Abstract

We analyze rigorously error estimates and compare numerically spatial/temporal resolution of various numerical methods for the discretization of the Dirac equation in the nonrelativistic limit regime, involving a small dimensionless parameter $0 < \varepsilon \ll 1$ which is inversely proportional to the speed of light. In this limit regime, the solution is highly oscillatory in time, i.e. there are propagating waves with wavelength $O(\varepsilon^2)$ and $O(1)$ in time and space, respectively. We begin with several frequently used finite difference time domain (FDTD) methods and obtain rigorously their error estimates in the nonrelativistic limit regime by paying particular attention to how error bounds depend explicitly on mesh size h and time step τ as well as the small parameter ε . Based on the error bounds, in order to obtain ‘correct’ numerical solutions in the nonrelativistic limit regime, i.e. $0 < \varepsilon \ll 1$, the FDTD methods share the same ε -scalability on time step and mesh size as: $\tau = O(\varepsilon^3)$ and $h = O(\sqrt{\varepsilon})$. Then we propose and analyze two numerical methods for the discretization of the Dirac equation by using the Fourier spectral discretization for spatial derivatives combined with the exponential wave integrator and time-splitting technique for temporal derivatives, respectively. Rigorous error bounds for the two numerical methods show that their ε -scalability is improved to $\tau = O(\varepsilon^2)$ and $h = O(1)$ when $0 < \varepsilon \ll 1$. Extensive numerical results are reported to support our error estimates.

Keywords: Dirac equation, nonrelativistic limit regime, finite difference time domain method, exponential wave integrator spectral method, time splitting spectral method, ε -scalability

1. Introduction

The Dirac equation, which plays an important role in particle physics, is a relativistic wave equation derived by the British physicist Paul Dirac in 1928 [28, 29, 30, 73]. It provided a description of elementary spin-1/2 massive particles, such as electrons and positrons, consistent with both the principle of quantum mechanics and the theory of special relativity. It was the first theory to fully account for relativity in the context of quantum mechanics. It addressed the fine details of the hydrogen spectrum in a completely rigorous way and predicted the existence of a new form of matter, antimatter [4]. Since the graphene was first produced in the lab in 2003 [1, 61, 62, 63, 65], the Dirac equation has been extensively adopted to study theoretically the structures and/or dynamical properties of graphene and graphite as well as two

dimensional (2D) materials [60]. This experimental advance renewed extensively the research interests on the mathematical analysis and numerical simulations of the Dirac equation and/or the (nonlinear) Schrödinger equation without/with external potentials, especially the honeycomb lattice potential [3, 35].

We consider the three dimensional (3D) Dirac equation for describing the time evolution of spin-1/2 massive particles, such as electrons and positrons, within external time-dependent electromagnetic potentials [28, 29]

$$i\hbar\partial_t\Psi(t, \mathbf{x}) = \left[-i\hbar\sum_{j=1}^3\alpha_j\partial_j + mc^2\beta\right]\Psi(t, \mathbf{x}) + e\left[V(t, \mathbf{x})I_4 - \sum_{j=1}^3A_j(t, \mathbf{x})\alpha_j\right]\Psi(t, \mathbf{x}). \quad (1.1)$$

Here, $i = \sqrt{-1}$, t is time, $\mathbf{x} = (x_1, x_2, x_3)^T \in \mathbb{R}^3$ (equivalently written as $\mathbf{x} = (x, y, z)^T$) is the spatial coordinate vector, $\partial_k = \frac{\partial}{\partial x_k}$ ($k = 1, 2, 3$), $\Psi := \Psi(t, \mathbf{x}) = (\psi_1(t, \mathbf{x}), \psi_2(t, \mathbf{x}), \psi_3(t, \mathbf{x}), \psi_4(t, \mathbf{x}))^T \in \mathbb{C}^4$ is the complex-valued vector wave function of the ‘‘spinorfield’’. I_n is the $n \times n$ identity matrix for $n \in \mathbb{N}$, $V := V(t, \mathbf{x})$ is the real-valued electrical potential and $\mathbf{A} := \mathbf{A}(t, \mathbf{x}) = (A_1(t, \mathbf{x}), A_2(t, \mathbf{x}), A_3(t, \mathbf{x}))^T$ is the real-valued magnetic potential vector, and hence the electric field is given by $\mathbf{E}(t, \mathbf{x}) = -\nabla V - \partial_t\mathbf{A}$ and the magnetic field is given by $\mathbf{B}(t, \mathbf{x}) = \text{curl}\mathbf{A} = \nabla \times \mathbf{A}$. The physical constants are: c for the speed of light, m for the particle’s rest mass, \hbar for the Planck constant and e for the unit charge. In addition, the 4×4 matrices $\alpha_1, \alpha_2, \alpha_3$ and β are defined as

$$\alpha_1 = \begin{pmatrix} \mathbf{0} & \sigma_1 \\ \sigma_1 & \mathbf{0} \end{pmatrix}, \quad \alpha_2 = \begin{pmatrix} \mathbf{0} & \sigma_2 \\ \sigma_2 & \mathbf{0} \end{pmatrix}, \quad \alpha_3 = \begin{pmatrix} \mathbf{0} & \sigma_3 \\ \sigma_3 & \mathbf{0} \end{pmatrix}, \quad \beta = \begin{pmatrix} I_2 & \mathbf{0} \\ \mathbf{0} & -I_2 \end{pmatrix}, \quad (1.2)$$

with $\sigma_1, \sigma_2, \sigma_3$ (equivalently written $\sigma_x, \sigma_y, \sigma_z$) being the Pauli matrices defined as

$$\sigma_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \sigma_2 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}. \quad (1.3)$$

In order to scale the Dirac equation (1.1), we introduce

$$\tilde{t} = \frac{t}{t_s}, \quad \tilde{\mathbf{x}} = \frac{\mathbf{x}}{x_s}, \quad \tilde{\Psi}(\tilde{t}, \tilde{\mathbf{x}}) = x_s^{3/2}\Psi(t, \mathbf{x}), \quad \tilde{V}(\tilde{t}, \tilde{\mathbf{x}}) = \frac{V(t, \mathbf{x})}{A_s}, \quad \tilde{A}_j(\tilde{t}, \tilde{\mathbf{x}}) = \frac{A_j(t, \mathbf{x})}{A_s}, \quad j = 1, 2, 3, \quad (1.4)$$

where x_s, t_s and A_s are the dimensionless length unit, time unit and potential unit, respectively, satisfying $t_s = \frac{mx_s^2}{\hbar}$ and $A_s = \frac{mv^2}{e}$ with $v = \frac{x_s}{t_s}$ being the wave speed. Plugging (1.4) into (1.1), multiplying by $\frac{t_s x_s^{3/2}}{\hbar}$, and then removing all $\tilde{\cdot}$, we obtain the following dimensionless Dirac equation in 3D

$$i\partial_t\Psi(t, \mathbf{x}) = \left[-\frac{i}{\varepsilon}\sum_{j=1}^3\alpha_j\partial_j + \frac{1}{\varepsilon^2}\beta\right]\Psi(t, \mathbf{x}) + \left[V(t, \mathbf{x})I_4 - \sum_{j=1}^3A_j(t, \mathbf{x})\alpha_j\right]\Psi(t, \mathbf{x}), \quad \mathbf{x} \in \mathbb{R}^3, \quad (1.5)$$

where ε is a dimensionless parameter inversely proportional to the speed of light given by

$$0 < \varepsilon := \frac{x_s}{t_s c} = \frac{v}{c} \leq 1. \quad (1.6)$$

We remark here that if one chooses the dimensionless length unit $x_s = \frac{\hbar}{mc}$, $t_s = \frac{x_s}{c}$ and $A_s = \frac{mc^2}{e}$ in (1.4), then $\varepsilon = 1$ in (1.6) and Eq. (1.5) with $\varepsilon = 1$ takes the form often appearing in the literature [2, 17, 21, 23, 33, 39, 47, 51]. This choice of x_s is appropriate when the wave speed is at the same order of the speed of light. However, when the wave speed is much smaller than the speed of light, a different choice of x_s is more appropriate. Note that the choice of x_s determines the observation scale of the time evolution of the particles and decides: (i) which phenomena are ‘visible’ by asymptotic analysis, and (ii) which phenomena can be resolved by discretization by specified spatial/temporal grids. In fact, there are two important parameter regimes: One is $\varepsilon = 1$ ($\iff x_s = \frac{\hbar}{mc}, t_s = \frac{x_s}{c}$ and $A_s = \frac{mc^2}{e}$), then Eq. (1.5) describes the case that wave speed is at the same order of the speed of light; the other one is $0 < \varepsilon \ll 1$, then Eq. (1.5) is in the nonrelativistic limit regime.

