# A mixed formulation for the direct approximation of the control of minimal $L^{2}$-norm for linear type wave equations 

Nicolae Cîndea* Arnaud Münch*

August 23, 2013

#### Abstract

This paper deals with the numerical computation of null controls for the wave equation with a potential. The goal is to compute approximations of controls that drive the solution from a prescribed initial state to zero at a large enough controllability time. In [Cindea, Fernandez-Cara $\xi^{\xi}$ Münch, Numerical controllability of the wave equation through primal methods and Carleman estimates, 2013], a so called primal method is described leading to a strongly convergent approximation of boundary controls : the controls minimize quadratic weighted functionals involving both the control and the state and are obtained by solving the corresponding optimality condition. In this work, we adapt the method to approximate the control of minimal square-integrable norm. The optimality conditions of the problem are reformulated as a mixed formulation involving both the state and his adjoint. We prove the well-posedeness of the mixed formulation (in particular the inf-sup condition) then discuss several numerical experiments. The approach covers both the boundary and the inner controllability. For simplicity, we present the approach in the one dimensional case.

Keywords: Linear wave equation, null controllability, finite element methods, Mixed formulation.

## 1 Introduction. The null controllability problem

We are concerned in this work with the null controllability for the 1 D wave equation with a potential. Let us explain our motivation for the boundary case for which the state equation is the following:

$$
\begin{cases}y_{t t}-\left(c(x) y_{x}\right)_{x}+d(x, t) y=0, & (x, t) \in(0,1) \times(0, T)  \tag{1}\\ y(0, t)=0, \quad y(1, t)=v(t), & t \in(0, T) \\ y(x, 0)=y_{0}(x), \quad y_{t}(x, 0)=y_{1}(x), & x \in(0,1) .\end{cases}
$$

Here, $T>0$ and we assume that $c \in C^{3}([0,1])$ with $c(x) \geq c_{0}>0$ in $[0,1], d \in L^{\infty}((0,1) \times$ $(0, T)), y_{0} \in L^{2}(0,1)$ and $y_{1} \in H^{-1}(0,1) ; v=v(t)$ is the control (a function in $\left.L^{2}(0, T)\right)$ and $y=y(x, t)$ is the associated state.

In the sequel, for any $\tau>0$ we denote by $Q_{\tau}$ and $\Sigma_{\tau}$ the sets $(0,1) \times(0, \tau)$ and $\{0,1\} \times(0, \tau)$, respectively. We also use the following notation:

$$
\begin{equation*}
L y:=y_{t t}-\left(c(x) y_{x}\right)_{x}+d(x, t) y . \tag{2}
\end{equation*}
$$

For any $\left(y_{0}, y_{1}\right) \in \boldsymbol{Y}:=L^{2}(0,1) \times H^{-1}(0,1)$ and any $v \in L^{2}(0, T)$, there exists exactly one solution $y$ to (1), with the following regularity:

$$
\begin{equation*}
y \in C^{0}\left([0, T] ; L^{2}(0,1)\right) \cap C^{1}\left([0, T] ; H^{-1}(0,1)\right) \tag{3}
\end{equation*}
$$

(see for instance [27]). The null controllability problem for (1] at time $T$ is the following: for each $\left(y_{0}, y_{1}\right) \in \boldsymbol{Y}$, find $v \in L^{2}(0, T)$ such that the corresponding solution to (1) satisfies

$$
\begin{equation*}
y(\cdot, T)=0, \quad y_{t}(\cdot, T)=0 \quad \text { in } \quad(0,1) \tag{4}
\end{equation*}
$$

It is well known that (11) is null-controllable at any large time $T>T^{\star}$ for some $T^{\star}$ that depends on $c$ (for instance, see [2, 27] for $c \equiv 1$ and $d \equiv 0$ leading to $T^{\star}=2$ and see [33 for a general situation). Moreover, as a consequence of the Hilbert Uniqueness Method of J.-L. Lions [27], the null controllability of (1) is equivalent to an observability inequality for the associated adjoint problem.

In the last two decades, a large number of works has been concerned with the (numerical) approximation of null controls for wave type equations. Since controllability holds in $L^{2}$, the approximation of the minimal $L^{2}$-norm control (refereed by some authors as the HUM control) has focused most of the attention : the problem reads

$$
\left\{\begin{array}{l}
\text { Minimize } \quad J(y, v)=\frac{1}{2} \int_{0}^{T}|v(t)|^{2} d t  \tag{5}\\
\text { Subject to } \quad(y, v) \in \mathcal{C}\left(y_{0}, y_{1} ; T\right)
\end{array}\right.
$$

where $\mathcal{C}\left(y_{0}, y_{1} ; T\right)$ denotes the linear manifold

$$
\mathcal{C}\left(y_{0}, y_{1} ; T\right)=\left\{(y, v): v \in L^{2}(0, T), y \text { solves (1) and satisfies (4) }\right\} \text {. }
$$

The earlier contribution is due to Glowinski and Lions in 19 (updated in [20) and relies on duality arguments. Duality allows to replace the original constrained minimization problem by an
unconstrained and a priori easier minimization (dual) problem. We define $\boldsymbol{V}=H_{0}^{1}(0,1) \times L^{2}(0,1)$. The dual problem associated with (5) is :

$$
\begin{equation*}
\min _{\left(\varphi_{0}, \varphi_{1}\right) \in \boldsymbol{V}} J^{\star}\left(\varphi_{0}, \varphi_{1}\right)=\frac{1}{2} \int_{0}^{T}\left|c(1) \varphi_{x}(1, t)\right|^{2} d t+\int_{0}^{1} y_{0}(x) \varphi_{t}(x, 0) d x-\left\langle y_{1}, \varphi(\cdot, 0)\right\rangle_{H^{-1}, H_{0}^{1}} \tag{6}
\end{equation*}
$$

where the variable $\varphi$ solves the backward wave equation :

$$
\begin{equation*}
L \varphi=0 \quad \text { in } \quad Q_{T}, \quad \varphi=0 \quad \text { on } \quad \Sigma_{T} ; \quad\left(\varphi(\cdot, T), \varphi_{t}(\cdot, T)\right)=\left(\varphi_{0}, \varphi_{1}\right) \tag{7}
\end{equation*}
$$

The coercivity of $J^{\star}$ - called the conjugate functional of $J$ - is the consequence of the following estimate : there exists $k_{T}>0$ such that

$$
\begin{equation*}
\left\|\varphi(\cdot, 0), \varphi_{t}(\cdot, 0)\right\|_{V}^{2} \leq k_{T}\left\|c(1) \varphi_{x}(1, \cdot)\right\|_{L^{2}(0, T)}^{2}, \quad \forall\left(\varphi_{0}, \varphi_{1}\right) \in \boldsymbol{V} \tag{8}
\end{equation*}
$$

where $\left(\varphi_{0}, \varphi_{1}, \varphi\right)$ solves (7). This estimate, refereed in the literature as an observability inequality, holds true if $T$ is large enough.

At the level of the approximation, the minimization of $J^{\star}$ requires to find a finite dimensional and conformal approximation of $\boldsymbol{V}$ such that the corresponding discrete adjoint solution satisfies (7), which is in general impossible for polynomial piecewise approximation. In practice, the trick initially described in [19], consists first to introduce a discrete and consistent approximation of (1) and then minimize the corresponding discrete conjugate functional. But this requires to prove uniform discrete observability inequalities that turn out to be not satisfied when very standard approximations (for instance based on finite differences on uniform meshes) are used. This is due to some spurious high frequencies components generated by the approximation which can not be controlled in a uniform time (with respect to the discretization parameters). This observation has raised many developments in order to get so-called uniform observable (or equivalently controllable) approximation. We mention the references [8, 15, 21, 22, 24, 28, 30 and we refer to [1, 4, 26] for some numerical realizations in 2D based on spectral methods. As far as we know, the determination of discrete observability inequalities is still open in the general case (non uniform mesh, wave equation with non constant coefficient, etc).

In contrast to these works where solutions of the discrete wave equations are exactly controlled to zero, we mention [12, 31 based on Russell's approach where convergent approximations of an exact control (not necessarily the HUM control) are build.

In [11, a different - so-called primal approach - allowing more general results has been used and consists to solve directly optimality conditions: specifically, the following general extremal problem is considered

$$
\left\{\begin{array}{l}
\text { Minimize } J(y, v)=\frac{1}{2} \iint_{Q_{T}} \rho^{2}|y|^{2} d x d t+\frac{1}{2} \int_{0}^{T} \rho_{0}^{2}|v|^{2} d t  \tag{9}\\
\text { Subject to }(y, v) \in \mathcal{C}\left(y_{0}, y_{1} ; T\right)
\end{array}\right.
$$

The weights $\rho$ and $\rho_{0}$ are strictly positive, continuous and uniformly bounded from below by a positive constant in $Q_{T}$ and $(0, T)$, respectively. For $c$ in the class $\mathcal{A}\left(x_{0}, c_{0}\right)$ and $T$ large enough, greater than $T^{\star}(c)$ (both defined in Section 2 ), the extremal problem (9) is well-posed. Moreover, defining the Hilbert space $P$ as the completion of the linear space $P_{0}=\left\{q \in C^{\infty}\left(\overline{Q_{T}}\right): q=\right.$ 0 on $\left.\Sigma_{T}\right\}$ with respect to the scalar product

$$
\begin{equation*}
(p, q)_{P}:=\iint_{Q_{T}} \rho^{-2} L p L q d x d t+\int_{0}^{T} \rho_{0}^{-2} c(1)^{2} p_{x}(1, t) q_{x}(1, t) d t \tag{10}
\end{equation*}
$$

we may obtain the following characterization of the optimal pair $(y, v)$ in term of an additional variable $p \in P$ as follows:

$$
\begin{equation*}
y=-\rho^{-2} L p \quad \text { in } \quad Q_{T}, \quad v=-\left.\left(c(x) \rho_{0}^{-2} p_{x}\right)\right|_{x=1} \quad \text { in } \quad(0, T) \tag{11}
\end{equation*}
$$

$p \in P$ is the unique solution to the following variational equality:

$$
\begin{equation*}
(p, q)_{P}=\int_{0}^{1} y_{0}(x) q_{t}(x, 0) d x-\left\langle y^{1}, q(\cdot, 0)\right\rangle_{H^{-1}, H_{0}^{1}}, \quad \forall q \in P \tag{12}
\end{equation*}
$$

Here and in the sequel, we use the following duality pairing:

$$
\left\langle y^{1}, q(\cdot, 0)\right\rangle_{H^{-1}, H_{0}^{1}}=\int_{0}^{1} \frac{\partial}{\partial x}\left((-\Delta)^{-1} y_{1}\right)(x) q_{x}(x, 0) d x
$$

where $-\Delta$ is the Dirichlet Laplacian in $(0,1)$. We refer the reader to 11 for the details. The search of a control $v$ in the manifold $\mathcal{C}\left(y_{0}, y_{1}, T\right)$ is reduced to solve the (elliptic) variational formulation (12). The approximation of the solution of 12 is performed in the framework of the finite element theory through a discretization of the space-time domain $Q_{T}$. In practice, an approximation $p_{h}$ of $p$ is obtained in a direct way by inverting a symmetric positive definite matrix, in contrast with the iterative (and possibly divergent) methods used within dual methods. Moreover, a major advantage of this approach is that a conformal approximation, say $P_{h}$ of $P$, leads to the strong convergence of $p_{h}$ toward $p$ in $P$, and consequently from 11, to a strong convergence in $L^{2}$ of $v_{h}:=-\left.\left(c(x) \rho_{0}^{-2} p_{h, x}\right)\right|_{x=1}$ toward $v$, a null control for (1). It is worth to mention that, for any $h>0$, as in the works [12, 31] mentioned earlier, $v_{h}$ is not a priori an exact control for any finite dimensional system but an approximation for the $L^{2}$-norm of the control $v$.

The variational formulation 12 derived from the optimality conditions 11 is obtained assuming that the weights $\rho$ and $\rho_{0}$ are strictly positive in $Q_{T}$ and $(0, T)$ respectively. In particular, this approach does not apply for the control of minimal $L^{2}$-norm, for which simply $\rho:=0$ and $\rho_{0}:=1$. The main reason of the present work is to adapt this approach to cover the case $\rho:=0$ and therefore obtain directly a strong convergent approximation $v_{h}$ of the control of minimal $L^{2}$-norm.

