Jet-like flows are ubiquitous in the atmosphere and oceans, and thus a thorough investigation of their behaviour in rotating systems is fundamental. Nevertheless, how they are affected by vegetation or, generally speaking, by obstructions is a crucial aspect which has been poorly investigated up to now. The aim of the present paper is to propose an analytical model developed for jet-like flows in the presence of both obstructions and the Coriolis force. In this investigation the jet-like flow is assumed homogeneous, turbulent and quasi-geostrophic, and with the same density as the surrounding fluid. Laws of momentum deficit, length scales, velocity scales and jet centreline are analytically deduced. These analytical solutions are compared with some experimental data obtained using the Coriolis rotating platform at LEGI-Grenoble (France), showing a good agreement.

Key words: jets, coastal engineering

1. Introduction

Jet-like flows dominate many environmental frameworks including large river mouths flowing into the ocean, nuclear plant discharges and even chimney smokes. Jets have been extensively studied in the simpler context of unobstructed flows in non-rotating systems (Smith & Mungal 1998). These studies revealed the influence of the initial jet characteristics (e.g. nozzle shape, dimensions, flow rate and boundary conditions such as topography and bathymetry) and hydrodynamic features of the ambient current on the jet evolution. The co-flow and cross-flow release of jets were thoroughly examined as well (Antonia & Bilger 1973; Mahesh 2013), while comprehensive reviews are provided by

Rajaratnam (1976) and Fischer *et al.* (1979). Recently, jets interacting with waves have also been analysed (Barile *et al.* 2020).

Unobstructed jets affected by background rotation have been investigated in pioneering work by Gadgil (1971). The assumption was that the jet was laminar and quasi-geostrophic. Other studies, also assuming quasi-geostrophic jets, focused both on momentum jets (Lin & Atkinson 1999) and on density-driven jets (Thomas & Linden 2007). The former study found that rotation changes the orientation of turbulent eddies, affecting the energy cascading process; the latter found that mixing and entrainment depend on bottom slope, Froude and Reynolds numbers.

More recently, Mossa & De Serio (2016) and Mossa *et al.* (2017) examined momentum jets travelling through a vegetation canopy. They analysed the turbulent integral length scales, turbulent diffusion coefficients and advective terms in the streamwise and spanwise directions for a turbulent jet entering an obstructed flow, and compared the results with those of the same jet in the absence of vegetation. In particular, the mimicked vegetation, arranged as a regular array of emergent rigid cylinders, induced an increased spanwise dispersion of the jet, acting as a blockage, and reduced at the same time the streamwise one. This finding is relevant, because it can be extended to unconventional ideas of jets through porous obstructions, such as the case of outflows from various sources spreading among oyster farms, wind farms and solar plants as well as aerial pesticides sprayed onto orchards or river jets flowing at mouths through bar deposits (Fagherazzi *et al.* 2015).

Based on previous considerations, it is clear that there is quite a good understanding of turbulent jets interacting with rotating frames and with vegetation in isolation. The mutual interaction of jet-like flows with obstructions (or macroroughness) and the Coriolis force remains inadequately investigated. It deserves a thorough understanding, especially

Figure 2. NASA Earth Observatory image by Jesse Allen and Robert Simmon, using Landsat data from the US Geological Survey, showing the offshore wind farm called London Array. (a) The offshore wind farm located in the Thames estuary (the stem array is in the rectangular zone). (b) Enlargement of the stem array of the wind farm.

considering that while density difference influences jet dynamics, for sufficiently large discharges (such as estuaries along the Atlantic Ocean coasts or in the Baltic Sea) the dynamics is mainly influenced by the inertial terms and rotation. Moreover, a further element influencing the spreading of jets is the presence of vegetation or, more generally, of obstructions in the form of macroroughness. As an example, figure 1 shows the Mississippi

flood of 2018 with an evident sediment plume spilling into the Gulf of Mexico. It is also well known that vegetation is not just a static element of marine and fluvial ecosystems, but it interacts with different processes at different scales, e.g. blade scale, patch scale or canopy scale (Albayrak *et al.* 2011). Seagrasses form the foundation of many food webs and vegetation promotes biodiversity by creating different habitats with spatial heterogeneity in stream velocity (Kemp, Harper & Crosa 2000). Marshes and mangroves reduce coastal erosion by damping waves and storm surges (Marois & Mitsch 2015). These services are all influenced in some way by the flow field existing within and around the vegetated region. At the same time, vegetation itself affects flow structure and turbulence, which in turn impact the transport of sediments and scalars (White & Nepf 2003, 2007, 2008; Tanino & Nepf 2008; Nikora, Nikora & O'Donoghue 2013). This type of interaction between flows and obstacles is also present at larger scales, such as in the case of the towers in wind farms. In this respect, figure 2(a) shows the world's largest offshore wind farm, located in the Thames estuary, where the River Thames meets the North Sea. This is the so-called London Array (figure 2b).

The present study aims at investigating the structure of a jet-like flow in a rotating system in the presence of obstacles. This study is of interest for environmental fluid mechanics, as well as for industrial applications, such as flows in mixers or rotating machinery. The jet-like flow is assumed planar, unbounded, turbulent and quasi-geostrophic, with the same density and temperature as the fluid environment where it is issued, and is characterized by a cross-length scale much smaller than the longitudinal one (Rajaratnam 1976; Jirka 1994).