Similarly to the dimension reduction of the nonlinear Schrödinger equation and/or the Schrödinger-Poisson equations with/without anisotropic external potentials [8], when the initial data $\Psi(0, \mathbf{x})$ and the electromagnetic potentials $V(t, \mathbf{x})$ and $\mathbf{A}(t, \mathbf{x})$ are independent of z and thus the wave function Ψ is formally assumed to be independent of z , or when the electromagnetic potentials $V(t, \mathbf{x})$ and $\mathbf{A}(t, \mathbf{x})$ are strongly confined in the z -direction and thus Ψ is formally assumed to be concentrated on the xy -plane, then the 3D Dirac equation (1.5) can be reduced to the Dirac equation in 2D with $\mathbf{x} = (x, y)^T \in \mathbb{R}^2$ as

$$i\partial_t\Psi(t, \mathbf{x}) = \left[-\frac{i}{\varepsilon} \sum_{j=1}^2 \alpha_j \partial_j + \frac{1}{\varepsilon^2} \beta\right] \Psi(t, \mathbf{x}) + \left[V(t, \mathbf{x})I_4 - \sum_{j=1}^2 A_j(t, \mathbf{x})\alpha_j\right] \Psi(t, \mathbf{x}), \quad \mathbf{x} \in \mathbb{R}^2. \quad (1.7)$$

This 2D Dirac equation has been widely used to model the electron structure and/or dynamical properties of graphene since they share the same dispersion relation on the Dirac points [1, 61, 62, 63, 65, 35, 36, 37]. Similarly, under the proper assumptions on the initial data and the external electromagnetic potential, the 3D Dirac equation (1.5) can be reduced to the Dirac equation in 1D with $\Psi = \Psi(t, x)$ as

$$i\partial_t\Psi(t, x) = \left[-\frac{i}{\varepsilon} \alpha_1 \partial_x + \frac{1}{\varepsilon^2} \beta\right] \Psi(t, x) + \left[V(t, x)I_4 - A_1(t, x)\alpha_1\right] \Psi(t, x), \quad x \in \mathbb{R}. \quad (1.8)$$

In fact, the Dirac equation in 3D (1.5), in 2D (1.7) and in 1D (1.8) can be written in a unified way in d -dimensions ($d = 1, 2, 3$)

$$i\partial_t\Psi(t, \mathbf{x}) = \left[-\frac{i}{\varepsilon} \sum_{j=1}^d \alpha_j \partial_j + \frac{1}{\varepsilon^2} \beta\right] \Psi(t, \mathbf{x}) + \left[V(t, \mathbf{x})I_4 - \sum_{j=1}^d A_j(t, \mathbf{x})\alpha_j\right] \Psi(t, \mathbf{x}), \quad \mathbf{x} \in \mathbb{R}^d, \quad (1.9)$$

and the initial condition for dynamics is given as

$$\Psi(t = 0, \mathbf{x}) = \Psi_0(\mathbf{x}), \quad \mathbf{x} \in \mathbb{R}^d. \quad (1.10)$$

The Dirac equation (1.9) is dispersive and time symmetric. Introducing the position density ρ_j for the j -component ($j = 1, 2, 3, 4$) and the total density ρ as well as the current density $\mathbf{J}(t, \mathbf{x}) = (J_1(t, \mathbf{x}), J_2(t, \mathbf{x}), J_3(t, \mathbf{x}))^T$

$$\rho(t, \mathbf{x}) = \sum_{j=1}^4 \rho_j(t, \mathbf{x}) = \Psi^* \Psi, \quad \rho_j(t, \mathbf{x}) = |\psi_j(t, \mathbf{x})|^2, \quad 1 \leq j \leq 4; \quad J_l(t, \mathbf{x}) = \frac{1}{\varepsilon} \Psi^* \alpha_l \Psi, \quad l = 1, 2, 3, \quad (1.11)$$

where \bar{f} denotes the complex conjugate of f and $\Psi^* = \bar{\Psi}^T$, then the following conservation law can be obtained from the Dirac equation (1.9)

$$\partial_t \rho(t, \mathbf{x}) + \nabla \cdot \mathbf{J}(t, \mathbf{x}) = 0, \quad \mathbf{x} \in \mathbb{R}^d, \quad t \geq 0. \quad (1.12)$$

Thus the Dirac equation (1.9) conserves the total mass as

$$\|\Psi(t, \cdot)\|^2 := \int_{\mathbb{R}^d} |\Psi(t, \mathbf{x})|^2 d\mathbf{x} = \int_{\mathbb{R}^d} \sum_{j=1}^4 |\psi_j(t, \mathbf{x})|^2 d\mathbf{x} \equiv \|\Psi(0, \cdot)\|^2 = \|\Psi_0\|^2, \quad t \geq 0. \quad (1.13)$$

If the electric potential V is perturbed by a real constant V^0 , e.g. $V(t, \mathbf{x}) \rightarrow V(t, \mathbf{x}) + V^0$, then the solution $\Psi(t, \mathbf{x}) \rightarrow e^{-iV^0 t} \Psi(t, \mathbf{x})$ which implies the density of each component ρ_j ($j = 1, 2, 3, 4$) and the total density ρ unchanged. When $d = 1$, if the magnetic potential A_1 is perturbed by a real constant A_1^0 , e.g. $A_1(t, \mathbf{x}) \rightarrow A_1(t, \mathbf{x}) + A_1^0$, then the solution $\Psi(t, \mathbf{x}) \rightarrow e^{iA_1^0 t \alpha_1} \Psi(t, \mathbf{x})$ which implies the total density ρ unchanged; but this property is not valid when $d = 2, 3$. In addition, when the electromagnetic potentials are

time-independent, i.e. $V(t, \mathbf{x}) = V(\mathbf{x})$ and $A_j(t, \mathbf{x}) = A_j(\mathbf{x})$ for $j = 1, 2, 3$, the following energy functional is also conserved

$$E(t) := \int_{\mathbb{R}^d} \left(-\frac{i}{\varepsilon} \sum_{j=1}^d \Psi^* \alpha_j \partial_j \Psi + \frac{1}{\varepsilon^2} \Psi^* \beta \Psi + V(\mathbf{x}) |\Psi|^2 - \sum_{j=1}^d A_j(\mathbf{x}) \Psi^* \alpha_j \Psi \right) d\mathbf{x} \equiv E(0), \quad t \geq 0. \quad (1.14)$$

Furthermore, if the external electromagnetic potentials are constants, i.e. $V(t, \mathbf{x}) \equiv V^0$ and $A_j(t, \mathbf{x}) \equiv A_j^0$ for $j = 1, 2, 3$ with $\mathbf{A}^0 = (A_1^0, \dots, A_d^0)^T$, the Dirac equation (1.9) admits the plane wave solution as $\Psi(t, \mathbf{x}) = \mathbf{B} e^{i(\mathbf{k} \cdot \mathbf{x} - \omega t)}$, where the time frequency ω , amplitude vector $\mathbf{B} \in \mathbb{R}^4$ and spatial wave number $\mathbf{k} = (k_1, \dots, k_d)^T \in \mathbb{R}^d$ satisfy the following *dispersion relation*

$$\omega \mathbf{B} = \left[\sum_{j=1}^d \left(\frac{k_j}{\varepsilon} - A_j^0 \right) \alpha_j + \frac{1}{\varepsilon^2} \beta + V^0 I_4 \right] \mathbf{B}, \quad (1.15)$$

which immediately implies the dispersion relation of the Dirac equation (1.9) as

$$\omega := \omega(\mathbf{k}) = V^0 \pm \frac{1}{\varepsilon^2} \sqrt{1 + \varepsilon^2 |\mathbf{k} - \varepsilon \mathbf{A}^0|^2}, \quad \mathbf{k} \in \mathbb{R}^d. \quad (1.16)$$

Plugging (1.2) and (1.3) into (1.7), the 2D Dirac equation (1.7) can be decoupled as

$$\begin{aligned} i\partial_t \psi_1 &= -\frac{i}{\varepsilon} (\partial_x - i\partial_y) \psi_4 + \frac{1}{\varepsilon^2} \psi_1 + V(t, \mathbf{x}) \psi_1 - [A_1(t, \mathbf{x}) - iA_2(t, \mathbf{x})] \psi_4, \\ i\partial_t \psi_4 &= -\frac{i}{\varepsilon} (\partial_x + i\partial_y) \psi_1 - \frac{1}{\varepsilon^2} \psi_4 + V(t, \mathbf{x}) \psi_4 - [A_1(t, \mathbf{x}) + iA_2(t, \mathbf{x})] \psi_1, \quad \mathbf{x} \in \mathbb{R}^2, \end{aligned} \quad (1.17)$$

$$\begin{aligned} i\partial_t \psi_2 &= -\frac{i}{\varepsilon} (\partial_x + i\partial_y) \psi_3 + \frac{1}{\varepsilon^2} \psi_2 + V(t, \mathbf{x}) \psi_2 - [A_1(t, \mathbf{x}) + iA_2(t, \mathbf{x})] \psi_3, \\ i\partial_t \psi_3 &= -\frac{i}{\varepsilon} (\partial_x - i\partial_y) \psi_2 - \frac{1}{\varepsilon^2} \psi_3 + V(t, \mathbf{x}) \psi_3 - [A_1(t, \mathbf{x}) - iA_2(t, \mathbf{x})] \psi_2, \quad \mathbf{x} \in \mathbb{R}^2. \end{aligned} \quad (1.18)$$

