Solar Energy Laboratory

Is established at the Physics Department and has an experience in education and research for 35 years

Activities:

Solar collectors
Photovoltaics
small wind turbines
energy and building greenhouses

ICS Type solar water heaters

Simple and low cost solar water heaters

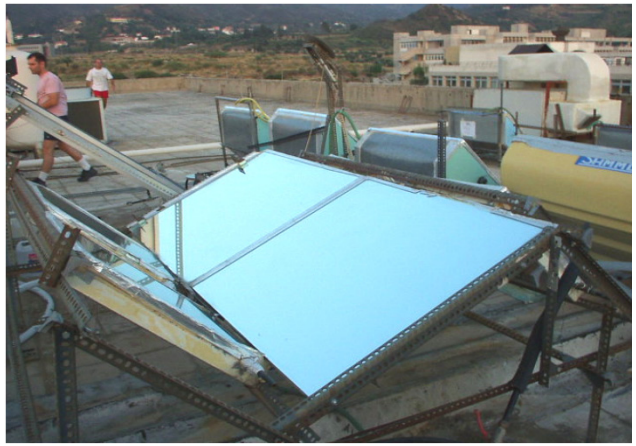
Efficient in water heating

Satisfactory preservation of hot water temperature

Aesthetical integration on buildings

Booster reflectors to improve energy performance

The reflectors increase the solar input achieving higher thermal output at higher operating temperatures.

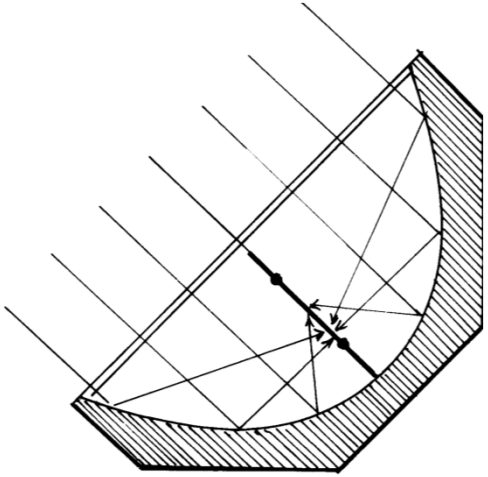


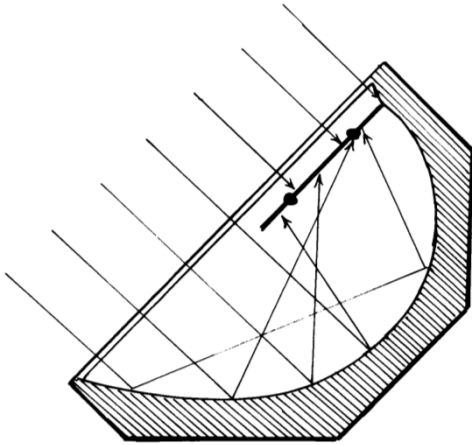
Solar collectors with colored absorbers

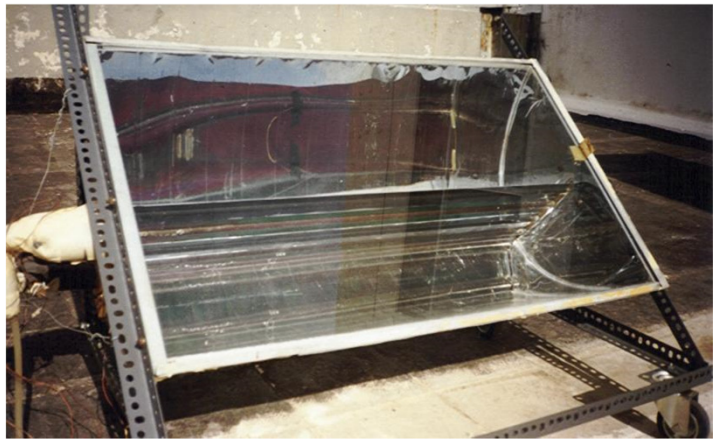
Solar collectors with absorbers of different color than black could be an interesting solution for the wider application of solar energy systems

These collectors are of lower thermal efficiency than that of the usual black collectors because of the lower absorptance

Stationary concentrating CPC solar collectors







Hybrid PV/T Systems

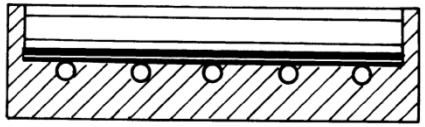
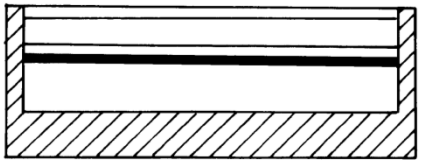
c PV / AIR