The outline of the paper is the following. The theoretical model of a jet-like flow in a rotating system in the presence of obstacles is firstly illustrated. It focuses on length and velocity scales of the jets and their centre pathline, and on development of momentum deficit. The model is validated by comparing the theoretical results with those of experimental tests conducted at the Coriolis rotating platform (LEGI, France).

2. Theoretical model

2.1. Formulation of the problem

We consider an unbounded, plane and turbulent jet (Giger, Dracos & Jirka 1991; Jirka 1994), released in an ambient flow with the same temperature, salinity and density, with the presence of obstructions and a background rotation Ω . It is appropriate to specify that, assuming λ the latitude and ω the rotation rate of the Earth, the Coriolis parameter is given by $2\omega \sin \lambda = 2\Omega$. The top and bottom boundaries being assumed far from the jet, conventional Ekman theory is neglected. The origin of the coordinate system is at the centre of the jet release nozzle, the x axis is the curvilinear axis coinciding with the jet main axis, the y axis is normal to the x axis (oriented in the direction opposed to that of jet radius of curvature r) and the z axis is vertical and parallel to the rotation axis (as depicted in figure 3).

In the case of a plane turbulent jet issuing into an ambient fluid at rest with the presence of the Coriolis force and a cylinder array (figure 3), the Reynolds equations of motions are

$$\begin{aligned} & \frac{\partial u}{\partial t} + u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} + w \frac{\partial u}{\partial z} - 2\Omega v \\ & = -\frac{1}{\rho} \frac{\partial p}{\partial x} + \nu \left(\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2} \right) - \left(\frac{\overline{\partial u'^2}}{\partial x} + \frac{\overline{\partial u'v'}}{\partial y} + \frac{\overline{\partial u'w'}}{\partial z} \right) - \frac{1}{\rho} D_x, \end{aligned} \quad (2.1)$$

Figure 3. Sketch of a plane jet. (a) Plan view of the jet with a clockwise rotation. (b) Typical velocity profiles at the nozzle exit (on the left) and in the zone of established flow (on the right).

$$\begin{aligned} \frac{\partial v}{\partial t} + \frac{U_b^2}{r} + u \frac{\partial v}{\partial x} + v \frac{\partial v}{\partial y} + w \frac{\partial v}{\partial z} + 2\Omega u \\ = -\frac{1}{\rho} \frac{\partial p}{\partial y} + \nu \left(\frac{\partial^2 v}{\partial x^2} + \frac{\partial^2 v}{\partial y^2} + \frac{\partial^2 v}{\partial z^2} \right) - \left(\frac{\partial \overline{u'v'}}{\partial x} + \frac{\partial \overline{v'^2}}{\partial y} + \frac{\partial \overline{v'w'}}{\partial z} \right) - \frac{1}{\rho} D_y, \end{aligned} \quad (2.2)$$

$$\begin{aligned} \frac{\partial w}{\partial t} + u \frac{\partial w}{\partial x} + v \frac{\partial w}{\partial y} + w \frac{\partial w}{\partial z} \\ = -\frac{1}{\rho} \frac{\partial p}{\partial z} + \nu \left(\frac{\partial^2 w}{\partial x^2} + \frac{\partial^2 w}{\partial y^2} + \frac{\partial^2 w}{\partial z^2} \right) - \left(\frac{\partial \overline{u'w'}}{\partial x} + \frac{\partial \overline{v'w'}}{\partial y} + \frac{\partial \overline{w'^2}}{\partial z} \right) - \frac{1}{\rho} D_z, \end{aligned} \quad (2.3)$$

where u , v and w and u' , v' and w' are the time-averaged and fluctuating velocity components in the x , y and z directions, respectively, p is the time-averaged pressure at any point, ν is the kinematic viscosity and ρ is the mass density of both the jet and ambient fluid. The centripetal acceleration is U_b^2/r , with U_b being the average of the longitudinal velocity in each cross-section. Furthermore, the drag forces in the x , y and z directions, i.e. the resistance due to the solid medium, sum of form and viscous drag over the stem, are D_x , D_y and D_z , respectively; t is the time variable and the overbar represents a time-average operator.

The continuity equation is

$$\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} + \frac{\partial w}{\partial z} = 0. \quad (2.4)$$

The relevant dimensionless parameters of the analysed flow are the Rossby number R_o and the Reynolds number R_e , defined as

$$R_o = \frac{U_0}{\Omega L_x}, \quad R_e = \frac{U_0 b_0}{\nu}, \quad (2.5a,b)$$

where L_x is the jet-like longitudinal length scale and U_0 is the velocity at the jet nozzle (figure 3b).

