominant  
424 microorganisms which might be directly associated with the treatment efficiency of treatment b2.  
425 These microbes can first survive by their adapting and surviving strategies in FW and then play  
426 treatment effects on FW through their high decomposition and degradation abilities of pollutants. For  
427 example, *Flavobacteriia* can produce diverse carbohydrate-active hydrolytic enzymes with original  
428 biochemistry to remove organic matters; *Proteobacteria* (*Alphaproteobacteria*, *Gammaproteobacteria*,  
429 *etc.*) was also identified as significant contribution in the fixation and degradation of contaminants due  
430 to their diverse metabolic properties and wide variety in metabolism types; *Actinobacteria* could play a  
431 good synergistic effect with plants, living symbiotically with plants whose roots fixed nitrogen for  
432 plants in exchange for access to some of the plant's saccharides, which act as fungi to decompose  
433 organic matter so that the pollutant molecules can be taken up anew by plants (Servin et al., 2008).

#### 434 **4 Conclusions**

435 The treated FW samples could all meet the Integrated Wastewater Discharge Standard of China  
436 and the discharge standard of pollutants for petroleum chemistry industry. Illumination wavelength and  
437 temperature are direct drivers for the microbial treatment effects of COD<sub>Cr</sub> and BOD<sub>5</sub> in the FW  
438 samples, but showed little effect on the TDS, EC and TSS and nitrogenous compounds removal from  
439 the FW samples. With the plant-microbial synergism, enhanced effects in the removal of FW pollutants  
440 were observed. The best treatment solution for FW samples is 435 mg/L activated sludge enhanced by  
441 201.24 g Water Dropwort under blue illumination of 450-495 nm at 25 °C.

442 The relative abundance of microbes and the composition of the microorganisms greatly varied  
443 with the illumination wavelength and temperature under plant-microbial synergism, and the relative  
444 abundance were significantly enhanced under the water dropwort enhanced treatment which indicates  
445 positive effects in promoting the microbial activities.

Notes: n0, untreated FW samples; a1, a2, a3, a4, b1, b2, b3, b4, c1, c2, c3, c4, FW samples after treated by the treatments as describe in table 1.

**Fig. 1** Variations of BOD<sub>5</sub>, NH<sub>4</sub>-N, NO<sub>3</sub>-N and TDS levels in different treatments (fig.1a: BOD<sub>5</sub>; fig.1b: NH<sub>4</sub>-N; fig.1c: TDS; fig.1d: NO<sub>3</sub>-N)