b PV / WATER + GL

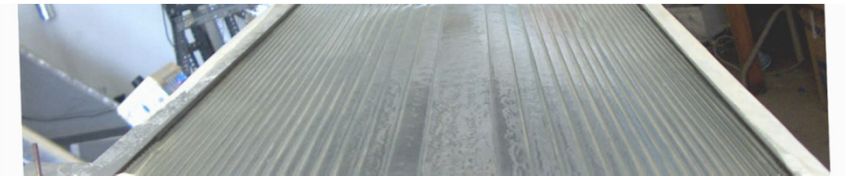


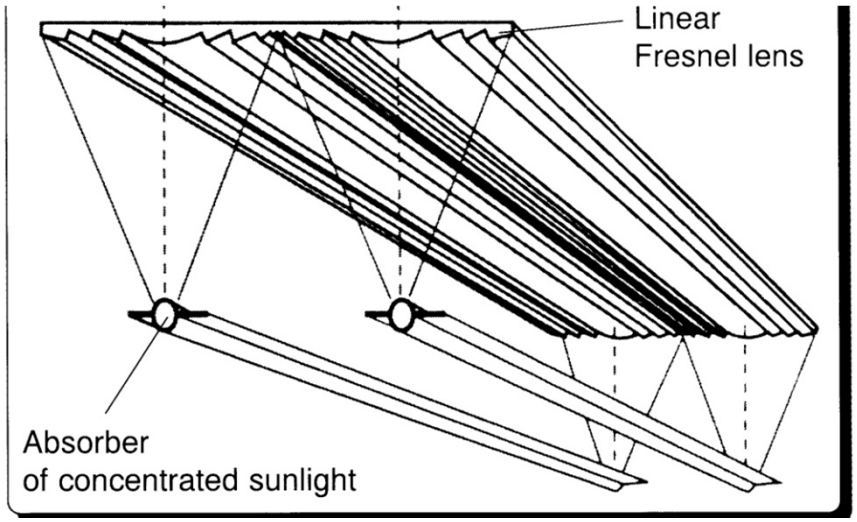
d PV / AIR + GL

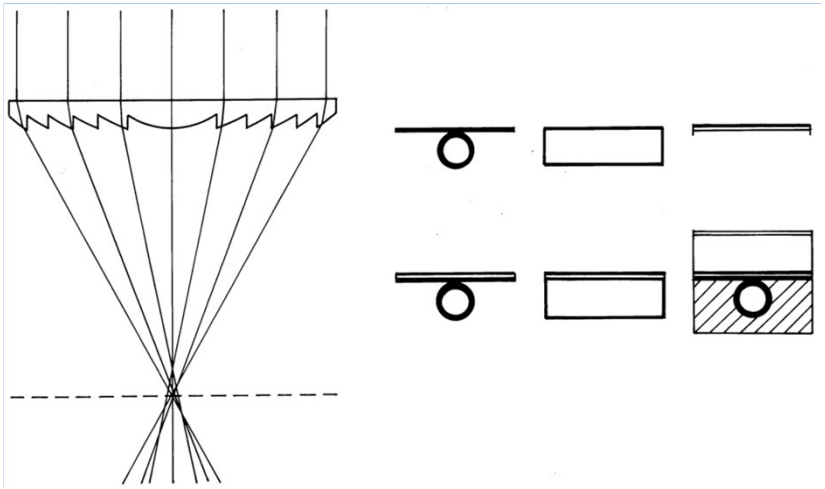
CROSS SECTION OF STUDIED PV/T SYSTEMS

Fresnel lenses for illumination and temperature control

Fresnel lenses are solar radiation concentrators with low volume and weight and low cost. They can separate the direct from the diffuse solar radiation and it makes them suitable for illumination control in the building interior space, providing light without sharp contrasts.



