48

Clonal multidrug resistance recently emerged in *Rhodococcus equi*, complicating the 49 50 therapeutic management of this difficult-to-treat animal and human pathogenic actinomycete. The currently spreading multidrug-resistant (MDR) "2287" clone arose in 51 equine farms upon acquisition, and co-selection by mass macrolide-rifampin therapy, of 52 the pRErm46 plasmid carrying the erm(46) macrolides-lincosamides-streptogramins 53 resistance determinant, and an *rpoB*^{S531F} mutation. Here, we screened a collection of 54 susceptible and macrolide-rifampin-resistant R. equi from equine clinical cases using a 55 panel of 15 antimicrobials against rapidly growing mycobacteria (RGM), nocardiae and 56 other aerobic actinomycetes (NAA). R. equi -including MDR isolates- was generally 57 susceptible to linezolid, minocycline, tigecycline, amikacin and tobramycin according to 58 59 Staphylococcus aureus interpretive criteria, plus imipenem, cefoxitin and ceftriaxone 60 based on Clinical & Laboratory Standards Institute (CLSI) guidelines for RGM/NAA. 61 Ciprofloxacin and moxifloxacin were in the borderline category according to European Committee on Antimicrobial Susceptibility Testing (EUCAST) criteria. Molecular analyses 62 63 linked pRErm46 to significantly increased MICs for trimethoprim-sulfamethoxazole and doxycycline in addition to clarithromycin within the RGM/NAA panel, and to streptomycin, 64 spectinomycin and tetracycline resistance. pRErm46 variants with spontaneous deletions 65 66 in the class 1 integron (C1I) region, observed in $\approx 30\%$ of *erm*(46)-positive isolates, indicated that the newly identified resistances were attributable to C1I's sulfonamide 67 68 (sul1) and aminoglycoside (aaA9) resistance cassettes and adjacent tetRA(33) determinant. Most MDR isolates carried the rpoB^{S531F} mutation of the 2287 clone, while 69 70 different rpoB mutations (S531L, S531Y) detected in two cases suggest the emergence 71 of novel MDR R. equi strains.

72

Journal of Clinical Microbiology

73	Rhodococcus equi is a soil-borne facultative intracellular actinomycete that causes chronic
74	pyogranulomatous infections in animals and immunocompromised people (1-3). Young foals
75	are particularly susceptible to R. equi carrying the equine-specific virulence plasmid pVAPA
76	(4-7) and develop a life-threatening purulent bronchopneumonia with frequent
77	extrapulmonary involvement (1, 8). No effective vaccine is currently available and control of
78	the disease largely relies on prolonged courses of antimicrobial therapy (9, 10).
79	Many antimicrobials are active against R. equi in vitro but their clinical efficacy or
80	applicability is compromised for a variety of reasons, such as poor intracellular penetration,
81	reduced oral bioavailability, inadequate pulmonary pharmacokinetics, undesirable effects in
82	foals, or lack of randomized efficacy studies (11). Intrinsic and mutational resistance,
83	compounded by the permeability barrier afforded by a mycolic acid-containing cell envelope
84	similar to that of Mycobacterium and other actinomycetes, may also result in inconsistent
85	drug susceptibility, as reported for chloramphenicol, β -lactams or quinolones (12-22).
86	Consequently, co-administration of a macrolide (erythromycin, later clarithromycin or
87	azithromycin) and rifampin has remained the mainstay therapy against foal rhodococcosis
88	since clinical experience in the 1980's (23, 24), further supported by in vitro (15, 25, 26) and
89	in vivo (27) experimental data, demonstrated the efficacy of this drug combination (11).
90	While rifampin resistance caused by $rpoB$ mutations has been regularly reported in R .
91	equi (15, 20, 21, 28), resistance to macrolides only recently emerged, interestingly, always
92	associated with rifampin resistance (29, 30). Dual resistance to macrolides and rifampin was
93	first detected in the late 1990's in equine farms where mass macrolide-rifampin
94	antibioprophylaxis was systematically practiced (31, 32), and is more frequent among foals
95	exposed to the macrolide-rifampin combination (33, 34). Macrolide resistance was found to
96	be mediated by erm(46), a novel self-transmissible rRNA methylase determinant conferring
97	cross-resistance to lincosamides and streptogramins B (MLSB) (30). erm(46) is carried on a
98	conjugative plasmid, pRErm46 (35), as part of a 6.9-kb transposon, TnRErm46. The latter is

ournal of Clinical Microbioloav highly mobile and becomes stabilized in *R. equi* by actively transposing onto the host genome and the pVAPA virulence plasmid (35). Despite pRErm46's high conjugal transferability, *erm*(46) remains largely restricted to a clonal *R. equi* subpopulation characterized by a unique $rpoB^{S531F}$ mutation, presumably as a result of strong co-selection driven by the combination therapy (35, 36). pRErm46 has recently been shown to also confer tetracycline resistance via a *tetRA*(33) determinant associated to a class 1 integron (C1I) (35) virtually identical to those found in the corynebacterial plasmid pTET3 (37).