The paper is organized as follows. In Section 2, we recall the definition of the admissible set $\mathcal{A}\left(x_{0}, c_{0}\right)$ for the function $c$ and of the minimal time $T^{\star}(c)$ determined in 11 then we associate to the dual problem (6) an equivalent mixed formulation which relies on the optimality conditions associated to the problem (5). We then show the well-posedness of this mixed formulation, in particular we check the inf-sup condition. The mixed formulation allows to approximate simultaneously the dual variable and the primal one, controlled solution of (1). Interestingly, we also derive an extremal problem in the primal variable $y$ only. Section 3 is devoted to the distributed case for which the strategy also applies. Section 4 is devoted to the numerical approximation of the mixed formulation as well as numerical experiments, both in the boundary and inner case. Eventually, Section 5 concludes with some perspectives : in particular, we highlight that the variational approach is very appropriate to consider inner control distributed on time dependent support, an issue recently considered in [6].

## 2 Control of minimal $L^{2}$-norm: a mixed reformulation

We present in this section a mixed formulation based on the optimality conditions associated to the extremal problem (5). The starting point is the dual problem recalled in the introduction. Preliminary, we precise the minimal controllability time $T^{\star}$.

We introduce the set

$$
\begin{align*}
\mathcal{A}\left(x_{0}, c_{0}\right) & =\left\{c \in C^{3}([0,1]): c(x) \geq c_{0}>0\right.  \tag{13}\\
& \left.-\min _{[0,1]}\left(c(x)+\left(x-x_{0}\right) c_{x}(x)\right)<\min _{[0,1]}\left(c(x)+\frac{1}{2}\left(x-x_{0}\right) c_{x}(x)\right)\right\}
\end{align*}
$$

where $x_{0}<0$ and $c_{0}$ is a positive constant. This set is non empty and contains in particular the constant function $c:=c_{0}$. The following result holds.

Proposition 2.1 ([11]) Let us assume that $x_{0}<0, c_{0}>0$ and $c \in \mathcal{A}\left(x_{0}, c_{0}\right)$. Let $\beta>0$ be a positive number with

$$
-\min _{[0,1]}\left(c(x)+\left(x-x_{0}\right) c_{x}(x)\right)<\beta<\min _{[0,1]}\left(c(x)+\frac{1}{2}\left(x-x_{0}\right) c_{x}(x)\right)
$$

and let us consider the function $\phi(x, t):=\left|x-x_{0}\right|^{2}-\beta t^{2}+M_{0}$ where $M_{0}$ is such that $\phi(x, t) \geq 1$ for all $(x, t) \in(0,1) \times(-T, T)$. Then, for any $\lambda>0$ we set $g(x, t):=e^{\lambda \phi(x, t)}$. Finally, let us assume that

$$
\begin{equation*}
T>\frac{1}{\beta} \max _{[0,1]} c(x)^{1 / 2}\left(x-x_{0}\right) \tag{14}
\end{equation*}
$$

Then there exist positive constants $s_{0}$ and $M$, only depending on $x_{0}, c_{0},\|c\|_{C^{3}([0,1])},\|d\|_{L^{\infty}\left(Q_{T}\right)}$ and $T$, such that, for all $s>s_{0}$, one has

$$
\begin{align*}
& s \int_{-T}^{T} \int_{0}^{1} e^{2 s g}\left(\left|w_{t}\right|^{2}+\left|w_{x}\right|^{2}\right) d x d t+s^{3} \int_{-T}^{T} \int_{0}^{1} e^{2 s g}|w|^{2} d x d t \\
& \quad \leq M \int_{-T}^{T} \int_{0}^{1} e^{2 s g}|L w|^{2} d x d t+M s \int_{-T}^{T} e^{2 s g}\left|w_{x}(1, t)\right|^{2} d t \tag{15}
\end{align*}
$$

for any $w \in L^{2}\left(-T, T ; H_{0}^{1}(0,1)\right)$ satisfying $L w \in L^{2}((0,1) \times(-T, T))$ and $w_{x}(1, \cdot) \in L^{2}(-T, T)$.
Then, for any $c \in \mathcal{A}\left(x_{0}, c_{0}\right)$, we define $T^{\star}(c)$ as follows :

$$
\begin{equation*}
T^{\star}(c):=\frac{2}{\beta} \max _{[0,1]} c(x)^{1 / 2}\left(x-x_{0}\right) \tag{16}
\end{equation*}
$$

with $\beta$ as in Proposition 2.1.
Proposition 2.1 allows to show in particular that for any $c \in \mathcal{A}$ and any $T>T^{\star}(c)$, there exists a positive constant $k_{T}=k_{T}(c)$ such that the estimate 8 holds. We refer to [11] for details. The minimization of $J^{\star}$ is then well-posed and if $\left(\hat{\varphi}_{0}, \hat{\varphi}_{1}\right)$ denotes the minimizer of $J^{\star}$, the control of minimal $L^{2}$-norm is given by

$$
\begin{equation*}
v=c(1) \hat{\varphi}_{x}(1, \cdot) \quad \text { in } \quad(0, T) \tag{17}
\end{equation*}
$$

The extremal problem $\min _{\left(\varphi_{0}, \varphi_{1}\right) \in \boldsymbol{V}} J^{\star}\left(\varphi_{0}, \varphi_{1}\right)$ is usually called the dual problem associated to (5).
Remark 1 The inequality (8) can also be obtained directly by the multiplier method (see [33]) and requires $T$ to be large enough. Note that, when $c(x) \equiv c_{0}$, the assumption (14) simply reads $T>\frac{2\left(1-x_{0}\right)}{\sqrt{c_{0}}}>\frac{2}{\sqrt{c_{0}}}$ which is optimal.

### 2.1 Mixed reformulation of the controllability problem

In order to avoid the minimization of the functional $J^{\star}$ with respect to the initial data $\left(\varphi_{0}, \varphi_{1}\right)$, we now present a direct way to approximate the HUM control, in the spirit of the primal approach recalled in the introduction and developed in 11.

Since the variable $\varphi$, solution of $(7)$, is completely and uniquely determined by the data $\left(\varphi_{0}, \varphi_{1}\right)$, the main idea of the reformulation is to keep $\varphi$ as main variable and consider the following extremal problem:

$$
\begin{equation*}
\min _{\varphi \in W} \hat{J}^{\star}(\varphi)=\frac{1}{2} \int_{0}^{T}\left|c(1) \varphi_{x}(1, t)\right|^{2} d t+\int_{0}^{1} y_{0}(x) \varphi_{t}(x, 0) d x-\left\langle y_{1}, \varphi(\cdot, 0)\right\rangle_{H^{-1}, H_{0}^{1}} \tag{18}
\end{equation*}
$$

where

$$
W=\left\{\varphi \in L^{2}\left(Q_{T}\right), \varphi=0 \text { on } \Sigma_{T} \text { such that } L \varphi=0 \in L^{2}\left(Q_{T}\right) \text { and } \varphi_{x}(1, \cdot) \in L^{2}(0, T)\right\}
$$

$W$ is an Hilbert space endowed with the inner product

$$
(\varphi, \bar{\varphi})_{W}=\int_{0}^{T} c(1) \varphi_{x}(1, t) \bar{\varphi}_{x}(1, t) d t+\eta \iint_{Q_{T}} L \varphi L \bar{\varphi} d x d t, \quad \forall \varphi, \bar{\varphi} \in W
$$

for any fixed $\eta>0$. We denote $\|\cdot\|_{W}$ the associated norm such that

$$
\begin{equation*}
\|\varphi\|_{W}^{2}=\int_{0}^{T}\left|c(1) \varphi_{x}(1, t)\right|^{2} d t+\eta\|L \varphi\|_{L^{2}\left(Q_{T}\right)}^{2}, \quad \forall \varphi \in W \tag{19}
\end{equation*}
$$

The minimization of $\hat{J}^{\star}$ is evidently equivalent to the minimization of $J^{\star}$ over $\boldsymbol{V}$. Remark that from (8) the property $\varphi \in W$ implies that $\left(\varphi(\cdot, 0), \varphi_{t}(\cdot, 0)\right) \in \boldsymbol{V}$, so that the functional $\hat{J}^{\star}$ is well-defined over $W$.

The main variable is now $\varphi$ submitted to the constraint equality (in $\left.L^{2}\left(Q_{T}\right)\right) L \varphi=0$. This constraint is addressed by introducing a mixed formulation. We define the space $\Phi$ larger than $W$ by

$$
\Phi=\left\{\varphi \in L^{2}\left(Q_{T}\right), \varphi=0 \text { on } \Sigma_{T} \text { such that } L \varphi \in L^{2}\left(Q_{T}\right) \text { and } \varphi_{x}(1, \cdot) \in L^{2}(0, T)\right\}
$$

$\Phi$ is endowed with the same norm than $W$.
Then, we consider the following mixed formulation : find $(\varphi, \lambda) \in \Phi \times L^{2}\left(Q_{T}\right)$ solution of

$$
\left\{\begin{align*}
a(\varphi, \bar{\varphi})+b(\bar{\varphi}, \lambda) & =l(\bar{\varphi}), & & \forall \bar{\varphi} \in \Phi  \tag{20}\\
b(\varphi, \bar{\lambda}) & =0, & & \forall \bar{\lambda} \in L^{2}\left(Q_{T}\right)
\end{align*}\right.
$$

where

$$
\begin{align*}
a: \Phi \times \Phi & \rightarrow \mathbb{R}, \quad a(\varphi, \bar{\varphi})=\int_{0}^{T} c(1) \varphi_{x}(1, t) \bar{\varphi}_{x}(1, t) d t  \tag{21}\\
b: \Phi \times L^{2}\left(Q_{T}\right) & \rightarrow \mathbb{R}, \quad b(\varphi, \lambda)=\iint_{Q_{T}} L \varphi(x, t) \lambda(x, t) d x d t  \tag{22}\\
l: \Phi & \rightarrow \mathbb{R}, \quad l(\varphi)=-\int_{0}^{1} y_{0}(x) \varphi_{t}(x, 0) d x+\left\langle y_{1}, \varphi(\cdot, 0)\right\rangle_{H^{-1}, H_{0}^{1}} \tag{23}
\end{align*}
$$

We have the following result :
ThEOREM 2.1 (i) The mixed formulation 20 is well-posed.
(ii) The unique solution $(\varphi, \lambda) \in \Phi \times L^{2}\left(Q_{T}\right)$ is the unique saddle-point of the Lagrangian $\mathcal{L}: \Phi \times L^{2}\left(Q_{T}\right) \rightarrow \mathbb{R}$ defined by

$$
\begin{equation*}
\mathcal{L}(\varphi, \lambda)=\frac{1}{2} a(\varphi, \varphi)+b(\varphi, \lambda)-l(\varphi) \tag{24}
\end{equation*}
$$

(iii) The optimal function $\varphi$ is the minimizer of $\hat{J}^{\star}$ over $\Phi$ while the optimal function $\lambda \in L^{2}\left(Q_{T}\right)$ is the state of the controlled wave equation (1) in the weak sense.
Proof - We easily check that the bilinear form $a$ is continuous over $\Phi \times \Phi$, symmetric and positive and that the bilinear form $b$ is continuous over $\Phi \times L^{2}\left(Q_{T}\right)$. Furthermore, assuming $c \in \mathcal{A}$ and $T>T^{\star}(c)$, the continuity of the linear form $l$ over $\Phi$ is a direct consequence of the Carleman estimate (15) given by Proposition 2.1. Precisely, using the fact that the weight $e^{2 g s}$ (see 15 ) is bounded and uniformly positive, we deduce from that there exists a constant $C_{0}>0$ such that

$$
\begin{equation*}
\left\|\varphi(\cdot, 0), \varphi_{t}(\cdot, 0)\right\|_{H_{0}^{1} \times L^{2}}^{2} \leq C_{0}\left(\|L \varphi\|_{L^{2}\left(Q_{T}\right)}^{2}+\left\|c(1) \varphi_{x}(1, \cdot)\right\|_{L^{2}(0, T)}^{2}\right), \quad \forall \varphi \in \Phi \tag{25}
\end{equation*}
$$