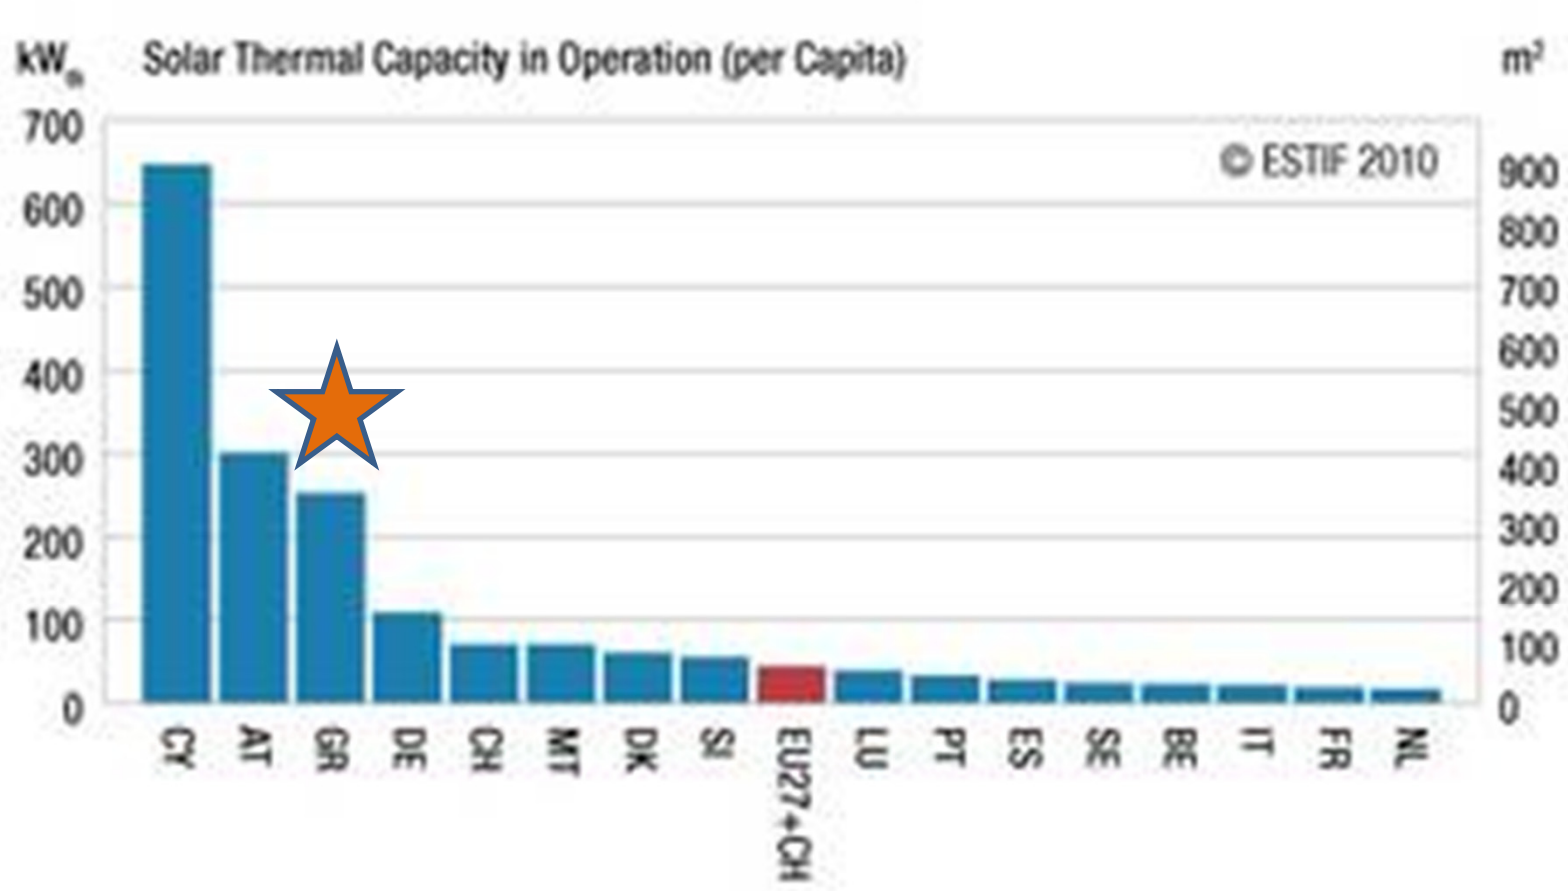




The surplus solar energy can be extracted and used to cover building electrical and thermal needs.

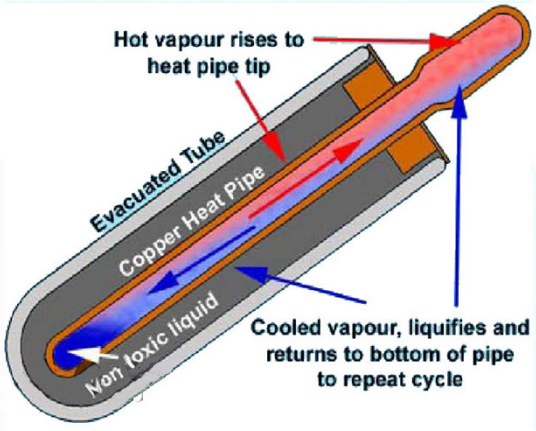
Solar Thermal

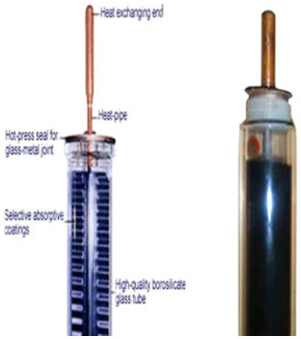
Domestic Hot Water



Installed solar thermal collectors per capita

Flat plate collector, vacuum collector, thermosiphonic collector, parabolic trough, Fresnel reflector and Fresnel lens concentrating collector.