The erm(46)-carrying multidrug-resistant (MDR) R. equi clone, designated 2287 (35, 106 107 36), is increasingly prevalent across equine farms in the USA, is likely to spread 108 internationally (36), and poses a substantial threat because of the lack of clinically-proven 109 alternative antimicrobials to treat affected foals. The aim of this study was (i) to determine the 110 genetic basis of macrolide resistance in *R. equi* equine isolates from Kentucky, USA, where 111 foal rhodococcosis is endemic and MDR 2287 was first identified (31); and (ii) to assess the 112 activity against MDR R. equi of a panel of antimicrobials used for susceptibility testing of 113 closely related rapidly growing mycobacteria (RGM) and nocardiae/other aerobic 114 actinomycetes (NAA).

115

116 MATERIALS AND METHODS

Bacteria. The R. equi isolates analyzed in this study were recovered from 70 117 necropsied foals with severe rhodococcal infection diagnosed between 1989 to 2019 at the 118 University of Kentucky Veterinary Diagnostic Laboratory (UKVDL). Necropsy specimens 119 120 typically included lung, liver, small intestine, colon and any other organ/tissues with R. equicompatible lesions. Isolation was performed on blood agar, Columbia (colistin/nalidix acid) 121 agar and eosin methylene blue agar plates incubated at 37 °C microaerophilically for 24 h 122 followed by a minimum additional 24 h aerobically. R. equi identification was based on 123 124 standard criteria including colony morphology, gram staining, biochemical tests, CAMP-like

125	co-operative hemolysis with sphingomyelinase C-producing indicator bacteria (S. aureus or
126	Listeria ivanovii) (38, 39), and PCR detection of the R. equi-specific choE and vapA gene
127	markers (40, 41). R. equi isolates were stored at -80 °C until used.
128	<i>In vitro</i> susceptibility testing. Inocula containing $\approx 1 \times 10^5$ CFU as verified by plate
129	counting were prepared by the direct colony suspension method according to CLSI
130	guidelines. Minimal inhibitory concentrations (MICs) for erythromycin and rifampin (and
131	confirmatory determinations for trimethoprim-sulfamethazole [TMP-SMX] and tetracycline)
132	were performed using gradient concentration Etest® strips as per the manufacturer's
133	instructions (BioMérieux, Durham, NC and Basingstoke, Hampshire, UK) using
134	Staphylococcus aureus ATCC 29213 and Enterococcus faecalis ATCC 29212 as controls.
135	Since there are currently no approved breakpoint criteria for susceptibility testing of R. equi in
136	horses, interpretation was extrapolated from MIC-based human interpretative criteria
137	(erythromycin: S $\leq 0.5 \ \mu g/ml$, I = 1-4 $\mu g/ml$, R $\geq 8 \ \mu g/ml$; rifampin: S $\leq 1 \ \mu g/ml$, I = 2 $\mu g/ml$, R
138	\geq 4 µg/ml) (42). Susceptibility testing for antimicrobials against RGM and NAA was
139	performed by the broth microdilution method using Sensititre [™] RapMyco AST Plates (Trek
140	diagnostics, Thermo Fisher Scientific, Grand Island, NY), comprising the following 15
141	antimicrobials: amikacin, amoxicillin/clavulanic acid, cefepime, cefoxitin, ceftriaxone,
142	ciprofloxacin, clarithromycin, doxycycline, imipenem, linezolid, minocycline, moxifloxacin,
143	tigecycline, tobramycin, and TMP-SMX. S. aureus ATCC 29213 and Mycobacterium
144	peregrinum ATCC 700686 were used as controls as per CLSI guidelines (43). Susceptibility
145	to different aminoglycosides was determined by the diffusion method using the following
146	disks (Oxoid, Basingstoke, Hampshire, UK): streptomycin (S, 25µg), spectinomycin (SH, 25
147	μ g), gentamicin (CN, 50 μ g), kanamycin (K, 30 μ g) and apramycin (APR, 15 μ g).
148	Molecular characterization of MDR R. equi and pRErm46. Total bacterial DNA
149	was prepared by heating isolated colonies at 100 $^{\circ}\text{C}$ in 100 μl of ultrapure water and
150	centrifugation for 90 s at 16,000 × g. PCR reactions were carried out using Quick-load 2× Taq