It is worth noting that atmospheric and oceanographic flows can be considered as shallow with horizontal length scales much larger than their vertical length scales. Therefore they could be described using the shallow water equations. The Rossby number, which characterizes the strength of inertia compared to the strength of the Coriolis force, is equal to zero or is very small in the case of a geostrophic flow. In our quasi-geostrophic jet-like flow, the Rossby number is of order 1, so that the Coriolis and inertial forces are of similar magnitude. Below we consider only the zone of established flow (at $x > x_0$), where the longitudinal velocity distribution in each cross-section, i.e. the distribution of the u -velocity in the radial direction, has the same well-known Gaussian shape shown in figure 3 (Pope 2000). As shown in figure 3(b), at each cross-section the maximum longitudinal velocity component is u_m and b is the typical length scale, which is generally assumed as the distance from the jet centreline where the longitudinal velocity is $u = u_m/e$, with e being the Euler number, whose value is equal to b_0 at the jet origin. In the present model we consider the case of unbounded plane jets issuing into an ambient flow with a regular square array of emergent cylinders of uniform diameter d and distance s (figure 4). Another key parameter of the cylinder array used in the present paper is the frontal area per unit volume of the obstructions $a = nd$, which is equal to d/s^2 in the case of a periodic square array, where n is the number of elements per unit planar area (Nepf 1999). The local variations of the velocity profiles detected in flows with obstacles (Ben Meftah & Mossa 2016) are not considered here. However, the envelope cross-section velocity profile is taken into account to evaluate the effects of the presence of obstacles on the entire velocity profile.

The effect of obstructions is considered using the drag coefficient C_D in the drag terms. As shown by Nepf (1999), various resistance laws of drag for flow in porous media can be derived. Particularly, in obstructed free-surface flows, the following quadratic form can be assumed:

$$D_i = \frac{1}{2} \rho C_D a |u_i| u_i, \quad (2.6)$$

with $i = x, y, z$ (Kaimal & Finnigan 1994). Since the flow is quasi-two-dimensional, we can approximate that $w = 0$, $\partial/\partial z = 0$, $\overline{u'w'} = 0$ and $\overline{v'w'} = 0$, and consider the mean flow as steady, $\partial/\partial t = 0$. Furthermore, u is generally much larger than v in a large portion of the jet and velocity and stress gradients in the y direction are much larger. Therefore, (2.1) and (2.2) become

$$u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} - 2\Omega v = -\frac{1}{\rho} \frac{\partial p}{\partial x} + v \frac{\partial^2 u}{\partial y^2} - \frac{\partial \overline{u'^2}}{\partial x} - \frac{\partial \overline{u'v'}}{\partial y} - \frac{1}{\rho} D_x, \quad (2.7)$$

$$0 = -\frac{1}{\rho} \frac{\partial p}{\partial y} - \frac{\partial \overline{v'^2}}{\partial y} - \frac{1}{\rho} D_y - 2\Omega u - \frac{U_b^2}{r}. \quad (2.8)$$

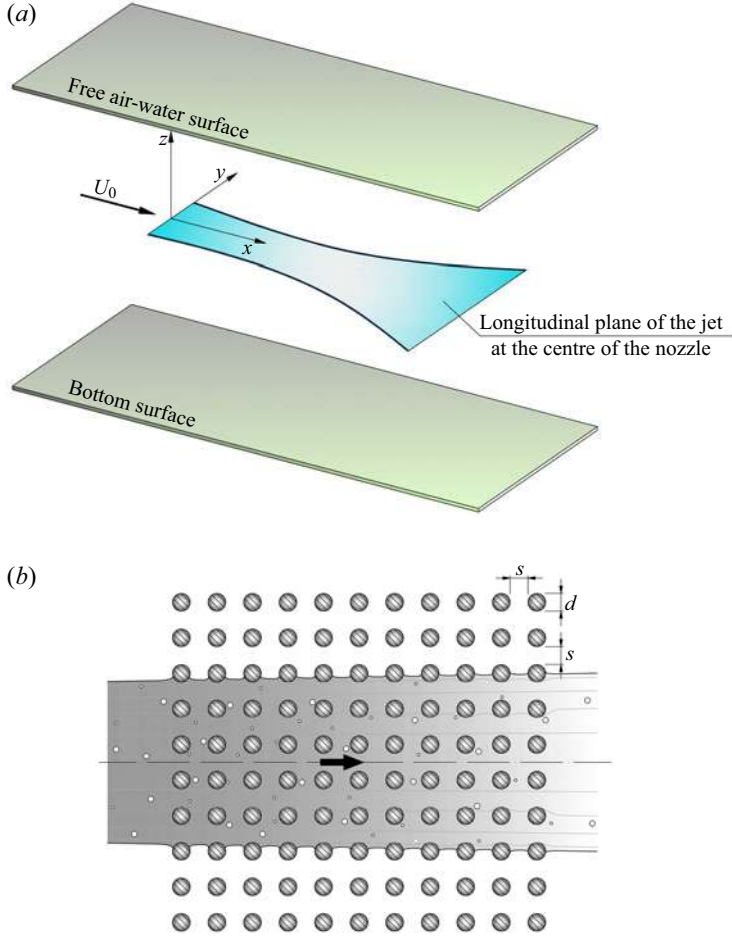

Figure 4. Sketch of the analysed plane jet. (a) Unbounded jet-like flow. (b) Plan view of the jet with the cylinder array.