Eq. (1.18) will collapse to (1.17) under the transformation $y \rightarrow -y$ and $A_2 \rightarrow -A_2$. Thus, in 2D, the Dirac equation (1.7) can be reduced to the following simplified PDEs with $\Phi = \Phi(t, \mathbf{x}) = (\phi_1(t, \mathbf{x}), \phi_2(t, \mathbf{x}))^T \in \mathbb{C}^2$

$$i\partial_t \Phi(t, \mathbf{x}) = \left[-\frac{i}{\varepsilon} (\sigma_1 \partial_x + \sigma_2 \partial_y) + \frac{1}{\varepsilon^2} \sigma_3 \right] \Phi(t, \mathbf{x}) + \left[V(t, \mathbf{x}) I_2 - A_1(t, \mathbf{x}) \sigma_1 - A_2(t, \mathbf{x}) \sigma_2 \right] \Phi(t, \mathbf{x}), \quad \mathbf{x} \in \mathbb{R}^2, \quad (1.19)$$

where $\Phi = (\psi_1, \psi_4)^T$ (or $\Phi = (\psi_2, \psi_3)^T$ under the transformation $y \rightarrow -y$ and $A_2 \rightarrow -A_2$). Similarly, in 1D, the Dirac equation (1.8) can be reduced to the following simplified PDEs with $\Phi = \Phi(t, x) = (\phi_1(t, x), \phi_2(t, x))^T$

$$i\partial_t \Phi(t, x) = \left[-\frac{i}{\varepsilon} \sigma_1 \partial_x + \frac{1}{\varepsilon^2} \sigma_3 \right] \Phi(t, x) + \left[V(t, x) I_2 - A_1(t, x) \sigma_1 \right] \Phi(t, x), \quad x \in \mathbb{R}, \quad (1.20)$$

where $\Phi = (\psi_1, \psi_4)^T$ (or $\Phi = (\psi_2, \psi_3)^T$). Again, the Dirac equation in 2D (1.19) and in 1D (1.20) can be written in a unified way in d -dimensions ($d = 1, 2$)

$$i\partial_t \Phi(t, \mathbf{x}) = \left[-\frac{i}{\varepsilon} \sum_{j=1}^d \sigma_j \partial_j + \frac{1}{\varepsilon^2} \sigma_3 \right] \Phi(t, \mathbf{x}) + \left[V(t, \mathbf{x}) I_2 - \sum_{j=1}^d A_j(t, \mathbf{x}) \sigma_j \right] \Phi(t, \mathbf{x}), \quad \mathbf{x} \in \mathbb{R}^d, \quad (1.21)$$

and the initial condition for dynamics is given as

$$\Phi(t = 0, \mathbf{x}) = \Phi_0(\mathbf{x}), \quad \mathbf{x} \in \mathbb{R}^d. \quad (1.22)$$

The Dirac equation (1.21) is dispersive and time symmetric. By introducing the position density ρ_j for the j -th component ($j = 1, 2$) and the total density ρ as well as the current density $\mathbf{J}(t, \mathbf{x}) = (J_1(t, \mathbf{x}), J_2(t, \mathbf{x}))^T$

$$\rho(t, \mathbf{x}) = \sum_{j=1}^2 \rho_j(t, \mathbf{x}) = \Phi^* \Phi, \quad \rho_j(t, \mathbf{x}) = |\phi_j(t, \mathbf{x})|^2, \quad J_j(t, \mathbf{x}) = \frac{1}{\varepsilon} \Phi^* \sigma_j \Phi, \quad j = 1, 2, \quad (1.23)$$

the conservation law (1.12) is also satisfied [23]. In addition, the Dirac equation (1.21) conserves the total mass as

$$\|\Phi(t, \cdot)\|^2 := \int_{\mathbb{R}^d} |\Phi(t, \mathbf{x})|^2 d\mathbf{x} = \int_{\mathbb{R}^d} \sum_{j=1}^2 |\phi_j(t, \mathbf{x})|^2 d\mathbf{x} \equiv \|\Phi(0, \cdot)\|^2 = \|\Phi_0\|^2, \quad t \geq 0. \quad (1.24)$$

Again, if the electric potential V is perturbed by a real constant V^0 , e.g. $V(t, \mathbf{x}) \rightarrow V(t, \mathbf{x}) + V^0$, the solution $\Phi(t, \mathbf{x}) \rightarrow e^{-iV^0 t} \Phi(t, \mathbf{x})$ which implies the density of each component ρ_j ($j = 1, 2$) and the total density ρ unchanged. When $d = 1$, if the magnetic potential A_1 is perturbed by a real constant A_1^0 , e.g. $A_1(t, \mathbf{x}) \rightarrow A_1(t, \mathbf{x}) + A_1^0$, the solution $\Phi(t, \mathbf{x}) \rightarrow e^{iA_1^0 t \sigma_1} \Phi(t, \mathbf{x})$ implying the total density ρ unchanged; but this property is not valid when $d = 2$. When the electromagnetic potentials are time-independent, i.e. $V(t, \mathbf{x}) = V(\mathbf{x})$ and $A_j(t, \mathbf{x}) = A_j(\mathbf{x})$ for $j = 1, 2$, the following energy functional is also conserved

$$E(t) := \int_{\mathbb{R}^d} \left(-\frac{i}{\varepsilon} \sum_{j=1}^d \Phi^* \sigma_j \partial_j \Phi + \frac{1}{\varepsilon^2} \Phi^* \sigma_3 \Phi + V(\mathbf{x}) |\Phi|^2 - \sum_{j=1}^d A_j(\mathbf{x}) \Phi^* \sigma_j \Phi \right) d\mathbf{x} \equiv E(0), \quad t \geq 0. \quad (1.25)$$

Furthermore, if the external electromagnetic potentials are constants, i.e. $V(t, \mathbf{x}) \equiv V^0$ and $A_j(t, \mathbf{x}) \equiv A_j^0$ for $j = 1, 2$, the Dirac equation (1.21) admits the plane wave solution as $\Phi(t, \mathbf{x}) = \mathbf{B} e^{i(\mathbf{k} \cdot \mathbf{x} - \omega t)}$, where the time frequency ω , amplitude vector $\mathbf{B} \in \mathbb{R}^2$ and spatial wave number $\mathbf{k} = (k_1, \dots, k_d)^T \in \mathbb{R}^d$ satisfy the following *dispersion relation*

$$\omega \mathbf{B} = \left[\sum_{j=1}^d \left(\frac{k_j}{\varepsilon} - A_j^0 \right) \sigma_j + \frac{1}{\varepsilon^2} \sigma_3 + V^0 I_2 \right] \mathbf{B}, \quad (1.26)$$

which again implies the dispersion relation (1.16) of the Dirac equation (1.21) for $d = 2, 1$.

For the Dirac equation (1.9) with $\varepsilon = 1$, i.e. $O(1)$ -speed of light regime, there are extensive analytical and numerical results in the literatures. For the existence and multiplicity of bound states and/or standing wave solutions, we refer to [32, 25, 26, 31, 42, 74] and references therein. For the analysis of the classical/semiclassical limits via the Wigner transform techniques, we refer to [41, 7, 20, 22, 55, 71, 67] and references therein. For the numerical methods and comparison such as the finite difference time domain (FDTD) methods and the Gaussian beam methods, we refer to [5, 7, 78, 77, 75, 27, 68, 75, 43] and references therein. However, for the Dirac equation (1.9) with $0 < \varepsilon \ll 1$, i.e. nonrelativistic limit regime (or the scaled speed of light goes to infinity), the analysis and efficient computation of the Dirac equation (1.9) (or (1.21)) are mathematically rather complicated. The main difficulty is due to that the solution is highly oscillatory in time and the corresponding energy functionals (1.14) and (1.25) are indefinite [18, 33] and become unbounded when $\varepsilon \rightarrow 0$. There are extensive mathematical analysis of the (semi)-nonrelativistic limit of the Dirac equation (1.9) to the Pauli equation [52, 19, 18, 24, 38, 44, 57, 58, 59, 66, 76] and/or the Schrödinger equation when $\varepsilon \rightarrow 0$ [18]. These rigorous analytical results show that the solution propagates waves with wavelength $O(\varepsilon^2)$ and $O(1)$ in time and space, respectively, when $0 < \varepsilon \ll 1$. In fact, the oscillatory structure of the solution of the Dirac equation (1.9) when $0 < \varepsilon \ll 1$ can be formally observed from its dispersion relation (1.15) (or (1.26)). To illustrate this further, Figure 1.1 shows the solution of the Dirac equation (1.21) with $d = 1$, $V(t, x) = \frac{1-x}{1+x^2}$, $A_1(t, x) = \frac{(1+x)^2}{1+x^2}$ and $\Phi_0(x) = (\exp(-x^2/2), \exp(-(x-1)^2/2))^T$ for different ε . This highly oscillatory nature of the solution of (1.9) (or (1.21)) causes severe numerical burdens in practical computation, making the numerical approximation of (1.9) (or (1.21)) extremely challenging and costly in

Figure 1.1: The solution $\phi_1(t = 1, x)$ and $\phi_1(t, x = 0)$ of the Dirac equation (1.21) with $d = 1$ for different ε . $\text{Re}(f)$ denotes the real part of f .

the nonrelativistic regime $0 < \varepsilon \ll 1$. In [51], the resolution of the time-splitting Fourier pseudospectral (TSFP) method was studied for the Maxwell-Dirac equation in the nonrelativistic limit regime.

Recently, different numerical methods were proposed and analyzed for the efficient computation of the Klein-Gordon equation in the nonrelativistic limit regime [11, 12, 34] and/or highly oscillatory dispersive partial differential equations (PDEs) [9, 10, 13, 14]. To our knowledge, so far there are few results on the numerics of the Dirac equation in the nonrelativistic limit regime. The aim of this paper is to study the efficiency of the frequently used FDTD and TSFP methods applied to the Dirac equation in the nonrelativistic limit regime, to propose the exponential wave integrator Fourier pseudospectral (EWI-FP) method and to compare their resolution capacities in this regime. We start with the detailed analysis on the stability and convergence of several standard implicit/semi-implicit/explicit FDTD methods [70]. Here we pay particular attention to how the error bounds depend explicitly on the small parameter ε in addition to the mesh size h and time step τ . Based on the estimates, in order to obtain ‘correct’ numerical approximations when $0 < \varepsilon \ll 1$, the meshing strategy requirement (ε -scalability) for those frequently used FDTD methods is: $h = O(\sqrt{\varepsilon})$ and $\tau = O(\varepsilon^3)$, which suggests that the standard FDTD methods are computationally expensive for the Dirac equation (1.9) as $0 < \varepsilon \ll 1$. To relax the ε -scalability, we then propose the EWI-FP method and compare it with the TSFP method, whose ε -scalability are optimal for both time and space in view of the inherent oscillatory nature. The key ideas of the EWI-FP are: (i) to apply the Fourier pseudospectral discretization for spatial derivatives; and (ii) to adopt the exponential wave integrator (EWI) for integrating the ordinary differential equations (ODEs) in phase space [40, 48] which was well demonstrated in the literatures that it has favorable properties compared to standard time integrators for oscillatory differential equations [40, 48, 49, 50]. Rigorous error estimates show that the ε -scalability of the EWI-FP method is $h = O(1)$, and $\tau = O(\varepsilon^2)$ for the Dirac equation with external electromagnetic potentials, meanwhile, the ε -scalability of TSFP method is $h = O(1)$ and $\tau = O(\varepsilon^2)$. Thus, the EWI-FP and TSFP offer compelling advantages over commonly used FDTD methods in temporal and spatial resolution when $0 < \varepsilon \ll 1$.