Solar Thermal systems

Application examples of solar thermal collectors

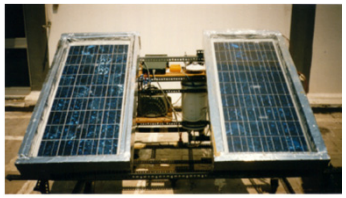
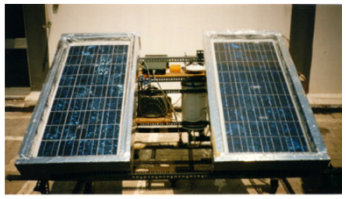
Hybrid Photovoltaic/Thermal solar systems

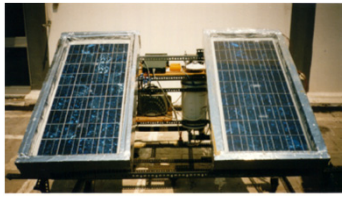
The hybrid Photovoltaic/Thermal (PV/T) solar collectors are consisted of mounted together photovoltaic panels and thermal units that extract the heat and provide simultaneously electricity and heat.

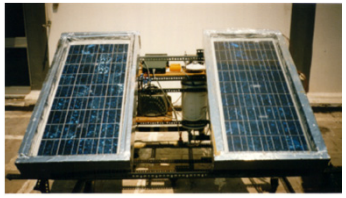
Thermal collectors and Photovoltaics separately installed on building roof

Concept of Hybrid Photovoltaic/Thermal solar systems









Photovoltaics convert 5%-15% (depending on the technology) of the solar radiation into electricity and the rest is converted into heat.

The heat inctreses the temperature of PV modules and this results to electrical efficiency drop.

This effect can be partially avoided by applying a suitable heat extraction mode

The PV modules combined with thermal units consist the hybrid Photovoltaic/Thermal (PV/T) systems providing electrical and thermal output.

PV/T systems provide simultaneously electricity (5%-15%) and heat (50%-70%).

Hybrid Photovoltaic/Thermal Solar Energy Systems installed on buildings

Aspects for Hybrid Photovoltaic/Thermal systems

Air-cooled PV modules (PVT/AIR systems) can cover building heating and ventilation needs.

Water-cooled PV modules (PVT/WATER systems) are used for water heating, space heating, etc.

PV/T solar collectors integrated on buildings can replace the thermal collectors and photovoltaics

In PV/T collectors the electrical and thermal efficiencies depend on PV temperature

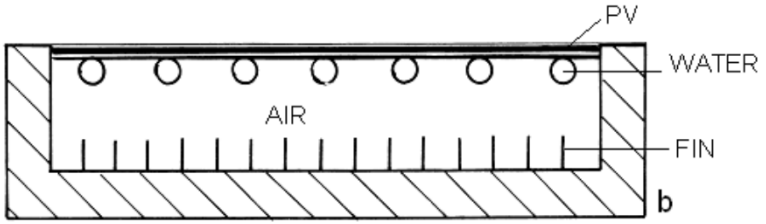
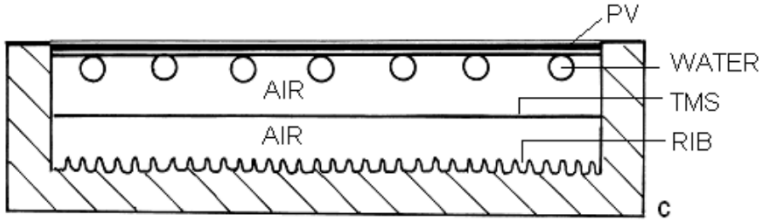
TMS



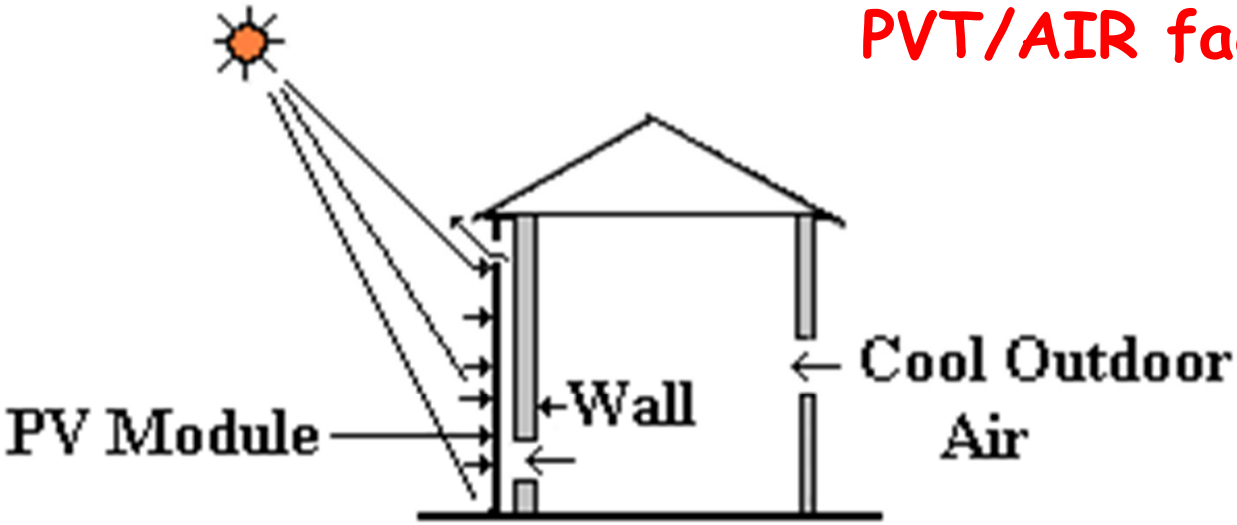
FIN



TMS/RIB

This system can operate either with water or with air heat extraction, according the weather conditions and the energy demand of the building