JCM

151	master mix (New England Biolabs) as previously described (30). Oligonucleotide primers
152	used are listed in Table S1. RpoB substitutions were determined by sequencing an 827-bp
153	rpoB region amplified by PCR from R. equi genomic DNA using previously reported
154	oligonucleotides primers (20) and Kapa HiFi HotStart ReadyMix (Roche). PCR amplicons
155	were purified from agarose gels using QIAquick kit (Qiagen, Manchester, UK) and sequenced
156	by the Sanger method at Source BioScience (Nottingham, UK). The deduced amino acid
157	sequence was aligned to the RpoB sequence from the R. equi 103S reference genome
158	(accession no. FN563149) (13) using Clustal Omega
159	(https://www.ebi.ac.uk/Tools/msa/clustalo/).
160	Statistical analysis. MIC ₅₀ /MIC ₉₀ values were determined as previously
161	reported (44). Data were also analyzed by descriptive statistics including modal MICs (the
162	most common MIC), average and range when appropriate. The statistical significance of the
163	differences in the MICs was calculated using Mann-Whitney, Kruskal-Wallis or Fisher's
164	exact test. Data were analyzed using GraphPad Prism version 9.1.0 software for Mac,

165 GraphPad Software, San Diego, California USA (<u>www.graphpad.com</u>).

166

167 **RESULTS**

Resistance to macrolides and rifampin. We analyzed a selection of 70 R. equi 168 169 clinical strains recovered post-mortem from severe cases of foal rhodococcosis, including 15 170 macrolide-resistant isolates identified through erythromycin susceptibility screening (modal MIC 24/32 µg/ml, range 8-96 µg/ml) (Table 1). All erythromycin-resistant (Erm^R) isolates 171 also showed high rifampin MICs (≥32 µg/ml), consistent with the previously reported dual 172 Erm^R/rifampin-resistant (Rif^R) phenotype of the *R. equi* 2287 clone (35, 36). The remaining 173 strains were erythromycin susceptible (Erm^{S} , MIC_{90} 0.75/1 µg/ml, range 0.016-6 µg/ml) and 174 included 21 Rif^R isolates (MIC₉₀ \geq 32 µg/ml) (Table 1). 175

176Molecular characterization. Using a previously described PCR test (30), erm(46)177was detected in 14 of the 15 $\mathrm{Erm}^{\mathrm{R}}/\mathrm{Rif}^{\mathrm{R}}$ isolates (Table 1). Sequencing of the rpoB gene178determined that 13 of the 14 erm(46)-positive $\mathrm{Erm}^{\mathrm{R}}/\mathrm{Rif}^{\mathrm{R}}$ isolates carried the Ser531Phe179substitution (TCG \rightarrow TTC transversion) characteristic (and so far unique) (35, 36) to the MDR1802287 clone (35). The other erm(46)-positive isolate carried a distinct RpoB substitution also at181position 531 within the rifampin resistance determining region (RRDR-1), Ser531Leu,

182 previously described in *R. equi* several times (20, 21, 45).

The only erm(46)-negative Erm^{R}/Rif^{R} isolate also carried a distinct rpoB mutation, 183 again at position 531, resulting in a Ser \rightarrow Tyr substitution not described before in clinical 184 isolates of *R. equi*. An *rpoB*^{S531Y} substitution was recently reported by Huber et al. in an Erm^R 185 186 clonal R. equi population apparently restricted to the environment and which carried a variant erm(46) gene, designated erm(51) (46). Attempts to detect erm(51) in our erm(46)-negative 187 Erm^R isolate (and all other Erm^R strains plus a selection of Erm^S isolates) using different 188 primer sets (Table S1) were unsuccessful. Moreover, the rpoB Tyr531 codon in the 189 erm(46)/erm(51)-negative isolate (TAC) is different from that found in the erm(51)-positive 190 clonal isolates (TAT) (46), indicating that both correspond to genetically distinct Erm^R/Rif^R 191 R. equi subpopulations. 192

erm(46) was not detected in any of the 21 Erm^S/Rif^R isolates nor the 34 susceptible *R*. *equi* clinical isolates (Table 1). Analysis of the *rpoB* sequences from the Erm^S/Rif^R isolates
identified different RpoB substitutions (to be described elsewhere). As expected, no *rpoB*mutations were found in a random selection of the Rif^S isolates.