Therefore, the well-posedness of the mixed formulation is a consequence of the following two properties (see [5]):

- $a$ is coercive on $\mathcal{N}(b)$, where $\mathcal{N}(b)$ denotes the kernel of $b$ :

$$
\mathcal{N}(b)=\left\{\varphi \in \Phi \text { such that } b(\varphi, \lambda)=0 \text { for every } \lambda \in L^{2}\left(Q_{T}\right)\right\}
$$

- $b$ satisfies the usual "inf-sup" condition over $\Phi \times L^{2}\left(Q_{T}\right)$ : there exists $\delta>0$ such that

$$
\begin{equation*}
\inf _{\lambda \in L^{2}\left(Q_{T}\right)} \sup _{\varphi \in \Phi} \frac{b(\varphi, \lambda)}{\|\varphi\|_{\Phi}\|\lambda\|_{L^{2}\left(Q_{T}\right)}} \geq \delta \tag{26}
\end{equation*}
$$

From the definition of $a$, the first point is clear : for all $\varphi \in \mathcal{N}(b)=W, a(\varphi, \varphi)=\|\varphi\|_{W}^{2}$. Let us check the inf-sup condition. For any fixed $\lambda_{0} \in L^{2}\left(Q_{T}\right)$, we define the (unique) element $\varphi_{0}$ such that $L \varphi_{0}=\lambda_{0}$ and such that $\varphi(\cdot, 0)=0$ in $H_{0}^{1}(0,1)$ and $\varphi_{t}(\cdot, 0)=0$ in $L^{2}(0,1) . \varphi_{0}$ is therefore solution of the wave equation with source term $\lambda_{0} \in L^{2}\left(Q_{T}\right)$, null Dirichlet boundary condition and zero initial state. Since $\lambda_{0} \in L^{2}\left(Q_{T}\right)$, then $\varphi_{0, x}(1, \cdot) \in L^{2}(0, T)$ : precisely, using the multipliers method (see, for instance, Chapter 1 in [27]), there exists a constant $C_{\Omega, T}>0$ such that the solution $\varphi_{0}$ of the wave equation with source term $\lambda_{0}$ satisfies the so-called direct equality

$$
\begin{equation*}
\int_{0}^{T}\left|c(1) \varphi_{0, x}(1, t)\right|^{2} d t \leq C_{\Omega, T} c^{2}(1)\left\|\lambda_{0}\right\|_{L^{2}\left(Q_{T}\right)}^{2} \tag{27}
\end{equation*}
$$

Consequently, $\varphi_{0} \in \Phi$. In particular, we have $b\left(\varphi_{0}, \lambda_{0}\right)=\left\|\lambda_{0}\right\|_{L^{2}\left(Q_{T}\right)}^{2}$ and

$$
\sup _{\varphi \in \Phi} \frac{b\left(\varphi, \lambda_{0}\right)}{\|\varphi\|_{\Phi}\left\|\lambda_{0}\right\|_{L^{2}\left(Q_{T}\right)}} \geq \frac{b\left(\varphi_{0}, \lambda_{0}\right)}{\left\|\varphi_{0}\right\|_{\Phi}\left\|\lambda_{0}\right\|_{L^{2}\left(Q_{T}\right)}}=\frac{\|\lambda\|_{L^{2}\left(Q_{T}\right)}^{2}}{\left(\int_{0}^{T}\left|c(1) \varphi_{x}(1, t)\right|^{2} d t+\eta\left\|\lambda_{0}\right\|_{L^{2}\left(Q_{T}\right)}^{2}\right)^{\frac{1}{2}}\left\|\lambda_{0}\right\|_{L^{2}\left(Q_{T}\right)}}
$$

Combining the above two inequalities, we obtain

$$
\sup _{\varphi_{0} \in \Phi} \frac{b\left(\varphi_{0}, \lambda_{0}\right)}{\left\|\varphi_{0}\right\|_{\Phi}\left\|\lambda_{0}\right\|_{L^{2}\left(Q_{T}\right)}} \geq \frac{1}{\sqrt{C_{\Omega, T} c^{2}(1)+\eta}}
$$

and, hence, 26 holds with $\delta=\left(C_{\Omega, T} c^{2}(1)+\eta\right)^{-\frac{1}{2}}$.
The point (ii) is due to the symmetry and to the positivity of the bilinear form $a$. (iii). The equality $b(\varphi, \lambda)=0$ for all $\lambda \in L^{2}\left(Q_{T}\right)$ implies that $L \varphi=0$ as an $L^{2}\left(Q_{T}\right)$ function, so that if $(\varphi, \lambda) \in \Phi \times L^{2}\left(Q_{T}\right)$ solves the mixed formulation, then $\varphi \in W$ and $\mathcal{L}(\varphi, \lambda)=\hat{J}^{\star}(\varphi)$. Finally, the first equation of the mixed formulation reads as follows :

$$
\int_{0}^{T} c(1) \varphi_{x}(1, t) \bar{\varphi}_{x}(1, t) d t+\iint_{Q_{T}} L \bar{\varphi}(x, t) \lambda(x, t) d x d t=l(\bar{\varphi}), \quad \forall \bar{\varphi} \in \Phi
$$

or equivalently, since the control is given by $v=c(1) \varphi_{x}(1, \cdot)$,

$$
\int_{0}^{T} v(t) \bar{\varphi}_{x}(1, t) d t+\iint_{Q_{T}} L \bar{\varphi}(x, t) \lambda(x, t) d x d t=l(\bar{\varphi}), \quad \forall \bar{\varphi} \in \Phi
$$

But this means that $\lambda \in L^{2}\left(Q_{T}\right)$ is solution of the wave equation in the transposition sense. Since $\left(y_{0}, y_{1}\right) \in L^{2}(0,1) \times H^{-1}(0,1)$ and $v \in L^{2}(0, T), \lambda$ must coincide with the unique weak solution to (1).

Therefore, Theorem 2.1 reduces the search of the HUM control to the resolution of the mixed formulation 20, or equivalently the search of the saddle point for $\mathcal{L}$. In general, it is very convenient (actually in the case considered here, it is necessary) to "augment" the Lagrangien (see [17]), and consider instead the Lagrangien $\mathcal{L}_{r}$ defined for any $r>0$ by

$$
\left\{\begin{aligned}
\mathcal{L}_{r}(\varphi, \lambda) & =\frac{1}{2} a_{r}(\varphi, \varphi)+b(\varphi, \lambda)-l(\varphi) \\
a_{r}(\varphi, \varphi) & =a(\varphi, \varphi)+r \iint_{Q_{T}}|L \varphi|^{2} d x d t
\end{aligned}\right.
$$

Since $a(\varphi, \varphi)=a_{r}(\varphi, \varphi)$ on $W$, the lagrangian $\mathcal{L}$ and $\mathcal{L}_{r}$ share the same saddle-point.

### 2.2 Dual problem of the extremal problem (18)

The mixed formulation allows to solve simultaneously the dual variable $\varphi$, argument of the conjugate functional 18, and the Lagrange multiplier $\lambda$. Since $\lambda$ turns out to be the controlled state of (1), we may qualify $\lambda$ as the primal variable of the problem. We derive in this section the corresponding extremal problem involving only that variable $\lambda$.

For any $r>0$, let us define the linear operator $A_{r}$ from $L^{2}\left(Q_{T}\right)$ into $L^{2}\left(Q_{T}\right)$ by

$$
A_{r} \lambda:=L \varphi, \quad \forall \lambda \in L^{2}\left(Q_{T}\right)
$$

where $\varphi \in \Phi$ is the unique solution to

$$
\begin{equation*}
a_{r}(\varphi, \bar{\varphi})=b(\bar{\varphi}, \lambda), \quad \forall \bar{\varphi} \in \Phi \tag{28}
\end{equation*}
$$

Notice that the assumption $r>0$ is necessary here in order to guarantee the well-posedness of (28). Precisely, for any $r>0$, the form $a_{r}$ defines a norm equivalent to the norm on $\Phi$ (see (19).

We have the following important lemma:
LEMMA 2.1 For any $r>0$, the operator $A_{r}$ is a strongly elliptic, symmetric isomorphism from $L^{2}\left(Q_{T}\right)$ into $L^{2}\left(Q_{T}\right)$.
Proof- From the definition of $a_{r}$, we easily get that $\left\|A_{r} \lambda\right\|_{L^{2}\left(Q_{T}\right)} \leq r^{-1}\|\lambda\|_{L^{2}\left(Q_{T}\right)}$ and the continuity of $A_{r}$. Next, consider any $\lambda^{\prime} \in L^{2}\left(Q_{T}\right)$ and denote by $\varphi^{\prime}$ the corresponding unique solution of 28) so that $A_{r} \lambda^{\prime}:=L \varphi^{\prime}$. Relation with $\bar{\varphi}=\varphi^{\prime}$ then implies that

$$
\begin{equation*}
\iint_{Q_{T}}\left(A_{r} \lambda^{\prime}\right) \lambda d x d t=a_{r}\left(\varphi, \varphi^{\prime}\right) \tag{29}
\end{equation*}
$$

and therefore the symmetry and positivity of $A_{r}$. The last relation with $\lambda^{\prime}=\lambda$ and the Carleman estimate 25 imply that $A_{r}$ is also positive definite.

Finally, let us check the strong ellipticity of $A_{r}$, equivalently that the bilinear functional $\left(\lambda, \lambda^{\prime}\right) \rightarrow \iint_{Q_{T}}\left(A_{r} \lambda\right) \lambda^{\prime} d x d t$ is $L^{2}\left(Q_{T}\right)$-elliptic. Thus we want to show that

$$
\begin{equation*}
\iint_{Q_{T}}\left(A_{r} \lambda\right) \lambda d x d t \geq C\|\lambda\|_{L^{2}\left(Q_{T}\right)}^{2}, \quad \forall \lambda \in L^{2}\left(Q_{T}\right) \tag{30}
\end{equation*}
$$

for some positive constant $C$. Suppose that 30 does not hold; there exists then a sequence $\left\{\lambda_{n}\right\}_{n \geq 0}$ of $L^{2}\left(Q_{T}\right)$ such that

$$
\left\|\lambda_{n}\right\|_{L^{2}\left(Q_{T}\right)}=1, \quad \forall n \geq 0, \quad \lim _{n \rightarrow \infty} \iint_{Q_{T}}\left(A_{r} \lambda_{n}\right) \lambda_{n} d x d t=0
$$

Let us denote by $\varphi_{n}$ the solution of (28) corresponding to $\lambda_{n}$. From 29), we then obtain that

$$
\begin{equation*}
\lim _{n \rightarrow \infty}\left\|L \varphi_{n}\right\|_{L^{2}\left(Q_{T}\right)}=0, \quad \lim _{n \rightarrow \infty}\left\|\varphi_{n, x}(1, \cdot)\right\|_{L^{2}(0, T)}=0 \tag{31}
\end{equation*}
$$

and thus $\lim _{n \rightarrow \infty} \iint_{Q_{T}} L \varphi \lambda_{n} d x d t=0$ for all $\varphi \in \Phi$ (and so the $L^{2}\left(Q_{T}\right)$-weak-convergence of $\lambda_{n}$ toward 0 ).