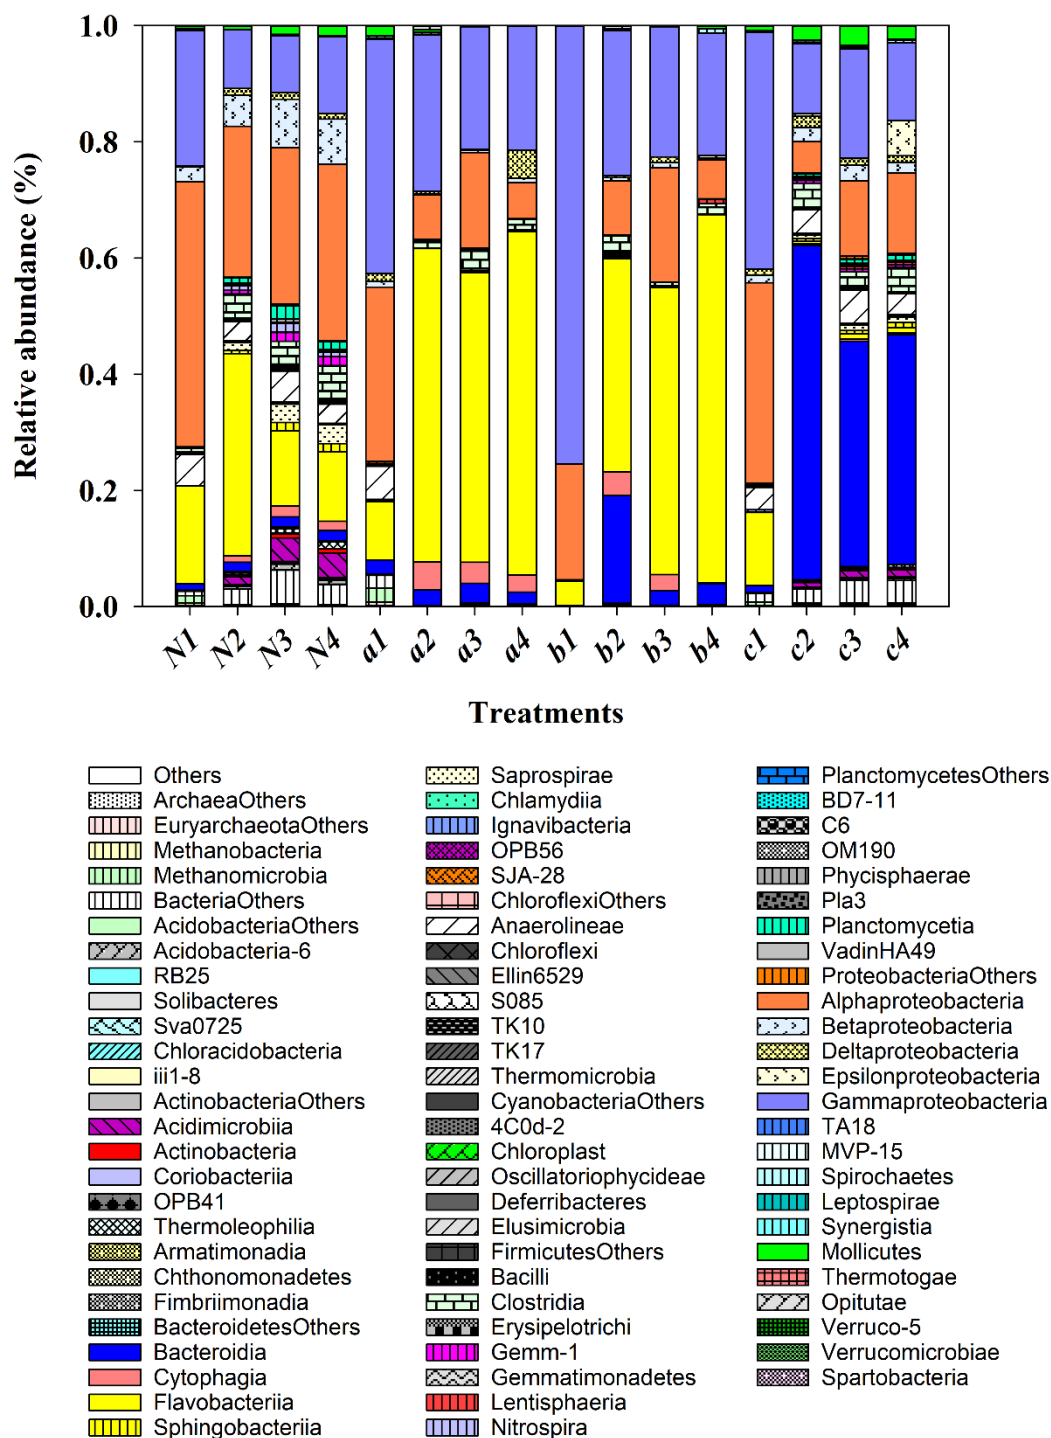

Notes: N1, untreated FW sample; N2, untreated FW added with a microbial concentration of 435 mg/L; N3, untreated FW added with a microbial concentration of 904 mg/L; N4, untreated FW added with a microbial concentration of 1339 mg/L; a1, a2, a3, a4, b1, b2, b3, b4, c1, c2, c3, c4, FW samples after treated by the treatments as describe in table 1.

**Fig. 2** Algal ecotoxicity of FW samples in different treatments (fig.2a: FW samples after treated by different concentration of activated sludge; fig.2b: FW samples after treated by various Plant-microbial synergism treatments)

**Fig. 3** Variations of microbial community diversity of FW in different treatments (fig.3a: Shannon Index of FW samples after treated by different treatments; fig.3b: Chao1 Index of FW samples after treated by different treatments)