197 Screening against antimicrobial panel for related pathogenic actinomycetes. Most 198 of the 15 RapMyco antimicrobials for RGM/NAA susceptibility testing were active against *R*. 199 *equi* irrespective of the Erm/Rif phenotype. MIC₉₀'s were $\leq 1 \mu$ g/ml for linezolid, minocycline 200 and tigecycline, 1 µg/ml for ciprofloxacin and moxifloxacin, 1 to 2 µg/ml for doxycycline and 201 tobramycin, 2 µg/ml for amikacin, $\leq 2 \mu$ g/ml for imipenem, and $\leq 4 \mu$ g/ml for ceftriaxone.

Higher MIC₉₀'s were observed for cefoxitin, cefepime and amoxicillin-clavulanic (16 µg/ml)
(Table 2).

Significant MIC differences between Erm^R and Erm^S isolates were observed, as 204 expected, for the macrolide clarithromycin (8 to $\geq 16 \mu g/ml$ vs 0.06-0.5 $\mu g/ml$, respectively; P 205 <0.0001), but interestingly also TMP-SMX (>8 and 2 µg/ml, respectively; P = 0.0025) (Table 206 2). The differential TMP-SMX susceptibility was confirmed using gradient MIC Etest strips 207 (>32 µg/ml for Erm^R, 0.5-1 µg/ml for Erm^S; Table 3). Diffusion essays with sulfamethoxazole 208 disks showed it was linked to sulfonamide resistance (no halo for most Erm^R isolates. 209 210 27.3 ± 2.4 mm mean diameter for Erm^s ones). pRErm46-mediated sulfonamide resistance. pRErm46's C1I carries a sul1 gene 211 (35) (Fig. 1) that could explain the association between macrolide and TMP-SMX resistances 212 in MDR R. equi (47). Using specific PCR primers (Table S1), we confirmed that all isolates 213 displaying sulfamethoxazole resistance (Smx^R) possessed *sul1* and associated C1I genes, 214 whereas all Smx^s strains were negative (Table 3). 215 A notable exception was the prototype strain of the MDR 2287 clone, PAM 2287 (35), 216 which we tested as a control. Despite carrying the sull gene (35), PAM 2287 was susceptible 217 to TMP-SMX (MIC 1 μ g/ml) unlike most members of the 2287 clonal population (MIC >32 218 μ g/ml, determined by Etest). This is likely because, in PAM 2287's pRErm46, a copy of the 219 TnRErm46 transposon is inserted within the C11's aadA9 gene (35), preventing read-through 220 transcription of the downstream *sul1* cassette from the integron's promoter (Fig 1). 221 222 While there was 100% correlation between the presence of a functional sull and sulfonamide resistance, not all erm(46)-positive Erm^{R} isolates exhibited an Smx^{R} phenotype. 223

- 224 Specifically, six (43%) of the 14 *erm*(46)-positive isolates showed low TMP-SMX MICs
- similar to those of the Erm^S group (1 2 μ g/ml vs >8 μ g/ml for Erm^R strains, P = 0.69) (Table
- 3). This profile would be expected in case of pRErm46 plasmid loss with retention of the

erm(46) (Tn*RErm*46) element by transposition onto the host genome, observed in a
proportion of MDR *R. equi* isolates (35, 36).

229 To examine the above possibility, we assessed the presence of pRErm46 indirectly by using the C1I-associated tetRA(33) tetracycline resistance determinant (36) as a phenotypic 230 231 marker using Etest strips, and directly by PCR mapping with primers targeting the plasmid 232 backbone and the C11-tetRA(33) region (Table S1). This analysis showed that three of the six erm(46)-positive/Smx^s isolates were indeed negative to all pRErm46 markers. However, the 233 three others retained the pRErm46 backbone but were negative to C1I and tetRA(33), 234 235 consistent with the deletion of this region, previously observed in a subset of MDR 2287 236 isolates (36). The data also revealed a perfect correlation between the sulfonamide and tetracycline susceptibility phenotypes (Table 3), except in one case. This single Smx^R and 237 238 tetracycline susceptible isolate was positive to all pRErm46 markers except *tetRA*(33) (Table 239 3), suggesting a specific deletion of the latter. The pRErm46 C11/tetRA(33) deletions were 240 confirmed by PCR mapping using external primers (Fig. 1, Table S1). 241 Collectively, our results indicate that pRErm46 also confers resistance to sulfonamides in addition to macrolides and tetracycline in R. equi, and that complete or partial deletions of 242 243 the C1I-tetRA(33) region (Fig 1) take place in a proportion of the plasmid population (4 of 14 244 plasmids analyzed), resulting in corresponding loss of sulfonamide and/or tetracycline 245 resistance. Other pRErm46-associated antimicrobial resistances. pERrm46's C1I also codes 246 for an aminoglycoside-modifying enzyme identical to the ANT(3")-Ia family 247 248 adenylyltranferase encoded by the aadA9 cassette from the homologous C1I of the pTET3 plasmid from Corynebacterium glutamicum LP-6 (37). Consistent with the substrate range of 249 the corynebacterial AadA9 enzyme (37), disk diffusion assays showed that all R. equi isolates 250 251 carrying a pRErm46 plasmid with intact C1I (n = 8) were resistant to streptomycin and 252 spectinomycin but susceptible to a range of other aminoglycosides (gentamicin, kanamycin

Downloaded from https://journals.asm.org/journal/jcm on 06 August 2021 by 192.41.125.253.