The rest of this paper is organized as follows. In Section 2, several second-order FDTD methods are reviewed and their stabilities and convergence are analyzed in the nonrelativistic limit regime. In Section 3, an exponential wave integrator Fourier pseudospectral method is proposed and analyzed rigorously. In Section 4, a time-splitting Fourier pseudospectral method is reviewed and analyzed rigorously. In Section 5, numerical comparison results are reported. Finally, some concluding remarks are drawn in Section 6. The mathematical proofs of the error estimates are given in the appendices, where extensions of EWI-FP and TSFP to higher dimensions are also presented. Throughout the paper, we adopt the standard notations of Sobolev spaces, use the notation $p \lesssim q$ to represent that there exists a generic constant C which is independent of h, τ and ε such that $|p| \leq Cq$.

2. FDTD methods and their analysis

In this section, we apply the commonly used FDTD methods to the Dirac equation (1.9) (or (1.21)) and analyze their stabilities and convergence in the nonrelativistic limit regime. For simplicity of notations, we shall only present the numerical methods and their analysis for (1.21) in 1D. Generalization to (1.9) and/or higher dimensions is straightforward and results remain valid without modifications. Similarly to most works in the literatures for the analysis and computation of the Dirac equation (cf. [17, 23, 46, 47, 51, 64, 77, 75] and references therein), in practical computation, we truncate the whole space problem onto an interval $\Omega = (a, b)$ with periodic boundary conditions, which is large enough such that the truncation error is negligible. In 1D, the Dirac equation (1.21) with periodic boundary conditions collapses to

$$i\partial_t\Phi(t, x) = \left[-\frac{i}{\varepsilon}\sigma_1\partial_x + \frac{1}{\varepsilon^2}\sigma_3\right]\Phi(t, x) + \left[V(t, x)I_2 - A_1(t, x)\sigma_1\right]\Phi(t, x), \quad x \in \Omega, \quad t > 0, \quad (2.1)$$

$$\Phi(t, a) = \Phi(t, b), \quad \partial_x\Phi(t, a) = \partial_x\Phi(t, b), \quad t \geq 0, \quad \Phi(0, x) = \Phi_0(x), \quad x \in \bar{\Omega}, \quad (2.2)$$

where $\Phi_0(a) = \Phi_0(b)$ and $\Phi'_0(a) = \Phi'_0(b)$.

2.1. FDTD methods

Choose mesh size $h := \Delta x = \frac{b-a}{M}$ with M being an even positive integer, time step $\tau := \Delta t > 0$ and denote the grid points and time steps as:

$$x_j := a + jh, \quad j = 0, 1, \dots, M; \quad t_n := n\tau, \quad n = 0, 1, 2, \dots$$

Denote $X_M = \{U = (U_0, U_1, \dots, U_M)^T \mid U_j \in \mathbb{C}^2, j = 0, 1, \dots, M, U_0 = U_M\}$ and we always use $U_{-1} = U_{M-1}$ and $U_{M+1} = U_1$ if they are involved. For any $U \in X_M$, we denote its Fourier representation as

$$U_j = \sum_{l=-M/2}^{M/2-1} \tilde{U}_l e^{i\mu_l(x_j-a)} = \sum_{l=-M/2}^{M/2-1} \tilde{U}_l e^{2ijl\pi/M}, \quad j = 0, 1, \dots, M, \quad (2.3)$$

where μ_l and $\tilde{U}_l \in \mathbb{C}^2$ are defined as

$$\mu_l = \frac{2l\pi}{b-a}, \quad \tilde{U}_l = \frac{1}{M} \sum_{j=0}^{M-1} U_j e^{-2ijl\pi/M}, \quad l = -\frac{M}{2}, \dots, \frac{M}{2} - 1. \quad (2.4)$$

The standard l^2 -norm in X_M is given as

$$\|U\|_{l^2}^2 = h \sum_{j=0}^{M-1} |U_j|^2, \quad U \in X_M. \quad (2.5)$$

Let Φ_j^n be the numerical approximation of $\Phi(t_n, x_j)$ and $V_j^n = V(t_n, x_j)$, $V_j^{n+1/2} = V(t_n + \tau/2, x_j)$, $A_{1,j}^n = A_1(t_n, x_j)$ and $A_{1,j}^{n+1/2} = A_1(t_n + \tau/2, x_j)$ for $0 \leq j \leq M$ and $n \geq 0$. Denote $\Phi^n = (\Phi_0^n, \Phi_1^n, \dots, \Phi_M^n)^T \in X_M$

as the solution vector at $t = t_n$. Introduce the finite difference discretization operators for $j = 0, 1, \dots, M$ and $n \geq 0$ as:

$$\delta_t^+ \Phi_j^n = \frac{\Phi_j^{n+1} - \Phi_j^n}{\tau}, \quad \delta_t \Phi_j^n = \frac{\Phi_j^{n+1} - \Phi_j^{n-1}}{2\tau}, \quad \delta_x \Phi_j^n = \frac{\Phi_{j+1}^n - \Phi_{j-1}^n}{2h}, \quad \Phi_j^{n+\frac{1}{2}} = \frac{\Phi_j^{n+1} + \Phi_j^n}{2}.$$

Here we consider several frequently used FDTD methods to discretize the Dirac equation (2.1) for $j = 0, 1, \dots, M-1$.

I. Leap-frog finite difference (LFFD) method

$$i\delta_t \Phi_j^n = \left[-\frac{i}{\varepsilon} \sigma_1 \delta_x + \frac{1}{\varepsilon^2} \sigma_3 \right] \Phi_j^n + \left[V_j^n I_2 - A_{1,j}^n \sigma_1 \right] \Phi_j^n, \quad n \geq 1. \quad (2.6)$$

II. Semi-implicit finite difference (SIFD1) method

$$i\delta_t \Phi_j^n = -\frac{i}{\varepsilon} \sigma_1 \delta_x \Phi_j^n + \frac{1}{\varepsilon^2} \sigma_3 \frac{\Phi_j^{n+1} + \Phi_j^{n-1}}{2} + \left[V_j^n I_2 - A_{1,j}^n \sigma_1 \right] \frac{\Phi_j^{n+1} + \Phi_j^{n-1}}{2}, \quad n \geq 1. \quad (2.7)$$

III. Another semi-implicit finite difference (SIFD2) method

$$i\delta_t \Phi_j^n = \left[-\frac{i}{\varepsilon} \sigma_1 \delta_x + \frac{1}{\varepsilon^2} \sigma_3 \right] \frac{\Phi_j^{n+1} + \Phi_j^{n-1}}{2} + \left[V_j^n I_2 - A_{1,j}^n \sigma_1 \right] \Phi_j^n, \quad n \geq 1. \quad (2.8)$$

IV. Crank-Nicolson finite difference (CNFD) method

$$i\delta_t^+ \Phi_j^n = \left[-\frac{i}{\varepsilon} \sigma_1 \delta_x + \frac{1}{\varepsilon^2} \sigma_3 \right] \Phi_j^{n+1/2} + \left[V_j^{n+1/2} I_2 - A_{1,j}^{n+1/2} \sigma_1 \right] \Phi_j^{n+1/2}, \quad n \geq 0. \quad (2.9)$$

The initial and boundary conditions in (2.2) are discretized as:

$$\Phi_M^{n+1} = \Phi_0^{n+1}, \quad \Phi_{-1}^{n+1} = \Phi_{M-1}^{n+1}, \quad n \geq 0, \quad \Phi_j^0 = \Phi_0(x_j), \quad j = 0, 1, \dots, M. \quad (2.10)$$

Using Taylor expansion and noticing (2.1), the first step for the LFFD (2.6), SIFD1 (2.7) and SIFD2 (2.8) can be computed as

$$\Phi_j^1 = \Phi_j^0 + \tau \left[-\frac{1}{\tau} \sin\left(\frac{\tau}{\varepsilon}\right) \sigma_1 \Phi_0'(x_j) - i \left(\frac{1}{\tau} \sin\left(\frac{\tau}{\varepsilon^2}\right) \sigma_3 + V_j^0 I_2 - A_{1,j}^0 \sigma_1 \right) \Phi_j^0 \right], \quad j = 0, 1, \dots, M. \quad (2.11)$$

In the above, we adapt $\frac{1}{\tau} \sin\left(\frac{\tau}{\varepsilon}\right)$ and $\frac{1}{\tau} \sin\left(\frac{\tau}{\varepsilon^2}\right)$ instead of $\frac{1}{\varepsilon}$ and $\frac{1}{\varepsilon^2}$ such that (2.11) is second order in term of τ for any fixed $0 < \varepsilon \leq 1$ and $\|\Phi^1\|_\infty := \max_{0 \leq j \leq M} |\Phi_j^1| \lesssim 1$ for $0 < \varepsilon \leq 1$. We remark here that they can be simply replaced by 1 when $\varepsilon = 1$.