PVT/AIR façade integration

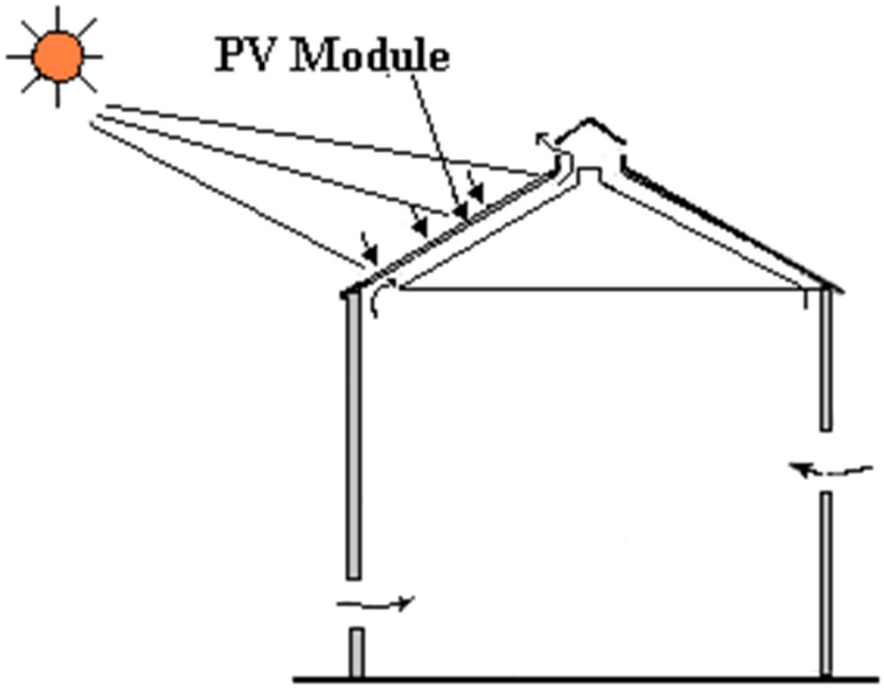


PV mounted on Facade for Ventilation

PV modules integrated on the façade with air gap contribute to a heat flow of circulating air out of the building.

Fresh air enters into the building through open windows and doors or infiltration and achieve natural ventilation.

PVT/AIR Roof integration



PV module mounted
as a Solar Roof Ventilator

PV module mounted on the roof operates as a roof solar collector.

Fresh air enters into building through open (or infiltration) windows and doors and achieves natural ventilation.

PV/T system can be used as "ventilation driver" for natural ventilation of building creating substantial ventilation rate with air velocity about 1 ms^{-1}.

TMS "shields" the back wall up to about 3°C below that of REF system and reduces building heat load in summer.