253	and apramycin in addition to amikacin and tobramycin), whereas those carrying C1I-deleted
254	plasmids (and pRErm46-negative isolates) were susceptible (Table 4). Of note, the prototype
255	MDR 2287 strain, PAM 2287, which carries a TnRErm46-disrupted aadA9 cassette (see
256	above and Fig. 1), was also susceptible to streptomycin and spectinomycin.
257	Finally, while there were no significant differences in doxycycline susceptibility
258	between <i>erm</i> (46)-positive (Erm ^R) and -negative (Erm ^S) isolates in the global analysis (Table
259	2), consistent with previous reports (34, 35), there was a small but significant increase in the
260	MIC for the $erm(46)$ -positive Erm ^R isolates carrying $tetRA(33)$ compared to those lacking the
261	tetracycline resistance determinant (modal MIC 2 μ g/ml, range 1-2 μ g/ml vs 1 μ g/ml, range
262	0.12-1 μ g/ml; <i>P</i> <0.0001). These data indicate that the TetA(33) efflux pump system encoded
263	in pRErm46 confers some degree of cross-resistance to the semisynthetic tetracycline,
264	doxycycline.

265

278

266 DISCUSSION

The emergence of MDR R. equi renders ineffective the macrolide-rifampin 267 combination used as mainstay therapy against foal rhodococcosis (11) and, often, in the 268 269 treatment of human rhodococcal infections (2, 19). To aid in the identification of alternative 270 drugs, we used a panel of antimicrobials for susceptibility testing of RGM and NAA, to which *R. equi* is phylogenetically, pathogenically and physiologically closely related. We found that 271 272 the pRErm46 MLSB resistance plasmid of MDR R. equi (35) also confers resistance to 273 sulfonamides and, at low level, doxycycline (see below), both recognized as potential 274 therapeutic options against R. equi (3, 9, 11, 23, 48, 49). 275 Sulfonamide resistance is linked to the *sul1* cassette of pRErm46's C1I. Horizontally 276 acquired sull genes encode alternative dihydropteroate synthase (DHTS) enzymes that functionally complement the core bacterial DHTS, allowing to bypass the inhibitory effect of 277

sulfonamides (47). Doxycycline resistance is conferred by the tetRA(33) element adjacent to

279	the C1I (Fig 1), previously linked to pRErm46-specified tetracycline resistance (35), which
280	we confirm here. We also report that pRErm46 additionally encodes streptomycin and
281	spectinomycin resistance via pRErm46's C1I aadA9 cassette (37) (Fig 1).
282	Our data show that all the newly identified non-MLSB resistances can be lost by either
283	(i) spontaneous deletion of the plasmid's C1I-tetRA(33) region (36), presumably by
284	homologous recombination between the flanking directly repeated IS6100 copies (50, 51)
285	(Fig 1); or (ii) pRErm46 curing after transposition of the TnRErm46 element to the host
286	genome (35). Although based on the analysis of a limited number of Erm ^R /Smx ^S /Tet ^S isolates,
287	both events appear to occur at similar frequency in the MDR R. equi population. pRErm46
288	Δ C1I- <i>tetRA</i> (33) variants are increasingly observed among clonal MDR 2287 isolates (36)
289	(29% in this study), possibly reflecting genetic dispensability due to lack of antibiotic
290	selection, because neither sulfonamides nor streptomycin, spectinomycin or tetracycline (and
291	doxycycline) are used in the mass R. equi antibioprophylaxis at equine farms. We also show
292	that deletion of the $tetRA(33)$ locus alone, causing loss of tetracycline –but not the C1I-
293	specified sulfonamide (and streptomycin-spectinomycin)- resistance (Fig 1, Tables 3 and 4),
294	can also occur, as detected in one of the Erm ^R isolates.
295	Consistent with the known substrate range of tetracycline resistance mechanisms (52),
296	pRErm46's TetA(33) efflux pump seems inactive against minocycline and tigecycline. For
297	doxycycline, a word of caution is in order because the $tetRA(33)$ determinant was associated
298	with a statistically significant increase in the MIC from 0.5-1 μ g/ml to 2 μ g/ml (Table 3).
299	While perhaps not clinically relevant in humans, the poor oral bioavailability of doxycycline
300	in adult horses (53, 54) makes MDR R. equi isolates carrying pRErm46 plasmids with an
301	intact <i>tetRA</i> (33) locus to be classified as doxycycline resistant according to CLSI's criteria for
302	this animal species (PK/PD breakpoint \geq 0.5 µg/ml) (42). Although doxycycline's
303	pharmacokinetic variables are more favorable in foals, maximum serum activity values (C_{max}
304	2.54 and 2.89 $\mu g/ml$ after intragrastric administration of 10 and 20 mg/kg) (48) would remain