From 28 with $\varphi=\varphi_{n}$ and $\lambda_{n}$, we have

$$
\begin{equation*}
\iint_{Q_{T}}\left(r L \varphi_{n}-\lambda_{n}\right) L \bar{\varphi} d x d t+\int_{0}^{T} c(1) \varphi_{n, x}(1, \cdot) \bar{\varphi}_{x}(1, \cdot) d t=0, \quad \forall \bar{\varphi} \in \Phi \tag{32}
\end{equation*}
$$

We define the sequence $\left\{\bar{\varphi}_{n}\right\}_{n \geq 0}$ as follows:

$$
\begin{cases}L \bar{\varphi}_{n}=r L \varphi_{n}-\lambda_{n}, & \text { in } \quad Q_{T} \\ \bar{\varphi}_{n}(0, \cdot)=\bar{\varphi}_{n}(1, \cdot)=0, & \text { in }(0, T), \\ \bar{\varphi}_{n}(\cdot, 0)=\bar{\varphi}_{n, t}(\cdot, 0)=0, & \text { in } \quad(0,1)\end{cases}
$$

so that, for all $n, \bar{\varphi}_{n}$ is the solution of the wave equation with zero initial data and source term $r L \varphi_{n}-\lambda_{n}$ in $L^{2}\left(Q_{T}\right)$. Using again 27 , we get $\left\|\bar{\varphi}_{n, x}(1, \cdot)\right\| \leq C_{\Omega, T}\left\|r L \varphi_{n}-\lambda_{n}\right\|_{L^{2}\left(Q_{T}\right)}$, so that $\bar{\varphi}_{n} \in \Phi$. Then, using (32), we get

$$
\left\|r L \varphi_{n}-\lambda_{n}\right\|_{L^{2}\left(Q_{T}\right)} \leq C_{\Omega, T}\left\|\varphi_{n, x}(1, \cdot)\right\|_{L^{2}(0, T)}
$$

Then, from (31), we conclude that $\lim _{n \rightarrow+\infty}\left\|\lambda_{n}\right\|_{L^{2}\left(Q_{T}\right)}=0$ leading to a contradiction and to the strong ellipticity of the operator $A_{r}$.

The introduction of the operator $A_{r}$ is motivated by the following proposition :
Proposition 2.2 For any ría, let $\varphi_{0} \in \Phi$ be the unique solution of

$$
a_{r}\left(\varphi_{0}, \bar{\varphi}\right)=l(\bar{\varphi}), \quad \forall \bar{\varphi} \in \Phi
$$

and let $J^{\star \star}: L^{2}\left(Q_{T}\right) \rightarrow L^{2}\left(Q_{T}\right)$ be the functional defined by

$$
J^{\star \star}(\lambda)=\frac{1}{2} \iint_{Q_{T}}\left(A_{r} \lambda\right) \lambda d x d t-b\left(\varphi_{0}, \lambda\right)
$$

The following equality holds:

$$
\sup _{\lambda \in L^{2}\left(Q_{T}\right)} \inf _{\varphi \in \Phi} \mathcal{L}_{r}(\varphi, \lambda)=-\inf _{\lambda \in L^{2}\left(Q_{T}\right)} J^{\star \star}(\lambda) \quad+\mathcal{L}_{r}\left(\varphi_{0}, 0\right)
$$

Proof- For any $\lambda \in L^{2}\left(Q_{T}\right)$, let us denote by $\varphi_{\lambda} \in \Phi$ the minimizer of $\varphi \rightarrow \mathcal{L}_{r}(\varphi, \lambda) ; \varphi_{\lambda}$ satisfies the equation

$$
a_{r}\left(\varphi_{\lambda}, \bar{\varphi}\right)+b(\bar{\varphi}, \lambda)=l(\bar{\varphi}), \quad \forall \bar{\varphi} \in \Phi
$$

and can be decomposed as follows : $\varphi_{\lambda}=\psi_{\lambda}+\varphi_{0}$ where $\psi_{\lambda} \in \Phi$ solves

$$
a_{r}\left(\psi_{\lambda}, \bar{\varphi}\right)+b(\bar{\varphi}, \lambda)=0, \quad \forall \bar{\varphi} \in \Phi
$$

We then have

$$
\begin{aligned}
\inf _{\varphi \in \Phi} \mathcal{L}_{r}(\varphi, \lambda) & =\mathcal{L}_{r}\left(\varphi_{\lambda}, \lambda\right)=\mathcal{L}_{r}\left(\psi_{\lambda}+\varphi_{0}, \lambda\right) \\
& =\frac{1}{2} a_{r}\left(\psi_{\lambda}+\varphi_{0}, \psi_{\lambda}+\varphi_{0}\right)+b\left(\psi_{\lambda}+\varphi_{0}, \lambda\right)-l\left(\psi_{\lambda}+\varphi_{0}\right) \\
& :=X_{1}+X_{2}+X_{3}
\end{aligned}
$$

with

$$
\left\{\begin{array}{l}
X_{1}=\frac{1}{2} a_{r}\left(\psi_{\lambda}, \psi_{\lambda}\right)+b\left(\psi_{\lambda}, \lambda\right)+b\left(\varphi_{0}, \lambda\right) \\
X_{2}=a_{r}\left(\psi_{\lambda}, \varphi_{0}\right)-l\left(\psi_{\lambda}\right), \quad X_{3}=\frac{1}{2} a_{r}\left(\varphi_{0}, \varphi_{0}\right)-l\left(\varphi_{0}\right)
\end{array}\right.
$$

From the definition of $\varphi_{0}, X_{2}=0$ while $X_{3}=\mathcal{L}_{r}\left(\varphi_{0}, 0\right)$. Eventually, from the definition of $\psi_{\lambda}$,

$$
X_{1}=-\frac{1}{2} a_{r}\left(\psi_{\lambda}, \psi_{\lambda}\right)+b\left(\varphi_{0}, \lambda\right)=-\frac{1}{2} \iint_{Q_{T}}\left(A_{r} \lambda\right) \lambda d x d t+b\left(\varphi_{0}, \lambda\right)
$$

and the result follows.
From the ellipticity of the operator $A_{r}$, the minimization of the functional $J^{\star \star}$ over $L^{2}\left(Q_{T}\right)$ is well-posed. It is interesting to note that with this extremal problem involving only $\lambda$, we are coming to the primal variable, controlled solution of (1) (see Theorem 2.1. (iii)). Due to the constraint (4), the direct minimization of problem (5) with respect to the controlled state is usually avoided in practice. Here, any constraint equality is assigned to the variable $\lambda$.

From the symmetry and ellipticity of the operator $A_{r}$, the conjugate gradient algorithm is very appropriate to minimize $J^{\star \star}$, and consequently to solve the mixed formulation 200. The conjugate gradient algorithm reads as follows :
(i) Let $\lambda^{0} \in L^{2}\left(Q_{T}\right)$ be a given function.
(ii) Compute $\bar{\varphi}_{0} \in \Phi$ solution to

$$
a_{r}\left(\bar{\varphi}^{0}, \bar{\varphi}\right)+b\left(\bar{\varphi}, \lambda^{0}\right)=l(\bar{\varphi}), \quad \forall \bar{\varphi} \in \Phi
$$

and $g^{0}=L \varphi^{0}$ then set $w^{0}=g^{0}$.
(iii) For $n \geq 0$, assuming that $\lambda^{n}, g^{n}$ and $w^{n}$ are known, compute $\bar{\varphi}^{n} \in \Phi$ solution to

$$
a_{r}\left(\bar{\varphi}^{n}, \bar{\varphi}\right)=b\left(\bar{\varphi}, g^{n}\right), \quad \forall \bar{\varphi} \in \Phi
$$

and $\bar{g}^{n}=L \bar{\varphi}^{n}$ and then

$$
\rho_{n}=\left\|g^{n}\right\|_{L^{2}\left(Q_{T}\right)}^{2} / \iint_{Q_{T}} \bar{g}^{n} w^{n} d x d t
$$

Update $\lambda^{n}$ and $g^{n}$ by

$$
\lambda^{n+1}=\lambda^{n}-\rho_{n} w^{n}, \quad g^{n+1}=g^{n}-\rho^{n} \bar{g}^{n}
$$

If $\left\|g^{n+1}\right\|_{L^{2}\left(Q_{T}\right)} /\left\|g^{0}\right\|_{L^{2}\left(Q_{T}\right)} \leq \varepsilon$, take $\lambda=\lambda^{n+1}$. Else, compute

$$
\gamma_{n}=\left\|g^{n+1}\right\|_{L^{2}\left(Q_{T}\right)}^{2} /\left\|g^{n}\right\|_{L^{2}\left(Q_{T}\right)}^{2}
$$

and update $w^{n}$ via

$$
w^{n+1}=g^{n+1}+\gamma_{n} w^{n}
$$

Do $n=n+1$ and return to step (iii).
As mentioned in [18] where this approach is discussed in length for Stokes and Navier-Stokes system, this algorithm can be viewed as a sophisticated version of Uzawa type algorithm.

Concerning the speed of convergence of the conjugate gradient algorithm (i)-(iii), it follows, for instance, from [13] that

$$
\left\|\lambda^{n}-\lambda\right\|_{L^{2}\left(Q_{T}\right)} \leq 2 \sqrt{\nu\left(A_{r}\right)}\left(\frac{\sqrt{\nu\left(A_{r}\right)}-1}{\sqrt{\nu\left(A_{r}\right)}+1}\right)^{n}\left\|\lambda^{0}-\lambda\right\|_{L^{2}\left(Q_{T}\right)}, \quad \forall n \geq 1
$$

where $\lambda$ minimizes $J^{\star \star} . \nu\left(A_{r}\right)=\left\|A_{r}\right\|\left\|A_{r}^{-1}\right\|$ denotes the condition number of the operator $A_{r}$.
Eventually, once the above algorithm has converged we can compute $\varphi \in \Phi$ as solution of

$$
a_{r}(\varphi, \bar{\varphi})+b(\bar{\varphi}, \lambda)=l(\bar{\varphi}), \quad \forall \bar{\varphi} \in \Phi
$$

## 3 Mixed formulation for the distributed case

The mixed approach may be also used to address the inner situation, the main difference being the regularity of the initial data to be controlled. Let $\omega$ be a open and non empty subset of $(0,1)$ and $1_{\omega}$ its characteristic function. We set $q_{T}=\omega \times(0, T)$ and recall that $\Sigma_{T}=\{0,1\} \times(0, T)$. For any initial data $\left(y_{0}, y_{1}\right) \in H_{0}^{1}(0,1) \times L^{2}(0,1)$ and any $v \in L^{2}\left(q_{T}\right)$, the boundary value problem

$$
\begin{cases}L y=v 1_{\omega} & \text { in } Q_{T}  \tag{33}\\ y=0 & \text { on } \Sigma_{T} \\ \left(y(\cdot, 0), y_{t}(\cdot, 0)\right)=\left(y_{0}, y_{1}\right) & \text { in } \Omega\end{cases}
$$

is well-posed and the solution $y$ enjoys the regularity $y \in C^{0}\left([0, T] ; H_{0}^{1}(0,1)\right) \cap C^{1}\left([0, T] ; L^{2}(0,1)\right)$. Again, the controllability problem for 33 consists in finding a control function $v \in L^{2}\left(q_{T}\right)$ such that (4) holds.