The above four methods are all time symmetric, i.e. they are unchanged under $\tau \leftrightarrow -\tau$ and $n+1 \leftrightarrow n-1$ in the LFFD, SIFD1 and SIFD2 methods or $n+1 \leftrightarrow n$ in the CNFD method, and the memory cost is the same at $O(M)$. The LFFD method (2.6) is explicit and its computational cost per step is $O(M)$. In fact, it might be the simplest and most efficient discretization for the Dirac equation when $\varepsilon = 1$ and thus it has been widely used when $\varepsilon = 1$. The SIFD1 method (2.7) is implicit, however at each time step for $n \geq 1$, the corresponding linear system is decoupled and can be solved explicitly for $j = 0, 1, \dots, M-1$ as

$$\Phi_j^{n+1} = \left[(i - \tau V_j^n) I_2 - \frac{\tau}{\varepsilon^2} \sigma_3 + \tau A_{1,j}^n \sigma_1 \right]^{-1} \left[\left((i + \tau V_j^n) I_2 + \frac{\tau}{\varepsilon^2} \sigma_3 - \tau A_{1,j}^n \sigma_1 \right) \Phi_j^{n-1} - \frac{2i\tau}{\varepsilon} \sigma_1 \delta_x \Phi_j^n \right], \quad (2.12)$$

and thus its computational cost per step is $O(M)$.

The SIFD2 method (2.8) is implicit, however at each time step for $n \geq 1$, the corresponding linear system is decoupled in phase (Fourier) space and can be solved explicitly in phase space for $l = -M/2, \dots, M/2 - 1$ as

$$\widetilde{(\Phi^{n+1})}_l = \left(iI_2 - \frac{\tau \sin(\mu_l h)}{\varepsilon h} \sigma_1 - \frac{\tau}{\varepsilon^2} \sigma_3 \right)^{-1} \left[\left(iI_2 + \frac{\tau \sin(\mu_l h)}{\varepsilon h} \sigma_1 + \frac{\tau}{\varepsilon^2} \sigma_3 \right) \widetilde{(\Phi^{n-1})}_l + 2\tau \widetilde{(G^n \Phi^n)}_l \right], \quad (2.13)$$

where $G^n = (G_0^n, G_1^n, \dots, G_M^n)^T \in X_M$ with $G_j^n = -A_{1,j}^n \sigma_1 + V_j^n I_2$ for $j = 0, 1, \dots, M$, and thus its computational cost per step is $O(M \ln M)$. The CNFD method (2.9) is implicit and at each time step for $n \geq 0$, the corresponding linear system is coupled and needs to be solved via either a direct solver or an iterative solver, and thus its computational cost per step depends on the linear system solver, which is usually much larger than $O(M)$, especially in 2D and 3D. Based on the computational cost per time step, the LFFD method is the most efficient one and the CNFD method is the most expensive one.

2.2. Linear stability analysis

In order to carry out the linear stability analysis for the FDTD methods via the von Neumann method [70], we assume that $A_1(t, x) \equiv A_1^0$ and $V(t, x) \equiv V^0$ with A_1^0 and V^0 being two real constants in the Dirac equation (2.1). Then we have the following results for the FDTD methods:

Lemma 1. (i) *The LFFD method (2.6) is stable under the stability condition*

$$0 < \tau \leq \frac{\varepsilon^2 h}{|V^0| \varepsilon^2 h + \sqrt{h^2 + \varepsilon^2 (1 + \varepsilon h |A_1^0|)^2}}, \quad h > 0, \quad 0 < \varepsilon \leq 1. \quad (2.14)$$

(ii) *The SIFD1 method (2.7) is stable under the stability condition*

$$0 < \tau \leq \varepsilon h, \quad h > 0, \quad 0 < \varepsilon \leq 1. \quad (2.15)$$

(iii) *The SIFD2 method (2.8) is stable under the stability condition*

$$0 < \tau \leq \frac{1}{|V^0| + |A_1^0|}, \quad h > 0, \quad 0 < \varepsilon \leq 1. \quad (2.16)$$

(iv) *The CNFD method (2.9) is unconditionally stable, i.e. it is stable for any $\tau, h > 0$ and $0 < \varepsilon \leq 1$.*

Proof: (i) Plugging

$$\Phi_j^n = \sum_{l=-M/2}^{M/2-1} \xi_l^n \widetilde{(\Phi^0)}_l e^{i\mu_l(x_j - a)} = \sum_{l=-M/2}^{M/2-1} \xi_l^n \widetilde{(\Phi^0)}_l e^{2ijl\pi/M}, \quad j = 0, 1, \dots, M, \quad n \geq 0, \quad (2.17)$$

with $\xi_l \in \mathbb{C}$ and $\widetilde{(\Phi^0)}_l$ being the amplification factor and the Fourier coefficient at $n = 0$, respectively, of the l -th mode in the phase space into (2.6), using the orthogonality of the Fourier series, we obtain

$$\left| (\xi_l^2 - 1)I_2 - 2i\tau \xi_l \left(A_1^0 \sigma_1 - V^0 I_2 - \frac{1}{\varepsilon^2} \sigma_3 - \frac{\sin(\mu_l h)}{\varepsilon h} \sigma_1 \right) \right| = 0, \quad l = -\frac{M}{2}, \dots, \frac{M}{2} - 1. \quad (2.18)$$

Substituting (1.3) into (2.18), we get that the amplification factor ξ_l satisfies

$$\xi_l^2 - 2i\tau \theta_l \xi_l - 1 = 0, \quad l = -\frac{M}{2}, \dots, \frac{M}{2} - 1, \quad (2.19)$$

where

$$\theta_l = -V^0 \pm \frac{1}{\varepsilon^2 h} \sqrt{h^2 + \varepsilon^2 (A_1^0 \varepsilon h - \sin(\mu_l h))^2}, \quad l = -\frac{M}{2}, \dots, \frac{M}{2} - 1.$$

Then the stability condition for the LFFD method (2.6) becomes

$$|\xi_l| \leq 1 \iff |\tau\theta_l| \leq 1, \quad l = -\frac{M}{2}, \dots, \frac{M}{2} - 1, \quad (2.20)$$

which immediately implies the condition (2.14).

(ii) Similarly to (i), plugging (2.17) into the SIFD1 method (2.7), we have

$$\left| (\xi_l^2 - 1)I_2 - i\tau(\xi_l^2 + 1) \left(A_1^0\sigma_1 - V^0I_2 - \frac{1}{\varepsilon^2}\sigma_3 \right) + \frac{2i\tau\xi_l \sin(\mu_l h)}{\varepsilon h} \sigma_1 \right| = 0, \quad l = -\frac{M}{2}, \dots, \frac{M}{2} - 1. \quad (2.21)$$

Noticing (1.3), under the condition (2.15), we can get $|\xi_l| \leq 1$ for $l = -\frac{M}{2}, \dots, \frac{M}{2} - 1$, and thus it is stable.

(iii) Similarly to (i), plugging (2.17) into the SIFD2 method (2.8), we have

$$\left| (\xi_l^2 - 1)I_2 + i\tau(\xi_l^2 + 1) \left(\frac{1}{\varepsilon^2}\sigma_3 + \frac{\sin(\mu_l h)}{\varepsilon h} \sigma_1 \right) - 2i\tau\xi_l (A_1^0\sigma_1 - V^0I_2) \right| = 0, \quad l = -\frac{M}{2}, \dots, \frac{M}{2} - 1. \quad (2.22)$$

Noticing (1.3), under the condition (2.16), we obtain

$$|\xi_l| \leq 1, \quad l = -\frac{M}{2}, \dots, \frac{M}{2} - 1,$$

and thus it is stable.

(iv) Similarly to (i), plugging (2.17) into the CNFD method (2.9), we obtain

$$\left| (\xi_l - 1)I_2 + \frac{i\tau}{2}(\xi_l + 1) \left(\frac{1}{\varepsilon^2}\sigma_3 - A_1^0\sigma_1 - V^0I_2 + \frac{\sin(\mu_l h)}{\varepsilon h} \sigma_1 \right) \right| = 0, \quad l = -\frac{M}{2}, \dots, \frac{M}{2} - 1. \quad (2.23)$$

Noticing (1.3), we have for $l = -\frac{M}{2}, \dots, \frac{M}{2} - 1$,

$$|\xi_l| = \left| \frac{2 + i\tau\theta_l}{2 - i\tau\theta_l} \right| = 1, \quad \theta_l = V^0 \pm \frac{1}{\varepsilon^2 h} \sqrt{h^2 + \varepsilon^2 (A_1^0 \varepsilon h - \sin(\mu_l h))^2}. \quad (2.24)$$

Thus it is unconditionally stable. \square

2.3. Mass and energy conservation

For the CNFD method (2.9), we have the following conservative properties.