305	close to the MIC in MDR 2287 (2 $\mu g/ml),$ meaning it might be difficult to achieve the two- to
306	four-times over-MIC concentrations required for time-dependent antibacterial activity (55).
307	Moreover, doxycycline may also contribute to pRErm46 selection, either in R. equi or in other
308	members of the environmental microbiota in which it can be potentially maintained (56)
309	In the absence of specific interpretive guidelines, S. aureus breakpoints are tentatively
310	applied to R. equi (43, 57). This may in certain cases be inapplicable because of lack of
311	breakpoint criteria for some antimicrobials, and even be questionable given the significant
312	drug susceptibility-relevant physiological differences between S. aureus and R. equi. For
313	example, β -lactam susceptibility testing in <i>S. aureus</i> relies on the cephalosporin, cefoxitin, as
314	a marker of mecA/mecC-mediated methicillin-resistance (MRSA) and predictor of resistance
315	to all antibiotics within this group, including cephems and carbapenems (58). With these
316	criteria, <i>R. equi</i> would be resistant to cefoxitin and, by inference, generally to all β-lactams.
317	This is at odds with an interpretation based on RGM and/or NAA criteria (43, 59), with which
318	<i>R. equi</i> would be susceptible to imipenem (MIC ₉₀ $\leq 2 \mu g/ml$), ceftriaxone (MIC ₉₀ $\leq 4 \mu g/ml$)
319	and cefoxitin (MIC ₉₀ 16 μ g/ml), and intermediate to cefepime and amoxicillin/clavulanate
320	(MIC ₉₀ 16 μ g/ml). The RGM/NAA guidelines take into account that MICs tend to be higher
321	in this bacterial group owing to their less permeable cell envelope or typical abundance of
322	intrinsic resistance mechanisms (e.g. the <i>R. equi</i> 103S genome encodes 10 putative β -
323	lactamase homologs and an array of 11 penicillin-binding proteins [13]).
324	To circumvent these problems, we interpreted the R. equi susceptibility data by
325	integrating CLSI's criteria for S. aureus (57) and RGM/NAA (43, 59), and the EUCAST
326	criteria for both S. aureus and corynebacteria (60). Based on MIC ₉₀ values, R. equi clinical
327	isolates, including Erm ^R (MDR) strains, can be considered to be generally susceptible to
328	linezolid, minocycline, tigecycline, amikacin and tobramycin. Linezolid and tigecycline reach
329	satisfactory plasma and pulmonary concentrations and would be adequate candidates,
330	eventually in combination, to treat R. equi infections (61). However, both are listed as

Journal of Clinical	Microbiology

332Minocycline can be administered orally with good bioavailability and offers potentially333favorable pharmacokinetic characteristics to treat equine rhodococcosis (63, 64), although a334caveat is that it was found to be inactive against <i>R. equi</i> in a nude mouse infection model (65).335Amikacin was also found to be weakly effective against <i>R. equi</i> in nude mice, possibly related336to a high frequency of resistant mutants and limited intracellular uptake (65), while the337effectiveness window for tobramycin according to pharmacokinetic studies in horses (MIC of3381 to 2 µg/ml) (66) may be too close to the <i>R. equi</i> MIC. However, both aminoglycosides may339be useful in combination to other antimicrobials. Although assumed to be largely resistant to340β-lactams based on the relatively high MICs (15, 19, 67-73), the application of the341RGM/NAA breakpoints may enable a wider the use of these antibiotics against MDR <i>R. equi</i> ,342eventually in combination with β-lactamase inhibitors and other antimicrobials, as343exemplified with the highly drug-resistant <i>Mycobacterium abscessus</i> (74). While β-lactams344do not concentrate intracellularly, they permeate into mammalian cells and display345intracellular activity (75, 76), as observed with ceftiofur and imipenem in equine monocyte-346derived macrophages infected with <i>R. equi</i> (77). With a MICs_0 of 1 µg/ml (Table 2),347ciprofloxacin and moxifloxacin would be also largely active against <i>R. equi</i> , consistent with348previously reported data (2, 11, 17, 78). However, susceptibility to ciprofloxacin would be <tr< th=""><th>331</th><th>critically important antibiotics in human medicine (62) and their use in animals is restricted.</th></tr<>	331	critically important antibiotics in human medicine (62) and their use in animals is restricted.