The dual formulation associated to the control of minimal $L^{2}$-norm for 33 ) is

$$
\min _{\left(\varphi_{0}, \varphi_{1}\right) \in L^{2}(0,1) \times H^{-1}(0,1)} J^{\star}\left(\varphi_{0}, \varphi_{1}\right)=\frac{1}{2} \iint_{q_{T}}|\varphi|^{2} d x d t+<\varphi_{1}, y_{0}>_{H^{-1}(0,1), H_{0}^{1}(0,1)}-\int_{\Omega} \varphi_{0} y_{1} d x
$$

where the adjoint solution solves again the homogeneous adjoint equation (7). The dual formulation is well-posed as soon as $T$ is large enough: this is given by the inner version of the estimate (8) (see [27]) :
$\exists k_{T}>0 \quad$ such that $\left\|\varphi(\cdot, 0), \varphi_{t}(\cdot, 0)\right\|_{L^{2} \times H^{-1}} \leq k_{T}\|\varphi\|_{L^{2}\left(q_{T}\right)}, \quad \forall\left(\varphi_{0}, \varphi_{1}\right) \in L^{2}(0,1) \times H^{-1}(0,1)$
where $\varphi$ solves (7). As in the case of boundary control, since the solution of the adjoint system is completely determined by the initial data $\left(\varphi_{0}, \varphi_{1}\right)$, we $\operatorname{keep} \varphi$ as the minimization variable and consider the extremal problem

$$
\begin{equation*}
\min _{\varphi \in W} \hat{J}^{\star}(\varphi)=\frac{1}{2} \iint_{q_{T}}|\varphi|^{2} d x d t+<\varphi_{t}(\cdot, 0), y_{0}>_{H^{-1}(0,1), H_{0}^{1}(0,1)}-\int_{\Omega} \varphi(\cdot, 0) y_{1} d x \tag{34}
\end{equation*}
$$

where

$$
W=\left\{\varphi \in L^{2}\left(q_{T}\right), \varphi=0 \text { on } \Sigma_{T} \text { such that } L \varphi=0 \in L^{2}\left(0, T ; H^{-1}(0,1)\right)\right\}
$$

Following the lines of Section 2.1, $W$ is a Hilbert space endowed with the inner product

$$
(\varphi, \bar{\varphi})_{W}=\iint_{q_{T}} \varphi(x, t) \bar{\varphi}(x, t) d x d t+\eta \int_{0}^{T}<L \varphi, L \bar{\varphi}>_{H^{-1}(0,1), H^{-1}(0,1)} d t
$$

for any fixed $\eta>0$. We define

$$
\Phi=\left\{\varphi \in L^{2}\left(q_{T}\right), \varphi=0 \text { on } \Sigma_{T} \text { such that } L \varphi \in L^{2}\left(0, T ; H^{-1}(0,1)\right)\right\}
$$

and consider the following mixed formulation : find $(\varphi, \lambda) \in \Phi \times L^{2}\left(0, T ; H_{0}^{1}(0,1)\right)$ solution of

$$
\left\{\begin{align*}
a(\varphi, \bar{\varphi})+b(\bar{\varphi}, \lambda) & =l(\bar{\varphi}), & & \forall \bar{\varphi} \in \Phi  \tag{35}\\
b(\varphi, \bar{\lambda}) & =0, & & \forall \bar{\lambda} \in L^{2}\left(0, T ; H_{0}^{1}(0,1)\right),
\end{align*}\right.
$$

where

$$
\begin{aligned}
& a: \Phi \times \Phi \rightarrow \mathbb{R}, \quad a(\varphi, \bar{\varphi})=\iint_{q_{T}} \varphi(x, t) \bar{\varphi}(x, t) d x d t \\
& b: \Phi \times L^{2}\left(0, T ; H_{0}^{1}(0,1)\right) \rightarrow \mathbb{R}, \quad b(\varphi, \lambda)=\int_{0}^{T}<L \varphi, \lambda>_{H^{-1}, H_{0}^{1}} d t \\
& l: \Phi \rightarrow \mathbb{R}, \quad l(\varphi)=-<\varphi_{t}(\cdot, 0), y_{0}>_{H^{-1}(0,1), H_{0}^{1}(0,1)}+\int_{0}^{1} \varphi(\cdot, 0) y_{1} d x .
\end{aligned}
$$

In the remaining part of this section we assume that $\omega, T$ and the wave operator $L$ are such that the following holds : there exists a constant $C_{0}$ (depending on $\omega, T$ and the wave operator $L$ ) such that

$$
\begin{equation*}
\left\|\varphi(\cdot, 0), \varphi_{t}(\cdot, 0)\right\|_{L^{2} \times H^{-1}}^{2} \leq C_{0}\left(\|L \varphi\|_{L^{2}\left(0, T ; H^{-1}(0,1)\right)}^{2}+\|\varphi\|_{L^{2}\left(q_{T}\right)}^{2}\right), \quad \forall \varphi \in \Phi \tag{36}
\end{equation*}
$$

This estimate can be proved using Carleman estimates (see [25, 34) or by the means of multipliers method (see [23]). We refer to [7] for a proof in the more general case where the subset $\omega$ depends on the time variable. Inequality $(36)$ is the main ingredient to prove an equivalent result to Theorem 2.1 in the case of distributed control.

Theorem 3.1 (i) The mixed formulation (35) is well-posed.
(ii) The unique solution $(\varphi, \lambda) \in \Phi \times L^{2}\left(0, T ; H^{-1}(0,1)\right)$ is the unique saddle-point of the Lagrangian $\mathcal{L}: \Phi \times L^{2}\left(0, T ; H^{-1}(0,1)\right) \rightarrow \mathbb{R}$ defined by $\mathcal{L}(\varphi, \lambda)=\frac{1}{2} a(\varphi, \varphi)+b(\varphi, \lambda)-l(\varphi)$.
(iii) The optimal function $\varphi$ is the minimizer of $\hat{J}^{\star}$, defined by (34), over $\Phi$ while the optimal function $\lambda \in L^{2}\left(Q_{T}\right)$ is the state of the controlled wave equation (1) in the weak sense.

Since we assume that (36) holds, the proof of Theorem (3.1) is similar to the one of Theorem 2.1, and all the methodology described in Section 2 applies to approximate the distributed control of minimal $L^{2}\left(q_{T}\right)$-norm. We omit the details and refer to [7] for a more general situation. Numerical results for the approximation of distributed control of minimal $L^{2}$-norm are discussed at the end of Section 4 .

Remark 2 The result of this section remains true if we define the space $W$ such that $L \varphi$ belongs to $L^{2}\left(Q_{T}\right)$. This allows to avoid scalar product over $H^{-1}$. The estimate (36) still holds and the multiplier $\lambda$ is now only in $L^{2}\left(Q_{T}\right)$ and is a controlled solution of (33) in the sense of the transposition. As for the boundary situation, we may also work with $\left(\varphi(\cdot, 0) ; \varphi_{t}(\cdot, 0)\right)$ in $H_{0}^{1}(0,1) \times$ $L^{2}(0,1)$ leading naturally to $L \varphi=0$ as an $L^{2}\left(Q_{T}\right)$ function: however, the controls we then get are only in $H^{-1}\left(q_{T}\right)$ (see [27, Chapter 7, Section 2]).

## 4 Numerical approximation and experiments

### 4.1 Discretization

We now turn to the discretization of the mixed formulation assuming $r>0$.
Let then $\Phi_{h}$ and $M_{h}$ be two finite dimensional spaces parametrized by the variable $h$ such that

$$
\Phi_{h} \subset \Phi, \quad M_{h} \subset L^{2}\left(Q_{T}\right), \quad \forall h>0
$$

Then, we can introduce the following approximated problems : find $\left(\varphi_{h}, \lambda_{h}\right) \in \Phi_{h} \times M_{h}$ solution of

$$
\left\{\begin{align*}
a_{r}\left(\varphi_{h}, \bar{\varphi}_{h}\right)+b\left(\bar{\varphi}_{h}, \lambda_{h}\right) & =l\left(\bar{\varphi}_{h}\right), & & \forall \bar{\varphi}_{h} \in \Phi_{h}  \tag{37}\\
b\left(\varphi_{h}, \bar{\lambda}_{h}\right) & =0, & & \forall \bar{\lambda}_{h} \in M_{h}
\end{align*}\right.
$$

The well-posedness of this mixed formulation is again a consequence of two properties : the coercivity of the bilinear form $a_{r}$ on the subset $\mathcal{N}_{h}(b)=\left\{\varphi_{h} \in \Phi_{h} ; b\left(\varphi_{h}, \lambda_{h}\right)=0 \quad \forall \lambda_{h} \in M_{h}\right\}$. Actually, from the relation

$$
a_{r}(\varphi, \varphi) \geq \frac{r}{\eta}\|\varphi\|_{\Phi}^{2}, \quad \forall \varphi \in \Phi
$$

the form $a_{r}$ is coercive on the full space $\Phi$, and so a fortiori on $\mathcal{N}_{h}(b) \subset \Phi_{h} \subset \Phi$. The second property is a discrete inf-sup condition : there exists $\delta_{h}>0$ such that

$$
\begin{equation*}
\inf _{\lambda_{h} \in M_{h}} \sup _{\varphi_{h} \in \Phi_{h}} \frac{b\left(\varphi_{h}, \lambda_{h}\right)}{\left\|\varphi_{h}\right\|_{\Phi_{h}}\left\|\lambda_{h}\right\|_{M_{h}}} \geq \delta_{h} \tag{38}
\end{equation*}
$$

For any fixed $h$, the spaces $M_{h}$ and $\Phi_{h}$ are of finite dimension so that the infimum and supremum in (38) are reached: moreover, from the property of the bilinear form $a_{r}$, it is standard to prove that $\delta_{h}$ is strictly positive (see Section 4.2). Consequently, for any fixed $h>0$, there exists a unique couple $\left(\varphi_{h}, \lambda_{h}\right)$ solution of 37 ). On the other hand, the property $\inf _{h} \delta_{h}>0$ is in general difficult to prove and depends strongly on the choice made for the approximated spaces $M_{h}$ and $\Phi_{h}$. We shall analyze numerically this property in Section 4.2 .

As in [11], the finite dimensional and conformal space $\Phi_{h}$ must be chosen such that $L \varphi_{h}$ belongs to $L^{2}\left(Q_{T}\right)$ for any $\varphi_{h} \in \Phi_{h}$. This is guaranteed as soon as $\varphi_{h}$ possesses second-order derivatives in
$L_{l o c}^{2}\left(Q_{T}\right)$. Therefore, a conformal approximation based on standard triangulation of $Q_{T}$ requires spaces of functions continuously differentiable with respect to both variables $x$ and $t$.

We introduce a triangulation $\mathcal{T}_{h}$ such that $\overline{Q_{T}}=\cup_{K \in \mathcal{T}_{h}} K$ and we assume that $\left\{\mathcal{I}_{h}\right\}_{h>0}$ is a regular family. Then, we introduce the space $\Phi_{h}$ as follows :

$$
\Phi_{h}=\left\{\varphi_{h} \in C^{1}\left(\overline{Q_{T}}\right):\left.\varphi_{h}\right|_{K} \in \mathbb{P}(K) \quad \forall K \in \mathcal{T}_{h}, \varphi_{h}=0 \text { on } \Sigma_{T}\right\}
$$

where $\mathbb{P}(K)$ denotes an appropriate space of polynomial functions in $x$ and $t$. In this work, we consider the following two choices for $\mathbb{P}(K)$ :
(i) The Bogner-Fox-Schmit (BFS for short) $C^{1}$ element defined for rectangles. It involves 16 degrees of freedom, namely the values of $\varphi_{h}, \varphi_{h, x}, \varphi_{h, t}, \varphi_{h, x t}$ on the four vertices of each rectangle $K$. Therefore $\mathbb{P}(K)=\mathbb{P}_{3, x} \otimes \mathbb{P}_{3, t}$ where $\mathbb{P}_{r, \xi}$ is by definition the space of polynomial functions of order $r$ in the variable $\xi$. We refer to [10] page 76;
(ii) The reduced Hsieh-Clough-Tocher (HCT for short) $C^{1}$ element defined for triangles. This is a so-called composite finite element and involves 9 degrees of freedom, namely the values of $\varphi_{h}, \varphi_{h, x}, \varphi_{h, t}$ on the three vertices of each triangle $K$. We refer to [10] page 356 and to [3, 29] where the implementation is discussed.

We also define the finite dimensional space

$$
M_{h}=\left\{\lambda_{h} \in C^{0}\left(\overline{Q_{T}}\right):\left.\lambda_{h}\right|_{K} \in \mathbb{Q}(K) \quad \forall K \in \mathcal{T}_{h}\right\},
$$

where $\mathbb{Q}(K)$ denotes the space of affine functions both in $x$ and $t$ on the element $K$. For any $h>0$, we have $\Phi_{h} \subset \Phi$ and $M_{h} \subset L^{2}\left(Q_{T}\right)$.