Assuming \mathcal{B} as the nominal outer boundary of the jet where u is close to 0, it is possible to write

$$\mathcal{B} = \mathcal{C}_b b, \quad (2.9)$$

where \mathcal{C}_b is a constant. Integrating (2.8), with P as the pressure outside the jet and assuming the radius of curvature sufficiently large to have symmetric/antisymmetric conditions for both sides of the jet, we get

$$p = P - \rho \overline{v^2} - \int_0^{\mathcal{B}} (2\rho\Omega u + D_y) dy. \quad (2.10)$$

Differentiating (2.10) with respect to x and using it in (2.7), we get

$$u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} - 2\Omega v = -\frac{1}{\rho} \frac{dP}{dx} + v \frac{\partial^2 u}{\partial y^2} - \frac{\partial \overline{u'v'}}{\partial y} - \frac{\partial}{\partial x} (\overline{u^2} - \overline{v^2}) - \frac{1}{\rho} \left(D_x + \frac{d}{dx} \int_0^{\mathcal{B}} D_y dy + \frac{d}{dx} \int_0^{\mathcal{B}} 2\rho\Omega u dy \right). \quad (2.11)$$

As shown by Mossa *et al.* (2017) and De Serio *et al.* (2018), assuming that

$$D_x \gg \frac{d}{dx} \int_0^{\mathcal{B}} D_y dy \quad (2.12)$$

we obtain

$$\begin{aligned} u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} - 2\Omega v &= -\frac{1}{\rho} \frac{dP}{dx} + v \frac{\partial^2 u}{\partial y^2} - \frac{\partial \overline{u'v'}}{\partial y} - \frac{1}{\rho} D_x - 2\Omega \left(\frac{d}{dx} \int_0^{\mathcal{B}} u dy \right) \\ &= -\frac{1}{\rho} \frac{dP}{dx} + v \frac{\partial^2 u}{\partial y^2} - \frac{\partial \overline{u'v'}}{\partial y} - \frac{1}{\rho} D_x - 2\Omega v_e, \end{aligned} \quad (2.13)$$

where

$$v_e = \frac{d}{dx} \int_0^{\mathcal{B}} u dy \quad (2.14)$$

is the so-called entrainment velocity, which can be written as

$$v_e = \alpha_e u_m, \quad (2.15)$$

with α_e the entrainment/detrainment coefficient (Rajaratnam 1976; Mossa & De Serio 2016). Observing that the laminar and turbulent stresses are, respectively,

$$\begin{cases} \tau_l = \mu \frac{\partial u}{\partial y} \\ \tau_t = -\rho \overline{u'v'} \end{cases} \quad (2.16)$$

and considering that τ_t is much larger than τ_l for the flows here considered and the gradient of pressure is null along the horizontal trajectories in geostrophic flows, which means the trajectories must take place along isochoric lines, we get

$$u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} - 2\Omega v = \frac{1}{\rho} \frac{\partial \tau_t}{\partial y} - \frac{1}{\rho} D_x - 2\Omega v_e. \quad (2.17)$$

Integration of (2.17) gives

$$\rho \int_0^{\mathcal{B}} u \frac{\partial u}{\partial x} dy + \rho \int_0^{\mathcal{B}} v \frac{\partial u}{\partial y} dy - \int_0^{\mathcal{B}} \frac{\partial \tau_t}{\partial y} dy = - \int_0^{\mathcal{B}} (D_x + 2\rho\Omega v_e - 2\rho\Omega v) dy, \quad (2.18)$$

which becomes

$$\frac{1}{2} \frac{d}{dx} \int_0^{\mathcal{B}} \rho u^2 dy + \rho \left(|uv|_{y=0}^{\mathcal{B}} - \int_0^{\mathcal{B}} u \frac{\partial v}{\partial y} dy \right) = - \int_0^{\mathcal{B}} (D_x + 2\rho\Omega v_e - 2\rho\Omega v) dy. \quad (2.19)$$

Using the continuity equation (2.4), we obtain

$$\frac{d}{dx} \int_0^{\mathcal{B}} \rho u^2 dy = - \int_0^{\mathcal{B}} (D_x + 2\rho\Omega v_e - 2\rho\Omega v) dy. \quad (2.20)$$

If we write

$$D_x = \frac{1}{2} \rho C_{Dau}^2 \quad (2.21)$$

we obtain that

$$\frac{d\mathcal{M}(x)}{dx} = \frac{d}{dx} \int_0^{\mathcal{B}} u^2 dy = -\frac{1}{2}C_{Da} \int_0^{\mathcal{B}} u^2 dy - 2\Omega v_e \mathcal{B} + \int_0^{\mathcal{B}} 2\Omega v dy, \quad (2.22)$$

where $\mathcal{M}(x)$ is half the kinematic momentum flux in each cross-section. It is reasonable to assume that the trend of the v -velocity component along y should be antisymmetric with respect to the jet axis (Goertler 1942). The last two terms of the right-hand side of (2.22) are overall responsible for a momentum decrease due to the jet rotation and, using a scale analysis (Tennekes & Lumley 1972), they are similar. Therefore, it is reasonable to write that

$$-2\Omega v_e \mathcal{B} + \int_0^{\mathcal{B}} (2\Omega v) dy = -2\chi_{ve} \Omega v_e \mathcal{B}, \quad (2.23)$$

where χ_{ve} is an empirical coefficient.

2.2. Velocity and cross-length scales

In the zone of established flow of a turbulent plane jet, the velocity distribution is similar (Rajaratnam 1976; Barile *et al.* 2020), so that

$$\frac{u}{u_m} = f(\eta), \quad (2.24)$$

with $\eta = y/b$.