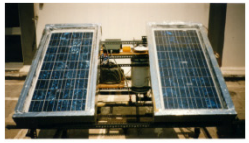
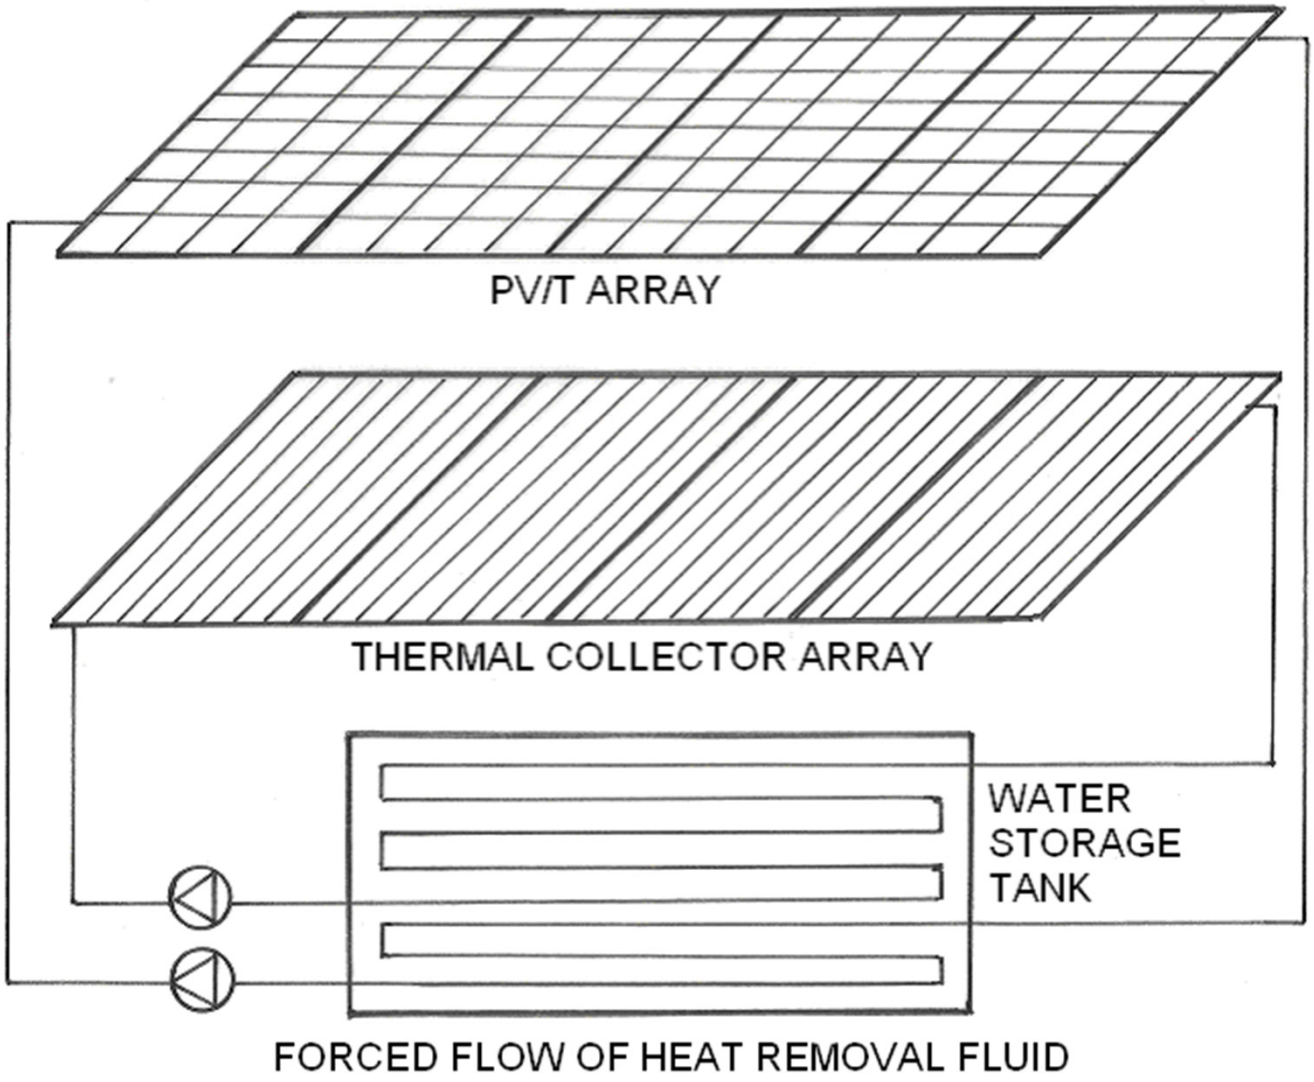
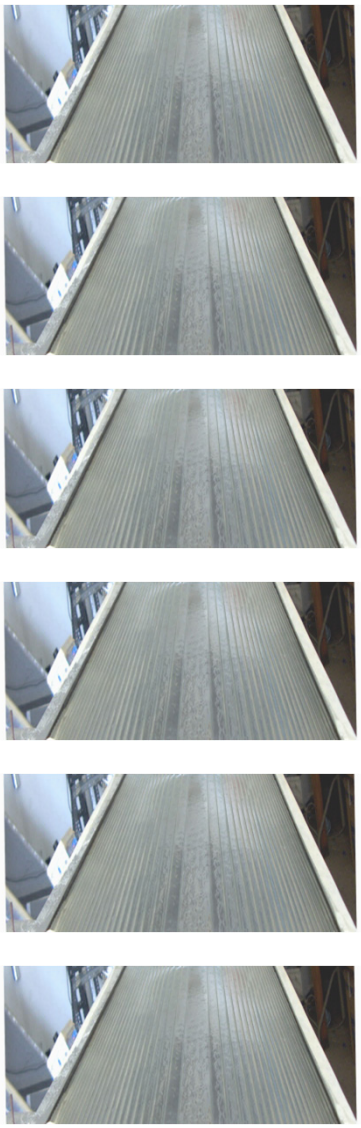
HYBRID PHOTOVOLTAIC/THERMAL SOLAR SYSTEMS