Let $n_{h}=\operatorname{dim} \Phi_{h}, m_{h}=\operatorname{dim} M_{h}$ and let the real matrices $A_{r, h} \in \mathbb{R}^{n_{h}, n_{h}}, B_{h} \in \mathbb{R}^{m_{h}, n_{h}}$, $J_{h} \in \mathbb{R}^{m_{h}, m_{h}}$ and $L_{h} \in \mathbb{R}^{n_{h}}$ be defined by

$$
\left\{\begin{array}{l}
a_{r}\left(\varphi_{h}, \overline{\varphi_{h}}\right)=<A_{r, h}\left\{\varphi_{h}\right\},\left\{\overline{\varphi_{h}}\right\}>_{\mathbb{R}^{n_{h}}, \mathbb{R}^{n_{h}}}, \quad \forall \varphi_{h}, \overline{\varphi_{h}} \in \Phi_{h}, \\
b\left(\varphi_{h}, \lambda_{h}\right)=<B_{h}\left\{\varphi_{h}\right\},\left\{\lambda_{h}\right\}>_{\mathbb{R}^{m_{h}}, \mathbb{R}^{m_{h}}, \quad \forall \varphi_{h} \in \Phi_{h}, \forall \lambda_{h} \in M_{h}}\left\{\begin{array}{l}
\iint_{Q_{T}} \lambda_{h} \overline{\lambda_{h}} d x d t=<J_{h}\left\{\lambda_{h}\right\},\left\{\overline{\lambda_{h}}\right\}>_{\mathbb{R}^{m_{h}}, \mathbb{R}^{m_{h}}}, \quad \forall \lambda_{h}, \overline{\lambda_{h}} \in M_{h}, \\
l\left(\varphi_{h}\right)=<L_{h},\left\{\varphi_{h}\right\}>, \quad \forall \varphi_{h} \in \Phi_{h}
\end{array} .\right.
\end{array}\right.
$$

where $\left\{\varphi_{h}\right\} \in \mathbb{R}^{n_{h}, 1}$ denotes the vector associated to $\varphi_{h}$ and $<\cdot, \cdot>_{\mathbb{R}^{n_{h}}, \mathbb{R}^{n_{h}}}$ the usual scalar product over $\mathbb{R}^{n_{h}}$. With these notations, the problem (37) reads as follows : find $\left\{\varphi_{h}\right\} \in \mathbb{R}^{n_{h}}$ and $\left\{\lambda_{h}\right\} \in \mathbb{R}^{m_{h}}$ such that

$$
\left(\begin{array}{cc}
A_{r, h} & B_{h}^{T}  \tag{39}\\
B_{h} & 0
\end{array}\right)_{\mathbb{R}^{n_{h}+m_{h}, n_{h}+m_{h}}}\binom{\left\{\varphi_{h}\right\}}{\left\{\lambda_{h}\right\}}_{\mathbb{R}^{n_{h}+m_{h}}}=\binom{L_{h}}{0}_{\mathbb{R}^{n_{h}+m_{h}}}
$$

The matrix $A_{r, h}$ as well as the mass matrix $J_{h}$ are symmetric and positive definite for any $h>0$ and any $r>0$. On the other hand, the matrix of order $m_{h}+n_{h}$ in 39) is symmetric but not positive definite. We use exact integration methods developed in [14] for the evaluation of the coefficients of the matrices. The system (39) is solved using the direct LU decomposition method.

Let us also mention that for $r=0$, althought the formulation 20 is well-posed, numerically, the corresponding matrix $A_{0, h}$ is not invertible. In the sequel, we shall consider strictly positive values for $r$.

Once an approximation $\varphi_{h}$ is obtained, the relation (17) leads to an approximation $v_{h}$ of the control $v$ : precisely, we define

$$
\begin{equation*}
v_{h}=c(1) \pi_{\Delta t}\left(\varphi_{h, x}(1, \cdot)\right) \quad \text { in } \quad(0, T) \tag{40}
\end{equation*}
$$

where $\pi_{\Delta t}$ denotes the projection operator on the space of piecewise affine time function: $v_{h}$ is piecewise linear and coincides at each node (of the mesh $\mathcal{T}_{h}$ ) that belongs to the boundary $\{1\} \times(0, T)$, with $c(1) \varphi_{h, x}(1, \cdot)$. Note that in view of the definition of the space $\Phi_{h}$, the derivative with respect to $x$ of $\varphi_{h}$ is a degree of freedom of $\left\{\varphi_{h}\right\}$ : hence, the computation of $v_{h}$ does not require any additional calculus. The corresponding controlled state $y_{h}$ may be obtained by solving (1) with standard forward approximation (we refer to [11], Section 4 where this is detailed). Here, since the controlled state is directly given by the multiplier $\lambda$, we simply use $\lambda_{h}$ as an approximation of $y$ and we do not report here the computation of $y_{h}$.

Let us now comment on the meshes we use in the next section.
For the Bogner-Fox-Schmidt (BFS) finite element, we use uniform rectangular meshes. Each element is a rectangle of lengths $\Delta x$ and $\Delta t ; \Delta x>0$ and $\Delta t>0$ denote as usual the discretization parameters in space and time respectively. In the numerical experiments, we shall consider five levels of meshes, that is we consider $(\Delta x, \Delta t)=(1 / N, 1 / N)$ for $N=10,20,40,80$ and $N=160$.

For the Hsieh-Clough-Tocher (HCT), we use two types of meshes :

- Uniform triangular meshes obtained from the previous one by dividing each rectangle into two: thus, all the elements are rectangular triangles of the same shape and size, determined by $\Delta x$ and $\Delta t$.
- Non uniform but regular triangular meshes obtained by Delaunay triangulation. Each triangle of the mesh touching the boundaries $(0,1) \times\{0, T\}$ has the side on the boundary of length $\Delta x$; similarly, each triangle touching the boundaries $\{0,1\} \times(0, T)$ has the side on that boundary of length $\Delta t$.
Again, for the HCT element, we shall consider five levels of meshes: $(\Delta x, \Delta t)=(1 / N, T /(2 N))$ for $N=10,20,40,80$ and $N=160$. As an example, Figure 1 displays uniform rectangular, uniform and non-uniform triangular meshes of $Q_{T}$ for $N=10$ and $T=2$.

Figure 1: Meshes for $N=10$. From left to right : a rectangular mesh used for BFS, a triangular uniform mesh and a triangular non-uniform mesh used for HCT.

We note

$$
h:=\max \left\{\operatorname{diam}(K), K \in \mathcal{T}_{h}\right\}
$$

where $\operatorname{diam}(K)$ denotes the diameter of $K$; the parameter $h$ decreases as the parameter $N$, defining the fineness of the mesh, increases. Table 1 reports for $T=2$ the corresponding number of elements and nodes with respect to $N$.

| $N$ | 10 | 20 | 40 | 80 | 160 |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\operatorname{card}\left(\mathcal{T}_{h}\right)-$ BFS | 200 | 800 | 3200 | 12800 | 51200 |
| $\operatorname{card}\left(\mathcal{T}_{h}\right)-$ HCT uniform | 400 | 1600 | 6400 | 25600 | 102400 |
| $\operatorname{card}\left(\mathcal{T}_{h}\right)-$ HCT non uniform | 568 | 2272 | 9088 | 36452 | 145408 |

| $h$ HCT non uniform | $9.02 \times 10^{-2}$ | $4.51 \times 10^{-2}$ | $2.55 \times 10^{-2}$ | $1.13 \times 10^{-2}$ | $5.6 \times 10^{-3}$ |

Table 1: Number of elements (rectangle for BFS and triangle for HCT), number of nodes and value of $h$ for each type of meshes w.r.t. to the integer $N-T=2$.

### 4.2 The discrete inf-sup test

Before to give and discuss some numerical experiments, we first test numerically the discrete infsup condition (38). Taking $\eta=r>0$ so that $a_{r}(\varphi, \bar{\varphi})=(\varphi, \bar{\varphi})_{\Phi}$ exactly for all $\varphi, \bar{\varphi} \in \Phi$, it is readily seen (see for instance [9]) that the discrete inf-sup constant satisfies

$$
\begin{equation*}
\delta_{h}=\inf \left\{\sqrt{\delta}: B_{h} A_{r, h}^{-1} B_{h}^{T}\left\{\lambda_{h}\right\}=\delta J_{h}\left\{\lambda_{h}\right\}, \quad \forall\left\{\lambda_{h}\right\} \in \mathbb{R}^{m_{h}} \backslash\{0\}\right\} \tag{41}
\end{equation*}
$$

The matrix $B_{h} A_{r, h}^{-1} B_{h}^{T}$ enjoys the same properties than the matrix $A_{r, h}$ : it is symmetric and positive definite so that the scalar $\delta_{h}$ defined in term of the (generalized) eigenvalue problem 41) is strictly positive. This eigenvalue problem is solved using the power iteration algorithm (assuming that the lowest eigenvalue is simple): for any $\left\{v_{h}^{0}\right\} \in \mathbb{R}^{n_{h}}$ such that $\left\|\left\{v_{h}^{0}\right\}\right\|_{2}=1$, compute for any $n \geq 0,\left\{\varphi_{h}^{n}\right\} \in \mathbb{R}^{n_{h}},\left\{\lambda_{h}^{n}\right\} \in \mathbb{R}^{m_{h}}$ and $\left\{v_{h}^{n+1}\right\} \in \mathbb{R}^{m_{h}}$ iteratively as follows :

$$
\left\{\begin{array}{l}
A_{r, h}\left\{\varphi_{h}^{n}\right\}+B_{h}^{T}\left\{\lambda_{h}^{n}\right\}=0 \\
B_{h}\left\{\varphi_{h}^{n}\right\}=-J_{h}\left\{v_{h}^{n}\right\}
\end{array} \quad, \quad\left\{v_{h}^{n+1}\right\}=\frac{\left\{\lambda_{h}^{n}\right\}}{\left\|\left\{\lambda_{h}^{n}\right\}\right\|_{2}}\right.
$$

The scalar $\delta_{h}$ defined by 41 is then given by : $\delta_{h}=\lim _{n \rightarrow \infty}\left(\left\|\left\{\lambda_{h}^{n}\right\}\right\|_{2}\right)^{-1 / 2}$.
We now give some numerical values of $\delta_{h}$ with respect to $N$ (equivalently with respect to $h$ ) for the two $C^{1}$ finite elements introduced in Section 4.1. We take here for simplicity $c:=1$ and $d:=0$ so that $L \varphi:=\varphi_{t t}-\varphi_{x x}$. Values of $c$ and $d$ do not affect qualitatively the results.

Table 2 is concerned with the BFS element and $T=2$. Table 3 is concerned with the HCT element for uniform meshes. Table 4 is concerned with the HCT element for non uniform meshes.

As expected, we check that $\delta_{h}$ decreases as $h \rightarrow 0$ and increases as $r \rightarrow 0$. More importantly, we observe that for any $r$, the value of $\delta_{h}$ does not seem to be bounded by below with respect to the discretization parameter: for low values of $r$, the decrease of $\delta_{h}$ as $h \rightarrow 0$ seems however very slow (see first row of Table 2 and Figure 2). We recall that the scalars $r, \eta$ are arbitrary as long as they are strictly positive, so that the form $a_{r}$ defines a scalar product over $\Phi$. In the first two cases where the meshes are uniform (that is $\Delta t=\Delta x$ ), it is worth to note that we obtain the same behavior when $\Delta x \neq \Delta t$.

We may conclude that the two finite elements considered here do not "pass" the discrete inf-sup test. As we shall see in the next section, this interesting fact does not prevent the convergence of the sequence $\varphi_{h}$ and $\lambda_{h}$, at least for the cases we have considered. Interestingly, we also observe that the discrete inf-sup constant $\delta_{h}$ remains bounded with respect to $h$ when the parameter $r$ depends appropriately on $h$ (last row of Tables 2, 3, 4,

| $h$ | $1.41 \times 10^{-1}$ | $7.01 \times 10^{-2}$ | $3.53 \times 10^{-2}$ | $1.76 \times 10^{-2}$ | $8.83 \times 10^{-3}$ |

### 4.3 Numerical experiments: the boundary case

We first address the boundary case for three initial data with various regularity and for which we know explicitly the control $v$ of minimal $L^{2}$-norm. This allows to evaluate precisely the error $\left\|v-v_{h}\right\|_{L^{2}(0, T)}$ with respect to $h$ and confirm the relevance of the method. For these three examples, we take $c:=1$ and $d:=0$.