Lemma 2. *The CNFD (2.9) conserves the mass in the discretized level, i.e.*

$$\|\Phi^n\|_l^2 := h \sum_{j=0}^{M-1} |\Phi_j^n|^2 \equiv h \sum_{j=0}^{M-1} |\Phi_j^0|^2 = \|\Phi^0\|_l^2 = h \sum_{j=0}^{M-1} |\Phi_0(x_j)|^2, \quad n \geq 0. \quad (2.25)$$

Furthermore, if $V(t, x) = V(x)$ and $A_1(t, x) = A_1(x)$ are time independent, the CNFD (2.9) conserves the energy as well,

$$\begin{aligned} E_h^n &= -\frac{i\hbar}{\varepsilon} \sum_{j=1}^{M-1} (\Phi_j^n)^* \sigma_1 \delta_x \Phi_j^n + \frac{\hbar}{\varepsilon^2} \sum_{j=0}^{M-1} (\Phi_j^n)^* \sigma_3 \Phi_j^n + \hbar \sum_{j=0}^{M-1} V_j (\Phi_j^n)^* \sigma_3 \Phi_j^n - \hbar \sum_{j=0}^{M-1} A_{1,j} (\Phi_j^n)^* \sigma_1 \Phi_j^n \\ &\equiv E_h^0, \quad n \geq 0, \end{aligned} \quad (2.26)$$

where $V_j = V(x_j)$ and $A_{1,j} = A_1(x_j)$ for $j = 0, 1, \dots, M$.

Proof: (i) Firstly, we prove the mass conservation (2.25). Multiplying both sides of (2.9) from left by $h\tau(\Phi_j^{n+1/2})^*$ and taking the imaginary part, we have

$$h|\Phi_j^{n+1}|^2 = h|\Phi_j^n|^2 - \frac{\tau h}{2\varepsilon} \left[(\Phi_j^{n+1/2})^* \sigma_1 \delta_x \Phi_j^{n+1/2} + (\Phi_j^{n+1/2})^T \sigma_1 \delta_x \bar{\Phi}_j^{n+1/2} \right], \quad j = 0, 1, \dots, M-1. \quad (2.27)$$

Summing (2.27) for $j = 0, 1, \dots, M-1$ and noticing (1.3), we get

$$\begin{aligned} \|\Phi^{n+1}\|_{l^2}^2 &= \|\Phi^n\|_{l^2}^2 - \frac{\tau h}{2\varepsilon} \sum_{j=0}^{M-1} \left[(\Phi_j^{n+1/2})^* \sigma_1 \delta_x \Phi_j^{n+1/2} + (\Phi_j^{n+1/2})^T \sigma_1 \delta_x \bar{\Phi}_j^{n+1/2} \right] \\ &= \|\Phi^n\|_{l^2}^2 - \frac{\tau}{2\varepsilon} \sum_{j=0}^{M-1} \left[(\Phi_j^{n+1/2})^* \sigma_1 \Phi_{j+1}^{n+1/2} + (\Phi_j^{n+1/2})^T \sigma_1 \bar{\Phi}_{j+1}^{n+1/2} \right. \\ &\quad \left. - (\Phi_{j+1}^{n+1/2})^* \sigma_1 \Phi_j^{n+1/2} - (\Phi_{j+1}^{n+1/2})^T \sigma_1 \bar{\Phi}_j^{n+1/2} \right] \\ &= \|\Phi^n\|_{l^2}^2, \quad n \geq 0, \end{aligned} \quad (2.28)$$

which immediately implies (2.25) by induction.

(ii) Secondly, we prove the energy conservation (2.26). Multiplying both sides of (2.9) from left by $2h(\Phi_j^{n+1} - \Phi_j^n)^*$ and taking the real part, we have

$$\begin{aligned} -h \operatorname{Re} \left[\frac{i}{\varepsilon} (\Phi_j^{n+1} - \Phi_j^n)^* \sigma_1 \delta_x (\Phi_j^{n+1} + \Phi_j^n) \right] + \frac{h}{\varepsilon^2} \left[(\Phi_j^{n+1})^* \sigma_3 \Phi_j^{n+1} - (\Phi_j^n)^* \sigma_3 \Phi_j^n \right] \\ + hV_j(|\Phi_j^{n+1}|^2 - |\Phi_j^n|^2) - hA_{1,j} \left[(\Phi_j^{n+1})^* \sigma_1 \Phi_j^{n+1} - (\Phi_j^n)^* \sigma_1 \Phi_j^n \right] = 0. \end{aligned} \quad (2.29)$$

Summing (2.29) for $j = 0, 1, \dots, M-1$ and noticing the summation by parts formula, we have

$$h \sum_{j=0}^{M-1} \operatorname{Re} \left(\frac{i}{\varepsilon} (\Phi_j^{n+1} - \Phi_j^n)^* \sigma_1 \delta_x (\Phi_j^{n+1} + \Phi_j^n) \right) = \frac{ih}{\varepsilon} \sum_{j=0}^{M-1} (\Phi_j^{n+1})^* \sigma_1 \delta_x \Phi_j^{n+1} - \frac{ih}{\varepsilon} \sum_{j=0}^{M-1} (\Phi_j^n)^* \sigma_1 \delta_x \Phi_j^n,$$

and

$$\begin{aligned} -\frac{ih}{\varepsilon} \sum_{j=0}^{M-1} (\Phi_j^{n+1})^* \sigma_1 \delta_x \Phi_j^{n+1} + \frac{ih}{\varepsilon} \sum_{j=0}^{M-1} (\Phi_j^n)^* \sigma_1 \delta_x \Phi_j^n + \frac{h}{\varepsilon^2} \sum_{j=0}^{M-1} \left((\Phi_j^{n+1})^* \sigma_3 \Phi_j^{n+1} - (\Phi_j^n)^* \sigma_3 \Phi_j^n \right) \\ + h \sum_{j=0}^{M-1} V_j (|\Phi_j^{n+1}|^2 - |\Phi_j^n|^2) - h \sum_{j=0}^{M-1} A_{1,j} \left((\Phi_j^{n+1})^* \sigma_1 \Phi_j^{n+1} - (\Phi_j^n)^* \sigma_1 \Phi_j^n \right) = 0, \end{aligned} \quad (2.30)$$

which immediately implies (2.26). \square

2.4. Error estimates

Let $0 < T < T^*$ with T^* being the maximal existence time of the solution, and denote $\Omega_T = [0, T] \times \Omega$. Motivated by the nonrelativistic limit of the Dirac equation [18] and the dispersion relation (1.26), we assume that the exact solution of (2.1) satisfies $\Phi \in C^3([0, T]; (L^\infty(\Omega))^2) \cap C^2([0, T]; (W_p^{1,\infty}(\Omega))^2) \cap C^1([0, T]; (W_p^{2,\infty}(\Omega))^2) \cap C([0, T]; (W_p^{3,\infty}(\Omega))^2)$ and

$$(A) \quad \left\| \frac{\partial^{r+s}}{\partial t^r \partial x^s} \Phi \right\|_{L^\infty([0,T]; (L^\infty(\Omega))^2)} \lesssim \frac{1}{\varepsilon^{2r}}, \quad 0 \leq r \leq 3, \quad 0 \leq r+s \leq 3, \quad 0 < \varepsilon \leq 1, \quad (2.31)$$

where $W_p^{m,\infty}(\Omega) = \{u \mid u \in W^{m,\infty}(\Omega), \partial_x^l u(a) = \partial_x^l u(b), l = 0, \dots, m-1\}$ for $m \geq 1$ and here the boundary values are understood in the trace sense. In the subsequent discussion, we will omit Ω when referring to the

space norm taken on Ω . In addition, we assume the electromagnetic potentials $V \in C(\overline{\Omega}_T)$ and $A_1 \in C(\overline{\Omega}_T)$ and denote

$$(B) \quad V_{\max} := \max_{(t,x) \in \overline{\Omega}_T} |V(t,x)|, \quad A_{1,\max} := \max_{(t,x) \in \overline{\Omega}_T} |A_1(t,x)|. \quad (2.32)$$

Define the grid error function $\mathbf{e}^n = (\mathbf{e}_0^n, \mathbf{e}_1^n, \dots, \mathbf{e}_M^n)^T \in X_M$ as:

$$\mathbf{e}_j^n = \Phi(t_n, x_j) - \Phi_j^n, \quad j = 0, 1, \dots, M, \quad n \geq 0, \quad (2.33)$$

with Φ_j^n being the approximations obtained from the FDTD methods.

For the CNFD (2.9), we can establish the following error bound (see its proof in Appendix A).

Theorem 2.1. *Under the assumptions (A) and (B), there exist constants $h_0 > 0$ and $\tau_0 > 0$ sufficiently small and independent of ε , such that for any $0 < \varepsilon \leq 1$, $0 < h \leq h_0$ and $0 < \tau \leq \tau_0$, we have the following error estimate for the CNFD (2.9) with (2.10)*

$$\|\mathbf{e}^n\|_{l^2} \lesssim \frac{h^2}{\varepsilon} + \frac{\tau^2}{\varepsilon^6}, \quad 0 \leq n \leq \frac{T}{\tau}. \quad (2.34)$$

For the LFFD (2.6), we assume the stability condition

$$0 < \tau \leq \frac{\varepsilon^2 h}{\varepsilon^2 h V_{\max} + \sqrt{h^2 + \varepsilon^2(1 + \varepsilon h A_{1,\max})^2}}, \quad h > 0, \quad 0 < \varepsilon \leq 1, \quad (2.35)$$

and establish the following error estimate (see its proof in Appendix B).