348previously reported data (2, 11, 17, 78). However, susceptibility to ciprofloxacin would be349borderline while moxifloxacin would fall in the resistance category according to EUCAST350criteria, more stringent based on PK/PD analyses and the potential impact of low-level351resistance on clinical outcomes (resistance breakpoints for <i>S. aureus</i> /corynebacteria >1 µg/ml352for ciprofloxacin, 0.25/0.5 µg/ml for moxifloxacin) (60). Of note, a poor response to353fluoroquinolones has been invoked in human <i>R. equi</i> infections (14, 17, 69, 71, 79, 80).354Quinolones are also associated with risks of arthropathy in foals (11).355Finally, our data further confirm the predominance of the MDR 2287 clonal356population, characterized by the <i>rpoB</i> Ser531Phe mutation (35, 36), among Erm ^R equipe	347	ciprofloxacin and moxifloxacin would be also largely active against R. equi, consistent with
349borderline while moxifloxacin would fall in the resistance category according to EUCAST350criteria, more stringent based on PK/PD analyses and the potential impact of low-level351resistance on clinical outcomes (resistance breakpoints for <i>S. aureus</i> /corynebacteria >1 μ g/ml352for ciprofloxacin, 0.25/0.5 μ g/ml for moxifloxacin) (60). Of note, a poor response to353fluoroquinolones has been invoked in human <i>R. equi</i> infections (14, 17, 69, 71, 79, 80).354Quinolones are also associated with risks of arthropathy in foals (11).355Finally, our data further confirm the predominance of the MDR 2287 clonal356population, characterized by the <i>rpoB</i> Ser531Phe mutation (35, 36), among Erm ^R equipe	348	previously reported data (2, 11, 17, 78). However, susceptibility to ciprofloxacin would be
 criteria, more stringent based on PK/PD analyses and the potential impact of low-level resistance on clinical outcomes (resistance breakpoints for <i>S. aureus</i>/corynebacteria >1 µg/ml for ciprofloxacin, 0.25/0.5 µg/ml for moxifloxacin) (60). Of note, a poor response to fluoroquinolones has been invoked in human <i>R. equi</i> infections (14, 17, 69, 71, 79, 80). Quinolones are also associated with risks of arthropathy in foals (11). Finally, our data further confirm the predominance of the MDR 2287 clonal population, characterized by the <i>rpoB</i> Ser531Phe mutation (35, 36), among Erm^R equine 	349	borderline while moxifloxacin would fall in the resistance category according to EUCAST
 resistance on clinical outcomes (resistance breakpoints for <i>S. aureus</i>/corynebacteria >1 µg/ml for ciprofloxacin, 0.25/0.5 µg/ml for moxifloxacin) (60). Of note, a poor response to fluoroquinolones has been invoked in human <i>R. equi</i> infections (14, 17, 69, 71, 79, 80). Quinolones are also associated with risks of arthropathy in foals (11). Finally, our data further confirm the predominance of the MDR 2287 clonal population, characterized by the <i>rpoB</i> Ser531Phe mutation (35, 36), among Erm^R equine 	350	criteria, more stringent based on PK/PD analyses and the potential impact of low-level
 for ciprofloxacin, 0.25/0.5 μg/ml for moxifloxacin) (60). Of note, a poor response to fluoroquinolones has been invoked in human <i>R. equi</i> infections (14, 17, 69, 71, 79, 80). Quinolones are also associated with risks of arthropathy in foals (11). Finally, our data further confirm the predominance of the MDR 2287 clonal population, characterized by the <i>rpoB</i> Ser531Phe mutation (35, 36), among Erm^R equine 	351	resistance on clinical outcomes (resistance breakpoints for S. aureus/corynebacteria >1 μ g/ml
 fluoroquinolones has been invoked in human <i>R. equi</i> infections (14, 17, 69, 71, 79, 80). Quinolones are also associated with risks of arthropathy in foals (11). Finally, our data further confirm the predominance of the MDR 2287 clonal population, characterized by the <i>rpoB</i> Ser531Phe mutation (35, 36), among Erm^R equipe 	352	for ciprofloxacin, 0.25/0.5 μ g/ml for moxifloxacin) (60). Of note, a poor response to
 Quinolones are also associated with risks of arthropathy in foals (11). Finally, our data further confirm the predominance of the MDR 2287 clonal population, characterized by the <i>rpoB</i> Ser531Phe mutation (35, 36), among Erm^R equipe 	353	fluoroquinolones has been invoked in human R. equi infections (14, 17, 69, 71, 79, 80).
Finally, our data further confirm the predominance of the MDR 2287 clonal population, characterized by the <i>rpoB</i> Ser531Phe mutation (35, 36), among Erm ^R equipe	354	Quinolones are also associated with risks of arthropathy in foals (11).
population, characterized by the <i>rpoB</i> Ser531Phe mutation (35, 36), among Erm^{R} equine	355	Finally, our data further confirm the predominance of the MDR 2287 clonal
r_{r}	356	population, characterized by the $rpoB$ Ser531Phe mutation (35, 36), among Erm ^R equine