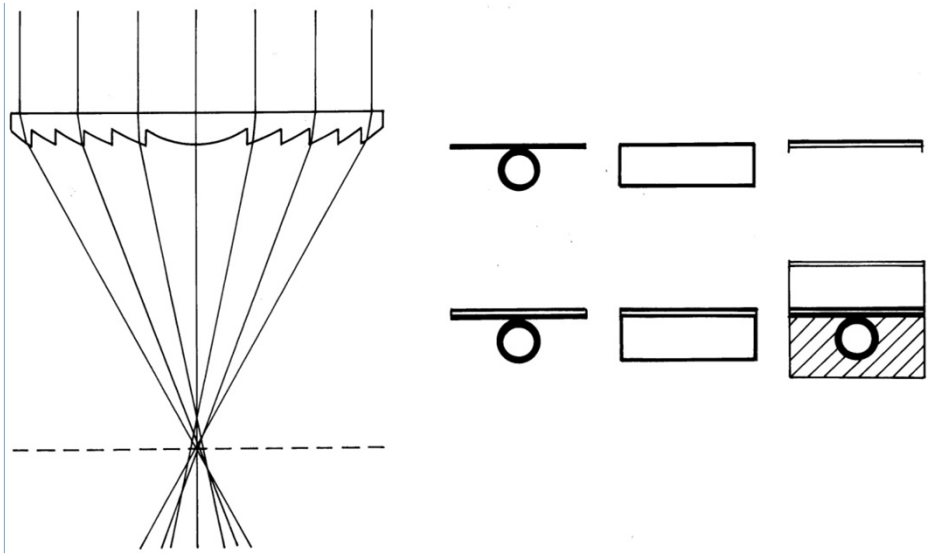


Improved performance with separated thermal collector and PV/T system

PV/T systems combined with Fresnel lenses

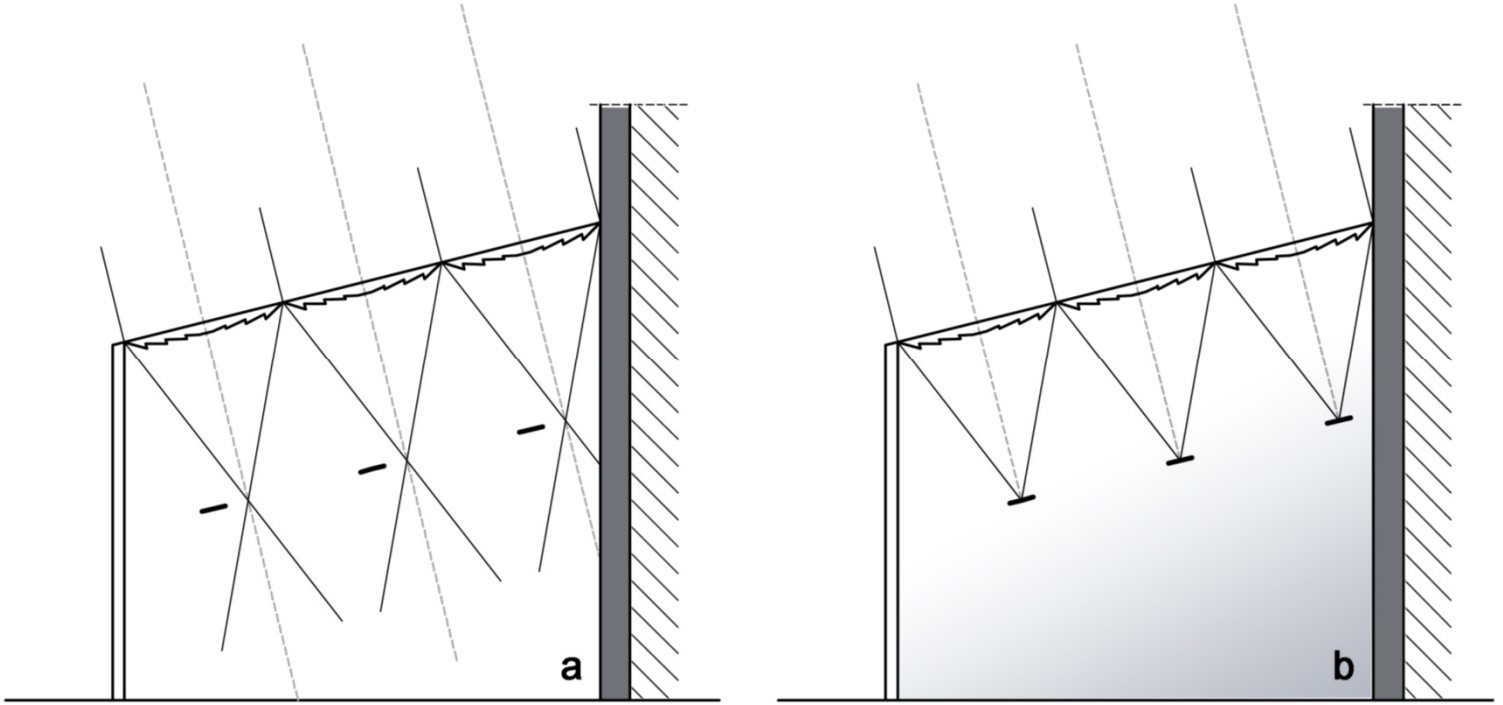


The direct incident solar radiation can be concentrated on an absorber strip, located at the focal position and can be taken away to achieve lower illumination level and also to avoid the overheating of the space.