Theorem 2.2. *Under the assumptions (A) and (B), there exist constants $h_0 > 0$ and $\tau_0 > 0$ sufficiently small and independent of ε , such that for any $0 < \varepsilon \leq 1$, when $0 < h \leq h_0$ and $0 < \tau \leq \tau_0$ and under the stability condition (2.35), we have the following error estimate for the LFFD (2.6) with (2.10) and (2.11)*

$$\|\mathbf{e}^n\|_{l^2} \lesssim \frac{h^2}{\varepsilon} + \frac{\tau^2}{\varepsilon^6}, \quad 0 \leq n \leq \frac{T}{\tau}. \quad (2.36)$$

Similarly to the proofs of the LFFD and CNFD methods, error estimates for SIFD1 (2.7) and SIFD2 (2.8) can be derived and the details are omitted here for brevity. For the SIFD2 (2.8), we assume the stability condition

$$0 < \tau \leq \frac{1}{V_{\max} + A_{1,\max}}, \quad h > 0, \quad 0 < \varepsilon \leq 1, \quad (2.37)$$

and establish the following error estimates.

Theorem 2.3. *Under the assumptions (A) and (B), there exist constants $h_0 > 0$ and $\tau_0 > 0$ sufficiently small and independent of ε , such that for any $0 < \varepsilon \leq 1$, when $0 < h \leq h_0$ and $0 < \tau \leq \tau_0$ and under the stability condition (2.15), we have the following error estimate for the SIFD1 (2.7) with (2.10) and (2.11)*

$$\|\mathbf{e}^n\|_{l^2} \lesssim \frac{h^2}{\varepsilon} + \frac{\tau^2}{\varepsilon^6}, \quad 0 \leq n \leq \frac{T}{\tau}. \quad (2.38)$$

Theorem 2.4. *Under the assumptions (A) and (B), there exist constants $h_0 > 0$ and $\tau_0 > 0$ sufficiently small and independent of ε , such that for any $0 < \varepsilon \leq 1$, when $0 < h \leq h_0$ and $0 < \tau \leq \tau_0$ and under the stability condition (2.37), we have the following error estimate for the SIFD2 (2.8) with (2.10) and (2.11)*

$$\|\mathbf{e}^n\|_{l^2} \lesssim \frac{h^2}{\varepsilon} + \frac{\tau^2}{\varepsilon^6}, \quad 0 \leq n \leq \frac{T}{\tau}. \quad (2.39)$$

Based on Theorems 2.1-2.4, the four FDTD methods studied here share the same temporal/spatial resolution capacity in the nonrelativistic limit regime. In fact, given an accuracy bound $\delta > 0$, the ε -scalability of the four FDTD methods is:

$$\tau = O\left(\varepsilon^3 \sqrt{\delta}\right) = O(\varepsilon^3), \quad h = O\left(\sqrt{\delta \varepsilon}\right) = O(\sqrt{\varepsilon}), \quad 0 < \varepsilon \ll 1. \quad (2.40)$$

3. An EWI-FP method and its analysis

In this section, we propose an exponential wave integrator Fourier pseudospectral (EWI-FP) method to solve the Dirac equation (1.9) (or (1.21)) and establish its stability and convergence in the nonrelativistic limit regime. Again, for simplicity of notations, we shall only present the numerical method and its analysis for (2.1) in 1D. Generalization to (1.9) and/or higher dimensions is straightforward and the results remain valid without modifications (see generalizations in Appendix D).

3.1. The EWI-FP method

Denote

$$Y_M = Z_M \times Z_M, \quad \text{with} \quad Z_M = \text{span} \left\{ \phi_l(x) = e^{i\mu_l(x-a)}, \quad l = -\frac{M}{2}, -\frac{M}{2} + 1, \dots, \frac{M}{2} - 1 \right\}.$$

Let $[C_p(\bar{\Omega})]^2$ be the function space consisting of all periodic vector function $U(x) : \bar{\Omega} = [a, b] \rightarrow \mathbb{C}^2$. For any $U(x) \in [C_p(\bar{\Omega})]^2$ and $U \in X_M$, define $P_M : [L^2(\Omega)]^2 \rightarrow Y_M$ as the standard projection operator [69], $I_M : [C_p(\bar{\Omega})]^2 \rightarrow Y_M$ and $I_M : X_M \rightarrow Y_M$ as the standard interpolation operator [69], i.e.

$$(P_M U)(x) = \sum_{l=-M/2}^{M/2-1} \hat{U}_l e^{i\mu_l(x-a)}, \quad (I_M U)(x) = \sum_{l=-M/2}^{M/2-1} \tilde{U}_l e^{i\mu_l(x-a)}, \quad a \leq x \leq b, \quad (3.1)$$

with

$$\hat{U}_l = \frac{1}{b-a} \int_a^b U(x) e^{-i\mu_l(x-a)} dx, \quad \tilde{U}_l = \frac{1}{M} \sum_{j=0}^{M-1} U_j e^{-2ijl\pi/M}, \quad l = -\frac{M}{2}, -\frac{M}{2} + 1, \dots, \frac{M}{2} - 1, \quad (3.2)$$

where $U_j = U(x_j)$ when U is a function.

The Fourier spectral discretization for the Dirac equation (2.1) is as follows:

Find $\Phi_M(t, x) \in Y_M$, i.e.

$$\Phi_M(t, x) = \sum_{l=-M/2}^{M/2-1} \widehat{(\Phi_M)}_l(t) e^{i\mu_l(x-a)}, \quad a \leq x \leq b, \quad t \geq 0, \quad (3.3)$$

such that for $a < x < b$ and $t > 0$,

$$i\partial_t \Phi_M(t, x) = \left[-\frac{i}{\varepsilon} \sigma_1 \partial_x + \frac{1}{\varepsilon^2} \sigma_3 \right] \Phi_M(t, x) + P_M(V\Phi_M)(t, x) - \sigma_1 P_M(A_1\Phi_M)(t, x). \quad (3.4)$$

Substituting (3.3) into (3.4), noticing the orthogonality of $\phi_l(x)$, we get for $l = -\frac{M}{2}, \dots, \frac{M}{2} - 1$,

$$i \frac{d}{dt} \widehat{(\Phi_M)}_l(t) = \left[\frac{\mu_l}{\varepsilon} \sigma_1 + \frac{1}{\varepsilon^2} \sigma_3 \right] \widehat{(\Phi_M)}_l(t) + \widehat{(V\Phi_M)}_l(t) - \sigma_1 \widehat{(A_1\Phi_M)}_l(t) = 0, \quad t \geq 0. \quad (3.5)$$

For each l ($l = -\frac{M}{2}, -\frac{M}{2} + 1, \dots, \frac{M}{2} - 1$), when t is near $t = t_n$ ($n \geq 0$), we rewrite the above ODEs as

$$i \frac{d}{ds} \widehat{(\Phi_M)}_l(t_n + s) = \frac{1}{\varepsilon^2} \Gamma_l \widehat{(\Phi_M)}_l(t_n + s) + \widehat{F}_l^n(s), \quad s \in \mathbb{R}, \quad (3.6)$$

where

$$\widehat{F}_l^n(s) = \widehat{(G\Phi_M)}_l(t_n + s), \quad G(t, x) = V(t, x)I_2 - \sigma_1 A_1(t, x), \quad s, t \in \mathbb{R}, \quad (3.7)$$

and $\Gamma_l = \mu_l \varepsilon \sigma_1 + \sigma_3 = Q_l D_l (Q_l)^*$ with

$$\Gamma_l = \begin{pmatrix} 1 & \mu_l \varepsilon \\ \mu_l \varepsilon & -1 \end{pmatrix}, \quad Q_l = \begin{pmatrix} \frac{1+\delta_l}{\sqrt{2\delta_l(1+\delta_l)}} & -\frac{\varepsilon\mu_l}{\sqrt{2\delta_l(1+\delta_l)}} \\ \frac{\varepsilon\mu_l}{\sqrt{2\delta_l(1+\delta_l)}} & \frac{1+\delta_l}{\sqrt{2\delta_l(1+\delta_l)}} \end{pmatrix}, \quad D_l = \begin{pmatrix} \delta_l & 0 \\ 0 & -\delta_l \end{pmatrix}, \quad \delta_l = \sqrt{1 + \varepsilon^2 \mu_l^2}. \quad (3.8)$$

Solving the above ODE (3.6) via the integrating factor method, we obtain

$$\widehat{(\Phi_M)}_l(t_n + s) = e^{-is\Gamma_l/\varepsilon^2} \widehat{(\Phi_M)}_l(t_n) - i \int_0^s e^{i(w-s)\Gamma_l/\varepsilon^2} \widehat{F}_l^n(w) dw, \quad s \in \mathbb{R}. \quad (3.9)$$

Taking $s = \tau$ in (3.9) we have

$$\widehat{(\Phi_M)}_l(t_{n+1}) = e^{-i\tau\Gamma_l/\varepsilon^2} \widehat{(\Phi_M)}_l(t_n) - i \int_0^\tau e^{\frac{i(w-\tau)\Gamma_l}{\varepsilon^2}} \widehat{F}_l^n(w) dw. \quad (3.10)$$