Assuming power forms for u_m and b :

$$\begin{cases} b \propto x^\phi \Rightarrow b = \mathcal{F}_1 x^\phi \\ u_m \propto x^\psi \Rightarrow u_m = \mathcal{F}_2 x^\psi, \end{cases} \quad (2.25)$$

where ϕ and ψ are unknown exponents to be found. Equation (2.25) is valid for the zone of established flow.

By the change of variable $y = \eta/b$, since for $y = 0$ we have $\eta = 0$, and for $y = \mathcal{B}$ we get $\eta = y/b = \mathcal{B}/b = \mathcal{C}_b$, it follows that

$$\frac{d}{dx} \int_0^{\mathcal{C}_b} u_m^2 f^2 b d\eta = -\frac{1}{2}C_{Da} \int_0^{\mathcal{C}_b} u_m^2 f^2 b d\eta - 2\Omega \chi_{ve} v_e \mathcal{B} \quad (2.26)$$

or, analogously,

$$\frac{d}{dx} \left(u_m^2 b \int_0^{\mathcal{C}_b} f^2 d\eta \right) = -\frac{1}{2}C_{Da} u_m^2 b \int_0^{\mathcal{C}_b} f^2 d\eta - 2\Omega \chi_{ve} v_e \mathcal{B}. \quad (2.27)$$

Considering that

$$\int_0^{\mathcal{C}_b} f^2 d\eta = \text{const.}, \quad (2.28)$$

equation (2.27) can be rewritten as

$$\frac{d}{dx} (u_m^2 b) = -\frac{1}{2}C_{Da} b u_m^2 - \frac{2\Omega \chi_{ve} v_e \mathcal{B}}{\int_0^{\mathcal{C}_b} f^2 d\eta}, \quad (2.29)$$

i.e.

$$2\psi + \phi = -\frac{1}{2}C_D a x - \frac{2\Omega \chi_{ve} \alpha_e \mathcal{C}_b x^{1-\psi}}{\int_0^{\mathcal{C}_b} f^2 d\eta}. \quad (2.30)$$

From dimensional considerations it is possible to write that

$$\frac{\tau}{\rho u_m^2} = g(\eta). \quad (2.31)$$

Considering (2.24) and (2.31), denoting the derivatives with a prime symbol, we have

$$f' = \frac{df}{d\eta}, \quad g' = \frac{dg}{d\eta}, \quad b' = \frac{db}{dx}, \quad u'_m = \frac{du_m}{dx}, \quad (2.32a-d)$$

and therefore we obtain

$$u \frac{\partial u}{\partial x} = u_m u'_m f^2 - \frac{u_m^2 b'}{b} \eta f f', \quad (2.33)$$

$$v \frac{\partial u}{\partial y} = \frac{u_m^2 b'}{b} \left(\eta f f' - f' \int_0^\eta f d\eta \right) - u_m u'_m f' \int_0^\eta f d\eta, \quad (2.34)$$

$$\frac{1}{\rho} \frac{\partial \tau}{\partial y} = \frac{u_m^2}{b} g', \quad (2.35)$$

$$-\frac{1}{\rho} D_x = -\frac{1}{2} C_D a u_m^2 f^2, \quad (2.36)$$

$$-2\Omega v_e = -2\Omega \alpha_e u_m. \quad (2.37)$$

Substituting (2.33), (2.34), (2.35) and (2.36) into (2.17), we obtain

$$g' = \frac{b u'_m}{u_m} \left(f^2 - f' \int_0^\eta f d\eta \right) - b' \left(\eta f' - \eta f f' + f' \int_0^\eta f d\eta \right) + \frac{1}{2} C_D a b f^2 + 2\chi_{ve} \Omega \alpha_e u_m. \quad (2.38)$$

Since g' is a function of only η , the right-hand side should also be a function of only η (Mossa *et al.* 2017; Barile *et al.* 2020). Particularly, from the first two terms on the right-hand side, it is possible to write

$$\begin{cases} \frac{b u'_m}{u_m} \propto x^{\phi-1} \\ u_m \\ b' \propto x^{\phi-1}, \end{cases} \quad (2.39)$$

and therefore

$$\phi = 1, \quad (2.40)$$

i.e.

$$b = \mathcal{F}_1 \cdot x. \quad (2.41)$$

In the present study we will consider jets with

$$b = \mathcal{O}(n \cdot s), \quad (2.42)$$

with $n = \mathcal{O}(10-10^2)$. In other words, referring to figure 4(b), we are considering the case where $d/s = \mathcal{O}(10^{-1}-1)$, $b/d = \mathcal{O}(10-10^2)$, $b/s = \mathcal{O}(10-10^2)$, such as that shown by Mossa *et al.* (2017).