**Fig. 4** Relative abundance of microbial community of FW under different treatments in class level

Notes: The class level number corresponds to the following: 1, others; 2, Cytophagia; 3, Flavobacteriia; 4, CyanobacteriaOthers (Classes other than 4C0d-2, Chloroplast and Oscillatoriophycideae in Cyanobacteria); 5, Chloroplast; 6, Erysipelotrichi; 7, Opitutae; 8, Verrucomicrobiae; 9, Deltaproteobacteria; 10, EuryarchaeotaOthers (Classes other than Methanobacteria, and Methanomicrobia in Euryarchaeota); 11, Methanomicrobia; 12, Lentisphaeria; 13, Gammaproteobacteria; 14, MVP-15; 15, Spirochaetes; 16, Thermotogae; 17, ArchaeaOthers (Archaea except Euryarchaeota); 18, Methanobacteria; 19, BacteriaOthers (Bacteria other than those listed in Gemmatimonadetes, Acidobacteria, Firmicutes, etc.); 20, Chloracidobacteria; 21, Coriobacteriia; 22, OPB41; 23, BacteroidetesOthers (Classes other than Bacteroidia, Cytophagia, Flavobacteriia, Sphingobacteriia, and Saprospirae in Bacteroidetes); 24, Bacteroidia; 25, Ignavibacteria; 26, OPB56; 27, ChloroflexiOthers (Classes other than Anaerolineae, Chloroflexi, Ellin6529, S085, TK10, TK17 and Thermomicrobia in Chloroflexi); 28, Anaerolineae; 29, Deferribacteres; 30, Bacilli; 31, ProteobacteriaOthers (Classes other than Alphaproteobacteria, Betaproteobacteria, Deltaproteobacteria, Epsilonproteobacteria, Gammaproteobacteria and TA18 in Proteobacteria); 32, Alphaproteobacteria; 33, Epsilonproteobacteria; 34, Synergistia; 35, Mollicutes; 36, AcidobacteriaOthers (Classes other than Acidobacteria-6, RB25, Solibacteres, Sva0725, Chloracidobacteria, and iii1-8 in Acidobacteria); 37, Acidobacteria-6; 38, RB25; 39, Solibacteres; 40, Sva0725; 41, iii1-8; 42, ActinobacteriaOthers (Classes other than Acidimicrobiia, Actinobacteria, Coriobacteriia, OPB41 and Thermoleophilia in Actinobacteria); 43, Acidimicrobiia; 44, Actinobacteria; 45, Thermoleophilia; 46, Armatimonadia; 47, Chthonomonadetes; 48, Fimbriimonadia; 49, Sphingobacteriia; 50, Saprospirae; 51, Chlamydiia; 52, SJA-28; 53, Chloroflexi; 54, Ellin6529; 55, S085; 56, TK10; 57, TK17; 58, Thermomicrobia; 59, 4C0d-2; 60, Oscillatoriophycideae; 61, Elusimicrobia; 62, FirmicutesOther (Classes other than Bacilli, Clostridia and Erysipelotrichi in Firmicutes); 63, Clostridia; 64, Gemm-1; 65, Gemmatimonadetes; 66, Nitrospira; 67, PlanctomycetesOther (Classes other than Phycisphaerae, Planctomycetia, vadinHA49, Pla3, BD7-11, C6 and OM190 in Planctomycetes); 68, BD7-11; 69, C6; 70, OM190; 71, Phycisphaerae; 72, Pla3; 73, Planctomycetia; 74, VadinHA49; 75, Betaproteobacteria; 76, TA18; 77, Leptospirae; 78, Verruco-5; 79, Spartobacteria.

**Fig. 5** Principal component analysis (PCA) of microbial community in FW under different treatment

**Table 1** Restoration condition design of twelve treatments for fracturing waste fluid

Treatment	MLSS concentration of activated sludge (mg/L)	Illumination wavelength (nm)	Temperature (°C)	Biomass of Water Dropwort (g)
a1	0	380-750 (natural)	20	0
b1	0	450-495 (blue)	25	0
c1	0	620-750 (red)	30	0
a2	435	380-750 (natural)	20	150.49
b2	435	450-495 (blue)	25	201.24
c2	435	620-750 (red)	30	108.82
a3	904	380-750 (natural)	20	200.54
b3	904	450-495 (blue)	25	108.36
c3	904	620-750 (red)	30	150.67
a4	1339	380-750 (natural)	20	108.44
b4	1339	450-495 (blue)	25	150.57
c4	1339	620-750 (red)	30	200.17