357	clinical isolates (90%). One pRErm46-narboring isolate carried a distinct <i>rpoB</i> substitution,
358	Ser531Leu, indicative of spillover of pRErm46 to other R. equi genotypes and potential
359	emergence of novel MDR clones carrying different <i>rpoB</i> mutations (36). We also identified
360	an Erm ^R /Rif ^R isolate with a novel <i>rpoB</i> Ser531Tyr mutation (recently also found in an
361	emerging MDR clone in Kentucky) (36) in which neither erm(46)/pRErm46 markers nor the
362	erm(51) variant recently discovered in environmental isolates of R. equi (46), were detected.
363	This strain warrants further investigation and indicates that diverse resistance mechanisms are
364	being actively selected in R. equi in response to the antibiotic pressure imposed by the
365	macrolide-rifampin combination therapy commonly used at equine farms.
366	In summary, this study adds to the known resistance spectrum of pRErm46
367	(macrolides, lincosamides, streptogramins and tetracycline) four additional antimicrobials
368	(sulfonamides/trimethoprim-sulfamethoxazol, doxycycline, streptomycin and spectinomycin),
369	and identifies alternative drugs for potential consideration in the treatment of infections by
370	MDR R. equi.

ACKNOWLEDGEMENTS 372

373 We thank the members of Bacteriology, Pathology, Molecular Diagnostics and other sections 374 of the University of Kentucky Veterinary Diagnostic Laboratory for their routine diagnostic work. The 375 Horserace Betting Levy Board, UK, is gratefully acknowledged for supporting this study (grant prj-376 796 to JV-B). The funder had no role in study design, data collection and interpretation, or the 377 decision to submit the work for publication. We declare no conflict of interest.

378

617

618	Fig. 1. Schematic representation of the antimicrobial resistance elements of pRErm46 from
619	R. equi MDR 2287. The TnRErm46 mobile element is represented in pale red with the
620	ISRe46 transposase highlighted in deep red and the macrolides-lincosamides-streptogramins
621	(MLS) resistance determinant erm(46) in black. TnRErm46 is highly mobile and can be
622	present in several copies in the pRErm46 plasmid and the host genome, including the
623	pVAPA virulence plasmid (35). The class 1 integron (C1I) with integrase gene (intI1) and
624	aminoglycoside (aadA9) and sulfonamide (sul1) resistance cassettes are represented in
625	yellow, the adjacent $tetRA(33)$ tetracycline resistance element in green, and the flanking
626	IS6100 copies in magenta. The C1I and tetRA(33) elements are found in a 100% identical
627	(but reverse) arrangement in the pTET3 plasmid from C. glutamicum (35,37), suggesting
628	that they can be mobilized en bloc via the $IS6100s$. Deletion of both elements, or only
629	tetRA(33), presumably via homologous recombination between the directly repeated IS6100
630	copies (35, 50, 51), are observed in a proportion of the MDR 2287 isolates and result in loss
631	of the corresponding resistances (see text). The pRErm46 plasmid of the prototype strain of
632	the MDR 2287 clone, PAM 2287, is unique in that it carries one of its three TnRErm46
633	copies inserted within the C1I's <i>aadA9</i> (streptomycin/spectinoycin resistance) cassette (35).
634	This insertion does not affect tetracycline resistance despite abolishing sul1-mediated
635	sulfonamide resistance, indicating that the IS6100-flanked tetRA(33) determinant is
636	expressed independently of the integron's promoter that drives the expression of C1I's
637	aadA9 and sul1 cassettes (Pc). The gene markers for PCR detection of pRErm46's backbone
638	(Table 3), and the position of the oligonucleotide primers for confirmation of the pRErm46
639	deletions (Table S1), are indicated.