Therefore, it is possible to write

$$b = \mathcal{F}_1 x^\phi = \mathcal{O}((10 \div 100) \cdot s). \quad (2.43)$$

The order of magnitude of b changes when it becomes

$$10b = 10\mathcal{F}_1 x^\phi = \mathcal{O}((100 \div 1000) \cdot s), \quad (2.44)$$

i.e. when x^ϕ increases by an order of magnitude or more. Therefore, b has the same order of magnitude between two values of x , i.e. from x_1 to $x_2 > x_1$, when

$$\frac{x_2^\phi}{x_1^\phi} < \mathcal{O}(10). \quad (2.45)$$

Since in the analysed case $\phi = 1$, it is possible to write that

$$x_1, x_2 = \mathcal{O}(n \cdot s) \quad \text{with } n \geq 10-100. \quad (2.46)$$

Furthermore, the rotation rate of the Earth Ω is equal to $7.2921 \times 10^{-5} \text{ rad s}^{-1}$. It can be calculated as $2\pi/T \text{ rad s}^{-1}$, where T is the rotation period of the Earth which is one sidereal day.

Therefore, along a longitudinal distance between x_1 and x_2 satisfying (2.43), equation (2.39) becomes

$$\begin{aligned} g' \approx & \frac{bu'_m}{u_m} \left(f^2 - f' \int_0^\eta f \, d\eta \right) \\ & - b' \left(\eta f' - \eta f f' + f' \int_0^\eta f \, d\eta \right) + \frac{1}{2} C_D \frac{d}{s^2} n s f^2 + O(10^{-5}), \end{aligned} \quad (2.47)$$

where the third term of the right-hand side can be considered approximately constant in the described limits. With these considerations in mind and using (2.39) and (2.30), it is possible to conclude that

$$\begin{cases} \phi = \mathcal{O}(1) \\ \psi = \mathcal{O}\left(-\frac{1}{2}\right) - \frac{1}{4} C_D a x = \mathcal{O}\left(-\frac{1}{2}\right) - \frac{1}{4} C_D \frac{d}{s^2} x = C_p \left(-\frac{1}{2} - \frac{1}{4} C_D \frac{d}{s^2} x\right), \end{cases} \quad (2.48)$$

where, therefore, C_p must have an order of magnitude of 1.

The x coordinate was previously considered as a curvilinear one. We analyse the theoretical model description of the jet each time addressing a relatively small range $x = [x_1, x_2] > x_0$ defined by the order of magnitude of b . With the change of order of magnitude of b , as we move along the jet axis, a new region is defined. Figure 5 shows the described divisions into regions, where X and Y are the axes of a Cartesian coordinate system (Barile *et al.* 2020).

This means that making the laws of b and u_m (equation (2.25)) dimensionless, we have

$$\frac{b}{b_0} = C_1 \left(\frac{x}{x_0} \right)^\phi + C_2, \quad (2.49)$$

$$\frac{u_m}{U_0} = C_3 \left(\frac{x^\psi}{x_0^{\psi_0}} \right) + C_4, \quad (2.50)$$

where ψ_0 is the value of ψ for $x = x_0$. It is reasonable to assume that the coefficients are a function of the range of x . In other words, the structures of the laws of b and u_m remain the same, but the coefficients can vary between the ranges and must be obtained from experiments.

Figure 5. Regions of the jet where, as a first approximation, the order of magnitude of b is constant.

2.3. The momentum flux deficit

Considering (2.9), (2.15) and (2.25), we have the following equation in terms of scale analysis:

$$-2\chi_{ve}\Omega v_e\mathcal{B} = -2\Omega\chi_{ve}\mathcal{C}_b\mathcal{F}_1x^\phi\alpha_e\mathcal{F}_2x^\psi. \quad (2.51)$$

Therefore, integrating (2.22), where the density ρ is not present, since we do not have variation of density, we have

$$\mathcal{M} = c_1e^{-(1/2)C_Dax} - \int 2\Omega\chi_{ve}\mathcal{C}_b\mathcal{F}_1x^\phi\alpha_e\mathcal{F}_2x^\psi dx. \quad (2.52)$$

Making (2.52) non-dimensional for reasons that will be clear afterwards, (2.52) becomes

$$\mathfrak{M} = c_1e^{-(1/2)C_D\mathfrak{a}\mathfrak{x}} - \int 2\mathfrak{D}\chi_{ve}\mathcal{C}_b\mathfrak{F}_1\mathfrak{x}^\phi\alpha_e\mathfrak{F}_2\mathfrak{x}^\psi d\mathfrak{x}, \quad (2.53)$$

where

$$\left. \begin{aligned} \mathfrak{M} &= \frac{\mathcal{M}}{U_0^2x_0}, & \mathfrak{x} &= \frac{x}{x_0}, & \mathfrak{a} &= ax_0, & c_1 &= \frac{c_1}{U_0^2x_0}, & \mathfrak{D} &= \frac{\Omega}{U_0x_0}, \\ \mathfrak{F}_1 &= \frac{\mathcal{F}_1}{x_0}, & \mathfrak{F}_2 &= \frac{\mathcal{F}_2}{U_0} \end{aligned} \right\} \quad (2.54a-g)$$

are all dimensionless. Considering (2.54a-g), the second term of the right-hand side of (2.52) can be rewritten as follows:

$$\int -\mathfrak{C}_1\mathfrak{x}^{0.5-\mathfrak{C}_2\mathfrak{x}} d\mathfrak{x}. \quad (2.55)$$