For any $m \in \mathbb{N}$, let us first consider the initial condition

$$
(\mathbf{E X 1}) \quad y_{0}(x)=\sin (m \pi x), \quad y_{1}(x)=0, \quad T=2
$$

for which the control of minimal $L^{2}$-norm is given by $v(t)=\frac{1}{2}(-1)^{m+1} \sin (m \pi t)$ on $[0, T]$ while the adjoint state $\varphi \in \Phi$, minimizer of the conjugate functional $\hat{J}^{\star}$ (see 18 ) has the expression $\varphi(x, t)=-\frac{1}{2 m \pi} \sin (m \pi t) \sin (m \pi x)$ in $Q_{T}$. We have $\|v\|_{L^{2}(0, T)}=1 / 2$.

We take $m=3$. We first give some numerical values obtained with the BFS element. Tables 5 and 6 collect some numerical values for $r=10^{-2}$ and $r=1$ respectively. Values corresponding to $r=10^{-4}, h^{2}$ and $r=10^{2}$ are reported in the Appendix, Table 21, 22, 23,

In the Tables, $\kappa$ denotes the condition number associated to 39 , independent of the initial data $\left(y_{0}, y_{1}\right){ }^{1}$.

The convergence of $\left\|\varphi-\varphi_{h}\right\|_{L^{2}\left(Q_{T}\right)},\left\|v-v_{h}\right\|_{L^{2}(0, T)}$ and $\left\|L \varphi_{h}\right\|_{L^{2}\left(Q_{T}\right)}$ toward zero as $h \rightarrow 0$ is observed. We observe that, as soon as $h$ is small enough, the value of the positive parameter $r>0$ has a reduced impact on the results.

We observe that a low value of $r$, for instance $r=10^{-4}$, (providing a "better" inf-sup constant $\delta_{h}$ ) leads to a faster convergence of the Lagrangian variable $\lambda_{h}$ than the value $r=1$. This is in agreement with the classical estimates for mixed finite element approximation. Note that the phenomenon is however restricted here. On the other hand, a larger value of $r$ allows a faster convergence of the dual variable $\varphi_{h}$, since the constraint is better represented (observe the locking phenomenon for $r=10^{-2}$ when $h$ is large, Table 23). The case $r=h^{2}$ (Table 22) offers an interesting compromise, although quite large values for $\left\|L \varphi_{h}\right\|_{L^{2}\left(Q_{T}\right)}$. Moreover, this case provides the lowest values for $\kappa$. Finally, in every case, the condition number behaves polynomially with respect to $h$.

[^1]We compute

$$
\begin{aligned}
& r=1: \quad\left\|\varphi-\varphi_{h}\right\|_{L^{2}\left(Q_{T}\right)} \approx O\left(h^{3.9}\right), \quad\left\|v-v_{h}\right\|_{L^{2}(0, T)} \approx O\left(h^{3.5}\right), \quad\left\|L \varphi_{h}\right\|_{L^{2}\left(Q_{T}\right)} \approx O\left(h^{1.96}\right) \\
& r=10^{-2}: \quad\left\|\varphi-\varphi_{h}\right\|_{L^{2}\left(Q_{T}\right)} \approx O\left(h^{3}\right), \quad\left\|v-v_{h}\right\|_{L^{2}(0, T)} \approx O\left(h^{2 .}\right), \quad\left\|L \varphi_{h}\right\|_{L^{2}\left(Q_{T}\right)} \approx O\left(h^{1.92}\right)
\end{aligned}
$$

Table 6: Example EX1 - BFS element $-r=1$.
Tables 7 and 8 report the result obtained for the HCT element on uniform meshes for $r=1$ and $r=10^{-2}$ respectively. For this element, we observe that the value of $r$ has a deeper impact on the quality of the result. The convergence observed for $r=10$ w.r.t. $h$ is very slow (see Table 24 in the appendix). A better convergence is observed for lower values ( $r=1,10^{-2}$ and lower). We compute that:

$$
\begin{aligned}
& r=1: \quad\left\|\varphi-\varphi_{h}\right\|_{L^{2}\left(Q_{T}\right)} \approx O\left(h^{1.13}\right), \quad\left\|v-v_{h}\right\|_{L^{2}(0, T)} \approx O\left(h^{1.15}\right) \\
& r=10^{-2}: \quad\left\|\varphi-\varphi_{h}\right\|_{L^{2}\left(Q_{T}\right)} \approx O\left(h^{2.21}\right), \quad\left\|v-v_{h}\right\|_{L^{2}(0, T)} \approx O\left(h^{2.08}\right)
\end{aligned}
$$

The rates of convergence for the HCT element-uniform mesh are significantly reduced with respect to the rates obtained for the BFS element: as a possible explanation, we emphasize that the BFS element is slightly richer since he contains in addition the cross derivative $\varphi_{h, x t}$ as degree of freedom. We also observe that the influence of the parameter $r$ is even more important for non uniform mesh when the HCT element is used (see Tables 27, 28), so that this element seems more sensitive to the lack of uniform inf-sup property discussed in Section 4.2. In this respect, when $r$ behaves like $h^{2}$, we observe in both cases a very good convergence of the variable $\varphi_{h}$ and $\lambda_{h}$ together with a significant reduction of the condition number $\kappa$ (see Table 25). Again, this condition number increases polynomially as $h$ goes to 0 . We recall that the condition number of the discrete HUM operator blows up exponentially w.r.t. $h$ when a non uniformly controllable approximation is used (see [30]).

The second initial data corresponds to a continuous but not $C^{1}(0,1)$ initial position :
(EX2)

$$
y_{0}(x)=16 x^{3} 1_{(0,1 / 2)}(x)+16(1-x)^{3} 1_{(1 / 2,1)}(x), \quad y_{1}(x)=0, \quad T=2
$$

for which the control of minimal $L^{2}$-norm is given by

$$
v(t)=8 t^{3} 1_{(0,1 / 2)}(t)+8(1-t)^{3} 1_{(1 / 2,3 / 2)}(t)-8(2-t)^{3} 1_{(3 / 2,2)}(t), \quad t \in(0, T)
$$

Table 8: Example EX1 - HCT element - Uniform mesh - $r=10^{-2}$.
leading to $\|v\|_{L^{2}(0, T)}=\sqrt{14} / 7 \approx 0.53452$.
Tables 9 and 10 collect some values for $r=1$ and $r=10^{-2}$ respectively when the BFS finite element is used. Again, the influence of the value of $r$ is weak. For this set of data, less regular than the previous one, we observe a lower rate of convergence with respect to $h$ :

$$
\begin{aligned}
& r=1: \quad\left\|v-v_{h}\right\|_{L^{2}(0, T)} \approx e^{-0.71} h^{0.93}, \quad\left\|L \varphi_{h}\right\|_{L^{2}\left(Q_{T}\right)} \approx e^{-0.54} h^{0.96} \\
& r=10^{-2}: \quad\left\|v-v_{h}\right\|_{L^{2}(0, T)} \approx e^{-1.28} h^{0.78}, \quad\left\|L \varphi_{h}\right\|_{L^{2}\left(Q_{T}\right)} \approx e^{3.66} h^{1.56}
\end{aligned}
$$

| $h$ | $1.41 \times 10^{-1}$ | $7.01 \times 10^{-2}$ | $3.53 \times 10^{-2}$ | $1.76 \times 10^{-2}$ | $8.83 \times 10^{-3}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\left\\|v_{h}\right\\|_{L^{2}(0, T)}$ | 0.5291 | 0.5325 | 0.5339 | 0.5343 | 0.5344 |
| $\left\\|v-v_{h}\right\\|_{L^{2}(0, T)}$ | $7.62 \times 10^{-2}$ | $4.19 \times 10^{-2}$ | $2.20 \times 10^{-2}$ | $1.13 \times 10^{-2}$ | $5.76 \times 10^{-3}$ |
| $\left\\|\lambda_{h}\right\\|_{L^{2}\left(Q_{T}\right)}$ | 0.541 | 0.536 | 0.5349 | 0.5346 | 0.5345 |

Table 9: Example EX2 - BFS element $-r=1$.
Tables 11 and 12 correspond to $r=1$ and $r=10^{-2}$ respectively when the HCT element with non uniform meshes is used. We obtain again a slightly lower rate of convergence :

$$
\begin{aligned}
& r=1: \quad\left\|v-v_{h}\right\|_{L^{2}(0, T)} \approx e^{0.01} h^{0.71}, \quad\left\|L \varphi_{h}\right\|_{L^{2}\left(Q_{T}\right)} \approx e^{-0.32} h^{0.56} \\
& r=10^{-2}: \quad\left\|v-v_{h}\right\|_{L^{2}(0, T)} \approx e^{-1.06} h^{0.84}, \quad\left\|L \varphi_{h}\right\|_{L^{2}\left(Q_{T}\right)} \approx e^{2.97} h^{1.09}
\end{aligned}
$$

The third example is much stiffer in the sense that the initial position belongs to $L^{2}(0,1)$ but is discontinuous:
(EX3) $\quad y_{0}(x)=4 x 1_{(0,1 / 2)}(x), \quad y_{1}(x)=0, \quad T=2.4$.
The corresponding control of minimal $L^{2}$-norm, discontinuous, is given by $v(t)=2(1-t) 1_{(1 / 2,3 / 2)}(t)$, $t \in(0, T)$ so that $\|v\|_{L^{2}(0, T)}=1 / \sqrt{3} \approx 0.5773$. When the classical dual method (that is, the minimization of a discrete conjugate functional with respect to the initial data of the adjoint solution) is employed, adapted schemes are needed to obtain convergent results (we refer to [30] and the references therein).

Table 11: Example EX2 - HCT element - Non uniform mesh - $r=1$.

Table 13 collects some values for $r=1$ when the BFS finite element is used (the case $r=10^{-2}$ gives very closed results and is reported in Table 31, see the appendix). We observe the following rate of convergence with respect to $h$ :

$$
\begin{aligned}
& r=1: \quad\left\|v-v_{h}\right\|_{L^{2}(0, T)} \approx e^{-0.37} h^{0.45}, \quad\left\|L \varphi_{h}\right\|_{L^{2}\left(Q_{T}\right)} \approx e^{-1.57} h^{0.37} \\
& r=10^{-2}: \quad\left\|v-v_{h}\right\|_{L^{2}(0, T)} \approx e^{-0.09} h^{0.52}, \quad\left\|L \varphi_{h}\right\|_{L^{2}\left(Q_{T}\right)} \approx e^{2.46} h^{0.72}
\end{aligned}
$$

It is interesting to note, as in the previous examples, that a rather good approximation $v_{h}$ of the control is obtained with a quite large value of the $L^{2}$-norm of $L \varphi_{h}$. Table 13 also indicates that the $H^{-1}\left(Q_{T}\right)$-norm of $L \varphi_{h}$ is almost zero. This is due to the fact that the variable $\varphi_{h} \in \Phi_{h}$ satisfies $b\left(\varphi_{h}, \lambda_{h}\right)=0$ for all $\lambda_{h} \in M_{h}$, that $M_{h}$ is also a conformal approximation of $H^{1}(0,1)$ and that $\left\|L \varphi_{h}\right\|_{H^{-1}(0,1)}=\sup _{l \in H^{1}(0,1),\|l\|_{H^{1}}=1}\left|b\left(\varphi_{h}, l\right)\right|$. For any $h$ and any $r$, the adjoint variable $\varphi_{h}$ satisfies the wave equation in a weak sense. This phenomenon is highlighted in Table 14 small values of $r$ (for instance $r=10^{-6}, h$ being fixed) leads to large values of $\left\|L \varphi_{h}\right\|_{L^{2}(0,1)}$ but to good approximations $\lambda_{h}$ and $v_{h}$ of the controlled solution and of the control respectively.

Tables 15 and 16 provide the results for $r=1$ obtained with the reduced HCT for uniform and non-uniform meshes respectively :
$r=1$ - HCT uniform mesh : $\quad\left\|v-v_{h}\right\|_{L^{2}(0, T)} \approx e^{-0.86} h^{0.22}, \quad\left\|L \varphi_{h}\right\|_{L^{2}\left(Q_{T}\right)} \approx e^{-0.91} h^{0.32}$,
$r=1-$ HCT non uniform mesh $: \quad\left\|v-v_{h}\right\|_{L^{2}(0, T)} \approx e^{-1.03} h^{0.25}, \quad\left\|L \varphi_{h}\right\|_{L^{2}\left(Q_{T}\right)} \approx e^{-0.55} h^{0.46}$.
Figure 3 depicts the evolution of the error $\left\|v-v_{h}\right\|_{L^{2}(0, T)}$ w.r.t. $h$ for the BFS and HCT element. Closed results are observed for $r=10^{-2}$, reported Tables 32 and 33 in the appendix.