In low intensity irradiance, the absorber can be out of focus leaving the light to come in the interior space and keep the illumination at an acceptable level.

The operation concept of the fresnel lenses with tracking absorbers



Absorbers out of focus

Absorbers at focus

To control the illumination and the temperature of the transparently covered internal spaces of buildings (atria, sunspaces) the tracking absorbers play a significant role.

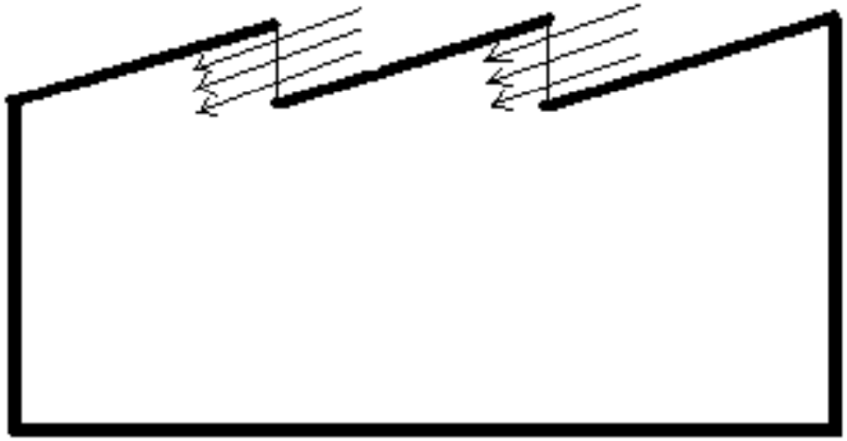
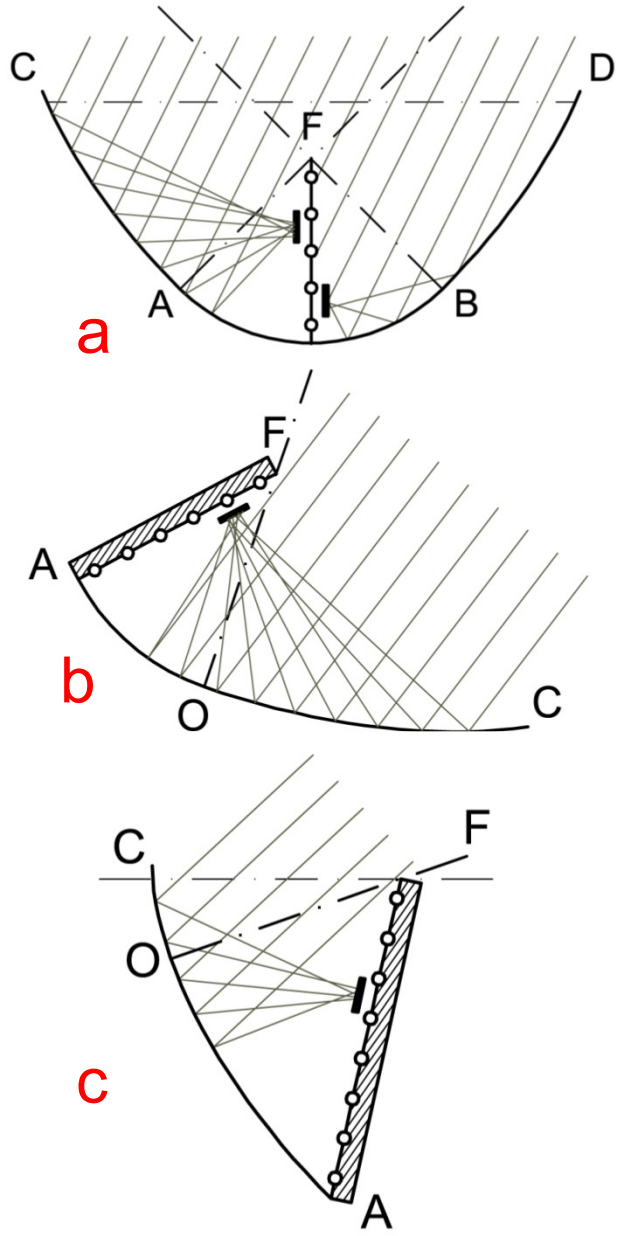
room



industry

CPC reflectors combined with linear PV and PVT absorbers



Stationary CPC reflectors with flat bifacial absorber (a) can be combined with PV strips that track the converged solar radiation and absorb the concentrated solar radiation.

The non-absorbed beam solar radiation and the diffuse solar radiation are absorbed by the flat bifacial thermal absorber and can be taken away by the circulation of a heat removal fluid.

In asymmetric CPC reflector, the PV strip is moving in front of the thermal absorber, tracking the converged solar radiation.

The parabola axis is directed to:
(b) the higher altitude of sun (summer) or to
(c) the lower sun altitude (winter).