Integral (2.55) does not have a solution, but we could expand the integrating function. Therefore, we obtain

$$\begin{aligned}\mathfrak{G}_1 \mathfrak{x}^{0.5} - \mathfrak{G}_2 \mathfrak{x} &= \mathfrak{x}^{0.5} \sum_{i=0}^n \frac{(-1)^n}{n!} \mathfrak{G}_1 \mathfrak{G}_2^n \log^n(\mathfrak{x}) \mathfrak{x}^n \\ &= \mathfrak{x}^{0.5} \left(\mathfrak{G}_1 - \mathfrak{G}_1 \mathfrak{G}_2 \log(\mathfrak{x}) \mathfrak{x} + \mathcal{O}(\mathfrak{x})^2 \right).\end{aligned}\quad (2.56)$$

Using a first-order approximation, (2.55) becomes

$$\begin{aligned}\int -\mathfrak{x}^{0.5} (\mathfrak{G}_1 - \mathfrak{G}_1 \mathfrak{G}_2 \log(\mathfrak{x}) \mathfrak{x}) d\mathfrak{x} \\ = -\frac{2}{75} \mathfrak{G}_1 \mathfrak{x}^{3/2} (6\mathfrak{G}_2 \mathfrak{x} - 15\mathfrak{G}_2 \log(\mathfrak{x}) \mathfrak{x} + 25) + \text{const.}\end{aligned}\quad (2.57)$$

Therefore, (2.53) becomes

$$\mathfrak{M} = c_1 e^{-(1/2)C_D a \mathfrak{x}} - \frac{2}{75} \mathfrak{G}_1 \mathfrak{x}^{3/2} (6\mathfrak{G}_2 \mathfrak{x} - 15\mathfrak{G}_2 \log(\mathfrak{x}) \mathfrak{x} + 25) + \text{const.}, \quad (2.58)$$

from which we can compute \mathcal{M} using (2.54a-g). The structure of the first term of the right-hand side of (2.58) is similar to that proposed by Negretti *et al.* (2006) and Mossa & De Serio (2016). Equation (2.58) shows an interesting result, since a pure plane jet in a rotating system does not preserve the momentum. The momentum decrease depends both on the Rossby number, i.e. the rotation, and, in the case of obstructed flows, also on characteristics of the rods. In the case of unobstructed flows, the first term of the right-hand side of (2.58) is not present.

2.4. Jet centreline

As shown by Bradbury (1965), the sum of the first two terms of (2.8) is very small and, therefore, can be neglected, affording

$$0 = -\frac{1}{\rho} D_y - 2\Omega u - \frac{U_b^2}{\frac{dx}{d\alpha}}, \quad (2.59)$$

where α is the central angle of the circumference arc to which the curvilinear segment dx is approximated.

Analysing the trajectory where $u = u_m$, called the jet centreline, using (2.6) for D_y and assuming $U_b^2 = C_u u_m^2$, we have

$$\frac{d\alpha}{dx} = -\frac{\frac{1}{2} \rho C_D a V^2}{\rho (C_u u_m^2)} - 2 \frac{\Omega}{C_u u_m}, \quad (2.60)$$

where C_u is a dimensionless coefficient and V is a velocity scale normal to the jet axis in each cross-section which can be assumed to be equal to

$$V^2 = C_v \alpha_c^2 u_m^2, \quad (2.61)$$

with C_v an empirical coefficient. Therefore, using the second equation of (2.25) and (2.48), we obtain

$$\frac{d\alpha}{dx} = -\frac{1}{2} \frac{C_D a C_v \alpha_e^2}{C_u} - 2 \frac{\Omega}{C_u C_{um} \left(\frac{x}{x_0}\right)^{-1/2 - (1/4)C_D(d/s^2)x}}. \quad (2.62)$$

Equation (2.62) can be written as follows:

$$\frac{d\alpha}{d\left(\frac{x}{x_0}\right)} = -\frac{1}{2} \frac{x_0 C_D a C_v \alpha_e^2}{C_u} - 2 \frac{x_0 \Omega}{C_u C_{um} \left(\frac{x}{x_0}\right)^{-1/2 - (x_0/4)C_D(d/s^2)(x/x_0)}}. \quad (2.63)$$

Using \mathfrak{x} defined in (2.54a–g), we get

$$\frac{d\alpha}{d\mathfrak{x}} = -\frac{1}{2} \frac{x_0 C_D a C_v \alpha_e^2}{C_u} - 2 \frac{x_0 \Omega}{C_u C_{um} \mathfrak{x}^{-1/2 - (x_0/4)C_D(d/s^2)(\mathfrak{x})}}. \quad (2.64)$$

Rewriting (2.64) as

$$\frac{d\alpha(\mathfrak{x})}{d\mathfrak{x}} = -\mathcal{A} - \frac{\mathcal{B}}{\mathfrak{x}^{-C}\mathfrak{x}^{-0.5}}, \quad (2.65)$$

with obvious meaning of the parameters \mathcal{A} , \mathcal{B} , C , which must be obtained from the experimental data, we get the following solution:

$$\alpha(\mathfrak{x}) = -\mathcal{B} \int \mathfrak{x}^{C\mathfrak{x}+1/2} d\mathfrak{x} - \mathcal{A}\mathfrak{x} + c_2, \quad (2.66)$$

where c_2 depends on the initial conditions. In the case of the absence of obstructions, i.e. $C_D = 0$, (2.66) reduces to

$$\alpha(\mathfrak{x}) = -\frac{2}{3}\mathcal{B}\mathfrak{x}^{3/2} + c_2. \quad (2.67)$$

Figures 6 and 7 show typical trends of the jet axis in the absence of obstructions at increasing Rossby numbers and with obstructions at increasing $C_D a x_0$, respectively. The axes of the figures have been made non-dimensional using the length scale L_{x0} , defined as the maximum distance along the direction of the jet exit of the case with $R_o = 1$ with $C_D a x_0 = 0$. They highlight the effects of both Coriolis and drag forces. For the paths in the figures we assumed that all the coefficients and variables are equal to 1, considering that the aim is only a comparison among different values of the Rossby number and the drag force.