Figure 4 depicts the corresponding approximation $v_{h}$ of the HUM control on $(0, T)$ and confirm the remarkable approximation we get in this stiff case. Figures 5 and 6 depict the variable $\varphi_{h} \subset \Phi_{h}$ and the multiplier $\lambda_{h} \subset M_{h}$ in $Q_{T}$ respectively. These figures are obtained with a mesh $\mathcal{T}_{h}$ composed of 9088 triangles and for which $h=2.46 \times 10^{-2}$. In agreement with Theorem 2.1, item (iii), $\lambda_{h}$ is an approximation of the controlled solution for (1). We have used here $r=10^{-2}$.

We also emphasize that this variational method which requires a finite element discretization of the time-space $Q_{T}$ is particularly well-adapted to mesh optimization. Still for the example EX3, Figure 7 depicts a sequence of five distinct meshes of $Q_{T}=(0,1) \times(0, T)$ : the sequence is initiated with a coarse and regularly distributed mesh, corresponding to $N=5$. The four other meshes are successively obtained by local refinement based on the norm of the gradient of $\lambda_{h}$ on each triangle of $\mathcal{T}_{h}$. As expected, the refinement is concentrated around the lines of discontinuity of $\lambda_{h}$ (see Figure $9^{\text {P }}$ traveling in $Q_{T}$, generated by the discontinuity of the initial position $y_{0}$. The five meshes

Figure 3: Example EX3; Evolution of $\left\|v-v_{h}\right\|_{L^{2}(0, T)}$ w.r.t. $h$ for BFS finite element ( $\star$ ), HCTuniform mesh (०) and HCT- non uniform mesh ( $\square$ ) $; r=1$.

Figure 4: Control of minimal $L^{2}$-norm $v$ and its approximation $v_{h}$ on $(0, T)$.

Figure 5: Example EX3 : The dual variable $\varphi_{h}$ in $Q_{T} ; h=2.46 \times 10^{-2} ; r=10^{-2}$.

Figure 6: Example EX3 : The primal variable $\lambda_{h}$ in $Q_{T} ; h=2.46 \times 10^{-2} ; r=10^{-2}$.
contain $142,412,1154,2556$ and 4750 triangles respectively. The number of nodes in these five meshes is $87,231,614,1324$ and 2429 respectively. The errors $\left\|v-v_{h}\right\|_{L^{2}(0, T)}$ corresponding to each of the five meshes (sorted by number of triangles) are : $2.67 \times 10^{-1}, 2.51 \times 10^{-1}, 1.31 \times 10^{-1}$, $8.36 \times 10^{-2}$ and $8.11 \times 10^{-2}$ respectively.

As a partial conclusion, this direct method offers very good approximations of the control of minimal square-integrable norm, even in singular situations for which classical methods generally fail. It is important to note that the lack of uniform property we have suspected (for $r$ fixed and large enough) from the experiences reported in Section 4.2 does not seem to have a significant influence on the behavior of the method w.r.t. $h$. For any $r>0$, the convergence of the approximation is observed as $h$ tends to 0 . An intermediate value of $r$, around $10^{-2}$, offers a good compromise between the convergence of the primal variable $\lambda_{h}$ and of the dual one $\varphi_{h}$. In this respect, the parameter $r$ may not be seen as an augmentation parameter for the Lagrangian $\mathcal{L}$, but rather as a regularization parameter for the variable $\varphi_{h}$ (this enforces $L \varphi_{h} \in L^{2}\left(Q_{T}\right)$ uniformly). This also suggests that the constraint $L \varphi \in L^{2}\left(Q_{T}\right)$ we have settled in the definition of the space $W$ (see 18 may possibly be weakened.

### 4.4 Conjugate gradient for $J^{\star \star}$

We illustrate here the Section 2.2 we minimize the functional $J^{\star \star}: L^{2}\left(Q_{T}\right) \rightarrow \mathbb{R}$ with respect to the variable $\lambda$. We recall that this minimization corresponds exactly to the resolution of the mixed formulation 20 by an iterative Uzawa type procedure. The conjugate gradient algorithm is given at the end of Section 2.2 . In practice, each iteration amounts to solve a linear system involving the matrix $A_{r, h}$ of size $n_{h}=4 m_{h}$ (see (39) which is sparse, symmetric and positive definite. We use the Cholesky method.

We consider the singular situation given by the example EX3. We take $\varepsilon=10^{-10}$ as a stopping threshold for the algorithm (that is the algorithm is stopped as soon as the norm of the residue $g^{n}$ at the iterate $n$ satisfies $\left.\left\|g^{n}\right\|_{L^{2}\left(Q_{T}\right)} \leq 10^{-10}\left\|g^{0}\right\|_{L^{2}\left(Q_{T}\right)}\right)$. The algorithm is initiated with $\lambda^{0}=0$ in $Q_{T}$.

We discuss only some results obtained with the BFS finite element (the HCT finite element leads to very similar results) and consider uniform meshes with $\Delta t=1.2 \Delta x$ (in order to emphasize that, in this finite element framework, it is absolutely not necessary to consider $\Delta t \leq \Delta x$ when the velocity $c$ of the waves equals one). Tables 17,18 and 19 display the result for $r=10^{-2}, 1$ and $r=10^{2}$ respectively. We recall that the norm of the control is $\|v\|_{L^{2}(0, T)} \approx 0.5773$.

We first check that this iterative method gives exactly the same approximation $\lambda_{h}$ than the previous direct method (where (39) is solved directly), since problem (20) coincides with the minimization of $J^{\star \star}$ in the sense given by Proposition 2.2 for $r>0$. Then, we observe that the number of iterates is sub-linear with respect to $h$, precisely with respect to the dimension $m_{h}=\operatorname{card}\left(\left\{\lambda_{h}\right\}\right)$ of the approximated problem. Once again, this is in contrast with the behavior of the conjugate gradient algorithm when this latter is used to minimize $J^{\star}$ with respect to $\left(\varphi_{0}, \varphi_{1}\right)$ (see 30). Finally, as for the direct method, the influence of the parameter $r$ remains limited. Since the gradient of $J^{\star \star}$ is given by $\nabla J^{\star \star}(\lambda)=L \varphi_{0}-A_{r} \lambda:=L \varphi$, a larger $r$ reduces the number of iterates. From this perspective, $r$ can be seen, here, as an augmentation parameter for the constraint $L \varphi=0$. On the other hand, a larger reduces the convergence of the primal variable, that is $\lambda_{h}$, and therefore of the control, defined here as the trace $\lambda_{h}(1, \cdot)$. For $r=1$ and the discretization corresponding to $h=9.99 \times 10^{-3}$ (that is $\Delta x=6.25 \times 10^{-2}, \Delta t=7.79 \times 10^{-2}$ ), Figure 10 depicts the evolution of the ratio $\left\|g^{n}\right\|_{L^{2}\left(Q_{T}\right)} /\left\|g^{0}\right\|_{L^{2}\left(Q_{T}\right)}$ with respect to the iterates and illustrates the remarkable robustness of the method.

Figure 7: Example EX3 - Iterative refinement of the triangular mesh over $Q_{T}$ with respect to the variable $\lambda_{h}: 142,412,1154,2556,4750$ triangles; $r=2 \times 10^{-3}$.

### 4.5 Numerical experiments: the inner case

We illustrate numerically the Section 3 which concerns the distributed controllability. Following Remark 2 and in order to avoid scalar product over $H^{-1}$, we solve the mixed formulation 35 and look for $\varphi$ such that $L \varphi$ belongs to $L^{2}\left(Q_{T}\right)$. In this case, the numerical implementation of the distributed case is very similar to the boundary one : the term $\int_{0}^{T} c(1) \varphi_{x}(1, \cdot) \bar{\varphi}_{x}(1, \cdot) d t$ is simply replaced by the term $\iint_{q_{T}} \varphi \bar{\varphi} d x d t$. The other difference appears in the linear right hand side term of the mixed formulation due to the change of regularity of the initial data.

We consider the following data (see [11], Section 4.5):

$$
(\mathbf{E X 4}) \quad y_{0}(x)=e^{-500(x-0.2)^{2}}, \quad y_{1}(x)=0, \quad T=2.2, \quad \omega=(0.2,0.4)
$$

and a non-constant function $c=c(x) \in C^{1}([0,1])$ with

$$
c(x)=\left\{\begin{array}{lll}
1 . & x \in[0,0.45]  \tag{42}\\
\in[1 ., 5 .] & \left(a^{\prime}(x)>0\right), & x \in(0.45,0.55) \\
5 . & x \in[0.55,1]
\end{array}\right.
$$

We refine iteratively the mesh, using as before a criterion based on the gradient of $\lambda_{h}$. Figure 11 (left) depicts the mesh obtained after 3 iterations. Again, the characteristic lines, starting from $x=0.2$ (where the initial position $y_{0}$ is mainly concentrated), may be observed on the figure. The corresponding approximation $\lambda_{h}$ is represented on Figure 11 (right). For this simulation we have used $r=2 \times 10^{-3}$. Table 20 gathers some informations on the successive meshes.

Figure 11: Example EX4 : Left : Triangular mesh of $q_{T}$ and of $Q_{T}$. Right : The primal variable $\lambda_{h}$ in $Q_{T}$.

Table 20: Example EX3 - Information on the successive meshes : the iterate 3 corresponds to the mesh of Figure 11.

## 5 Concluding remarks and perspectives

The mixed formulation we have introduced here in order to address the null controllability of the wave equation seems original. This formulation is nothing else than the Euler system associated to the conjugate functional and depends on both the dual adjoint variable and a Lagrange multiplier, which turns out to be the primal state of the wave equation to be controlled. The approach, recently used in a different way in [11, leads to a variational problem defined over time-space functional Hilbert spaces, without distinction between the time and the space variable. The main ingredients allowing to prove the well-posedness of the mixed formulation are an observability inequality, assuming here that $T$ is large enough, and a direct inequality (also called the hidden regularity inequality). For these reasons, the mixed reformulation may also be employed to any other controllable systems for which such inequalities are available : we mention notably the parabolic case (in particular [16] where a variational approach is used for the heat equation), usually badly conditioned and for which direct robust methods are certainly very advantageous.

At the practical level, the discrete mixed time-space formulation is solved in a systematic way in the framework of the finite element theory: in contrast to the classical approach initially developed in [19], there is no need to take care of the time discretization nor of the stability of the resulting scheme, which is often a delicate issue. The resolution amounts to solve a sparse symmetric linear system : the corresponding matrix can be preconditioned if necessary, and may be computed once for all as it does not depend on the initial data to be controlled. Eventually, the space-time discretization of the domain allows an adaptation of the mesh so as to reduce the computational cost and capture the main features of the solutions.

For this reason, it is also worthwhile to remark that the variational approach developed here based on a space-time formulation allows to consider in a systematic way the case where the support of inner controls evolves in time. We refer to the work [6] where observability and controllability results are obtained for point-wise moving controls. Actually, using results from [6], we may extend the mixed formulation (35) and in particular prove, assuming $T$ large enough, that the generalized observability inequality (36) also holds for control support of the form

$$
q_{T}:=\left\{(x, t) \in Q_{T} ; \quad \gamma(t)-\gamma_{1}(t)<x<\gamma(t)+\gamma_{2}(t), \quad t \in(0, T)\right\}
$$

where $\gamma$ denotes any curve in the appropriate class defined in [6] and $\gamma_{1}, \gamma_{2}$ any functions in $C\left([0, T], \mathbb{R}_{\star}^{+}\right)$. This issue as well as the optimization of the domain $q_{T}$ (leading to the control of minimal $L^{2}\left(q_{T}\right)$-norm, in the spirit of the work [32]) is fully discussed in [7].

Eventually, let us mention that upon classical conditions on the support of the control (distributed or located on a part of the boundary) and on the controllability time as discussed in [2, 27], the approach developed in this work remains valid in any dimension in space.