3. Model validation

3.1. Experimental apparatus

The experiments were carried out using the Coriolis rotating platform at LEGI-Grenoble, France (figure 8). In this large-scale facility, experimental runs were executed by discharging a horizontal-momentum jet in an unobstructed and obstructed fluid. In the latter case a canopy made of rigid rods was used (figure 9). The LEGI tank has a diameter of 13 m. The water depth used in the experimental runs of the present paper was equal to 0.80 m. Figure 10(a) shows a sketch of the rotating platform with the jet.

Figure 6. Comparison among jet axes without obstructions.

Figure 7. Comparison among centre pathlines of jets with obstructions at different values of $C_D a x_0$.

Jets were horizontally issued with a pipe, installed in the tank at a fixed depth of 0.40 m. The jet initial diameter was equal to 0.08 m (inner diameter of the pipe). A specially designed rigid cylinder array was placed in the tank for the obstructed configurations. The rigid emergent cylinders were in Plexiglas, each with a diameter equal to 0.02 m, arranged on a 2 m × 2 m panel fixed at the bottom of the tank. The rods were manually mounted on the panel inside pre-drilled holes, thus ensuring a regular pattern with a centre-to-centre

distance s . The panel was placed in the tank between the carriage supports, as shown in figure 10(b). The centre of the jet outlet (O) was 1 m from the upstream edge of the panel and 0.77 m from its external edge.

In the present paper, the runs shown in table 1 are analysed. The values of C_D were obtained using the data of Nepf (1999). The Reynolds number of the analysed jets, based on $(2.5a, b)$, was equal to 91×10^3 , ensuring fully turbulent flows.

The instantaneous measurements of the velocity field at the horizontal plane passing from the centre of the jet nozzle were assessed using a particle image velocimetry (PIV) system (figure 9b). The laser source of the PIV system was mounted in the centre of the tank. Three synchronized recording cameras were mounted on the top of the tank. A continuous YAG laser (532 nm wavelength) with a power of 25 W and a Powell prism

producing a 5 mm thick laser sheet were used. The laser sheet, set in a horizontal plane, spanned an area of more than $3 \text{ m} \times 3 \text{ m}$, with a 60° opening angle. The PIV system enabled us to analyse a sufficiently large area of the rotating tank. Its acquisition frequency (33 Hz) was appropriately selected in order to avoid possible effects of disturbances of the free-surface deformations on the measurements. Furthermore, Orgasol neutrally buoyant particles with a $60 \mu\text{m}$ diameter were used to seed the flow. For the processing of the experimental results, custom Matlab scripts have been developed. To account for possible optical distortion due to the presence of the water–air interface, a spatial calibration was applied to all processed images.

Figures 11 and 12 show a comparison between the model and the experiential results for the length scale b and velocity scale u_m , respectively. The comparison between theoretical and experimental results shows that the developed model describes the empirical data very well, at least for the examined experiential set-up. Table 2 lists the values of the coefficients of the theoretical laws for the analysed zones of each experimental run. The analysed zones were identified on the basis of the criteria indicated above.

Figure 13 shows a comparison between the modelled and experimental values of the momentum flux. The figure shows that the momentum deficit predicted by the new model is in very good agreement with the empirical data.

Finally, model predictions of the jet axis path are validated against those obtained in the experiments (figure 14). Table 3 lists the relevant coefficients of equations (2.66) and (2.67) for each of the analysed experimental runs. The results demonstrate the ability of

the model to accurately predict the jet trajectory, accounting for the effects of rotation and obstruction drag forces.

4. Conclusions

This paper investigates the behaviour of a plane jet-like flow in quasi-geostrophic condition issued in an obstructed flow field. Starting from the fundamental principles of mass conservation and momentum balance, the laws of variation of the jet momentum, length scale, velocity scale and centre pathline are derived. In particular, the presented solution shows that (i) the jet length scale b varies linearly with the distance from the jet nozzle and (ii) the jet velocity scale u_m decrease is a function of both the distance from the jet nozzle and the main parameters of the obstructions. The momentum deficit has been theoretically derived, concluding that its decay depends on the main parameters of the Coriolis and drag forces. Particularly, the momentum exhibits an exponential decay along the jet axis. Furthermore, an analytical model of the jet centre pathline has also been derived. The presented solutions show that the velocity scale and momentum decrease faster in the case of obstructed flows. Under the conditions of applicability described in the paper, these analytical solutions have been compared with some experimental data obtained using the Coriolis rotating platform at LEGI-Grenoble (France), showing a good agreement.