To obtain an explicit numerical method with second order accuracy in time, we approximate the integrals in (3.10) via the Gautschi-type rules [40, 48, 49], which have been widely used for integrating highly oscillatory ODEs [6, 12, 40, 48, 49, 53, 54], as

$$\int_0^\tau e^{\frac{i(w-\tau)\Gamma_l}{\varepsilon^2}} \widehat{F}_l^n(w) dw \approx \int_0^\tau e^{\frac{i(w-\tau)\Gamma_l}{\varepsilon^2}} dw \widehat{F}_l^n(0) = -i\varepsilon^2\Gamma_l^{-1} \left[I_2 - e^{-\frac{i\tau}{\varepsilon^2}\Gamma_l} \right] \widehat{F}_l^n(0), \quad (3.11)$$

and

$$\begin{aligned} \int_0^\tau e^{\frac{i(w-\tau)\Gamma_l}{\varepsilon^2}} \widehat{F}_l^n(w) dw &\approx \int_0^\tau e^{\frac{i(w-\tau)\Gamma_l}{\varepsilon^2}} \Gamma_l \left(\widehat{F}_l^n(0) + w\delta_t^- \widehat{F}_l^n(0) \right) dw \\ &= -i\varepsilon^2\Gamma_l^{-1} \left[I_2 - e^{-\frac{i\tau}{\varepsilon^2}\Gamma_l} \right] \widehat{F}_l^n(0) + \left[-i\varepsilon^2\tau\Gamma_l^{-1} + \varepsilon^4\Gamma_l^{-2} \left(I_2 - e^{-\frac{i\tau}{\varepsilon^2}\Gamma_l} \right) \right] \delta_t^- \widehat{F}_l^n(0), \quad n \geq 1, \end{aligned} \quad (3.12)$$

where we have approximated the time derivative $\partial_t \widehat{F}_l^n(s)$ at $s = 0$ for $n \geq 1$ by the finite difference as

$$\partial_t \widehat{F}_l^n(0) \approx \delta_t^- \widehat{F}_l^n(0) = \frac{\widehat{F}_l^n(0) - \widehat{F}_l^{n-1}(0)}{\tau}. \quad (3.13)$$

Now, we are ready to describe our scheme. Let $\Phi_M^n(x)$ be the approximation of $\Phi_M(t_n, x)$ ($n \geq 0$). Choosing $\Phi_M^0(x) = (P_M \Phi_0)(x)$, an *exponential wave integrator Fourier spectral* (EWI-FS) discretization for the Dirac equation (2.1) is to update the numerical approximation $\Phi_M^{n+1}(x) \in Y_M$ ($n = 0, 1, \dots$) as

$$\Phi_M^{n+1}(x) = \sum_{l=-M/2}^{M/2-1} \widehat{(\Phi_M^{n+1})}_l e^{i\mu_l(x-a)}, \quad a \leq x \leq b, \quad n \geq 0, \quad (3.14)$$

where for $l = -\frac{M}{2}, \dots, \frac{M}{2} - 1$,

$$\widehat{(\Phi_M^{n+1})}_l = \begin{cases} e^{-i\tau\Gamma_l/\varepsilon^2} \widehat{(\Phi_M^0)}_l - i\varepsilon^2\Gamma_l^{-1} \left[I_2 - e^{-\frac{i\tau}{\varepsilon^2}\Gamma_l} \right] (G(t_0) \widehat{\Phi_M^0})_l, & n = 0, \\ e^{-i\tau\Gamma_l/\varepsilon^2} \widehat{(\Phi_M^n)}_l - iQ_l^{(1)}(\tau) (G(t_n) \widehat{\Phi_M^n})_l - iQ_l^{(2)}(\tau) \delta_t^- (G(t_n) \widehat{\Phi_M^n})_l, & n \geq 1, \end{cases} \quad (3.15)$$

with $G(t)$ denoting $G(t, x)$ and the matrices $Q_l^{(1)}(\tau)$ and $Q_l^{(2)}(\tau)$ given as

$$Q_l^{(1)}(\tau) = -i\varepsilon^2\Gamma_l^{-1} \left[I_2 - e^{-\frac{i\tau}{\varepsilon^2}\Gamma_l} \right], \quad Q_l^{(2)}(\tau) = -i\varepsilon^2\tau\Gamma_l^{-1} + \varepsilon^4\Gamma_l^{-2} \left(I_2 - e^{-\frac{i\tau}{\varepsilon^2}\Gamma_l} \right). \quad (3.16)$$

The above procedure is not suitable in practice due to the difficulty in computing the Fourier coefficients through integrals in (3.2). Here we present an efficient implementation by choosing $\Phi_M^0(x)$ as the interpolant of $\Phi_0(x)$ on the grids $\{x_j, j = 0, 1, \dots, M\}$ and approximate the integrals in (3.2) by a quadrature rule.

Let Φ_j^n be the numerical approximation of $\Phi(t_n, x_j)$ for $j = 0, 1, 2, \dots, M$ and $n \geq 0$, and denote $\Phi^n \in X_M$ as the vector with components Φ_j^n . Choosing $\Phi_j^0 = \Phi_0(x_j)$ ($j = 0, 1, \dots, M$), an *EWI Fourier pseudospectral* (EWI-FP) method for computing Φ^{n+1} for $n \geq 0$ reads

$$\Phi_j^{n+1} = \sum_{l=-M/2}^{M/2-1} \widehat{(\Phi^{n+1})}_l e^{2ijl\pi/M}, \quad j = 0, 1, \dots, M, \quad (3.17)$$

where

$$\widetilde{(\Phi^{n+1})}_l = \begin{cases} e^{-i\tau\Gamma_l/\varepsilon^2} \widetilde{(\Phi^0)}_l - i\varepsilon^2\Gamma_l^{-1} \left[I_2 - e^{-\frac{i\tau}{\varepsilon^2}\Gamma_l} \right] (G(t_0)\widetilde{(\Phi^0)})_l, & n = 0, \\ e^{-i\tau\Gamma_l/\varepsilon^2} \widetilde{(\Phi^n)}_l - iQ_l^{(1)}(\tau)(G(t_n)\widetilde{(\Phi^n)})_l - iQ_l^{(2)}(\tau)\delta_t^-(G(t_n)\widetilde{(\Phi^n)})_l, & n \geq 1. \end{cases} \quad (3.18)$$

The EWI-FP (3.17)-(3.18) is explicit, and can be computed efficiently by the fast Fourier transform (FFT). The memory cost is $O(M)$ and the computational cost per time step is $O(M \log M)$.

3.2. Linear stability analysis

To consider the linear stability, we assume that in the Dirac equation (2.1), the external potential fields are constants, i.e. $A_1(t, x) \equiv A_1^0$ and $V(t, x) \equiv V^0$ with A_1^0 and V^0 being two real constants. In this case, we adopt the Von Neumann stability requirement that the errors grow exponentially at most. Then we have

Lemma 3. *The EWI-FP method (3.17)-(3.18) and EWI-FS method (3.14)-(3.15) are stable under the stability condition*

$$0 < \tau \lesssim 1, \quad 0 < \varepsilon \leq 1. \quad (3.19)$$

Proof: We shall only prove the EWI-FS case (3.14)-(3.15), as the EWI-FP method case (3.18) is quite the same. Similarly to the proof of Lemma 1, noticing (3.15), (3.7), (3.10) and (3.12), we find that

$$\xi_l^2 \widetilde{(\Phi^0)}_l = \xi_l e^{-i\tau\Gamma_l/\varepsilon^2} \widetilde{(\Phi^0)}_l - i \int_0^\tau e^{i(w-\tau)\Gamma_l/\varepsilon^2} (V^0 I_2 - A_1^0 \sigma_1) \left(\xi_l + \frac{w}{\tau} (\xi_l - 1) \right) \widetilde{(\Phi^0)}_l dw. \quad (3.20)$$

Denoting $C = |V^0| + |A_1^0|$, taking the l^2 norms of the vectors on both sides of (3.20) and then dividing both sides by the l^2 norm of $\widetilde{(\Phi^0)}_l$, in view of the properties of $e^{-is\Gamma_l/\varepsilon^2}$, we get

$$|\xi_l|^2 \leq \left(1 + C\tau + \frac{C}{2}\tau \right) |\xi_l| + \frac{C}{2}\tau, \quad (3.21)$$

which implies

$$\left(|\xi_l| - \frac{1 + 3C\tau/2}{2} \right)^2 \leq \frac{1 + 5C\tau + 9C^2\tau^2/4}{4} \leq \frac{(1 + 5C\tau/2)^2}{4}. \quad (3.22)$$

Thus, we obtain

$$|\xi_l| \leq 1 + 4C\tau, \quad l = -\frac{M}{2}, \dots, \frac{M}{2} - 1, \quad (3.23)$$

and it follows that the EWI-FS (3.14)-(3.15) is stable under the stability condition (3.19). \square

3.3. Error estimates

In order to obtain an error estimate for the EWI methods (3.14)-(3.15) and (3.17)-(3.18), motivated by the results in [19, 24], we assume that there exists an integer $m_0 \geq 2$ such that the exact solution $\Phi(t, x)$ of the Dirac equation (2.1) satisfies

$$(C) \quad \|\Phi\|_{L^\infty([0,T];(H_p^{m_0})^2)} \lesssim 1, \quad \|\partial_t \Phi\|_{L^\infty([0,T];(L^2)^2)} \lesssim \frac{1}{\varepsilon^2}, \quad \|\partial_{tt} \Phi\|_{L^\infty([0,T];(L^2)^2)} \lesssim \frac{1}{\varepsilon^4},$$

where $H_p^k(\Omega) = \{u \mid u \in H^k(\Omega), \partial_x^l u(a) = \partial_x^l u(b), l = 0, \dots, k-1\}$. In addition, we assume the electromagnetic potentials satisfy

$$(D) \quad \|V\|_{W^{2,\infty}([0,T];L^\infty)} + \|A_1\|_{W^{2,\infty}([0,T];L^\infty)} \lesssim 1.$$

The following estimate can be established (see its proof in Appendix C).

Theorem 3.1. *Let $\Phi_M^n(x)$ be the approximation obtained from the EWI-FS (3.14)-(3.15). Under the assumptions (C) and (D), there exists $h_0 > 0$ and $\tau_0 > 0$ sufficiently small and independent of ε such that, for any $0 < \varepsilon \leq 1$, when $0 < h \leq h_0$ and $0 < \tau \leq \tau_0$ satisfying the stability condition (2.37), we have the following error estimate*

$$\|\Phi(t_n, x) - \Phi_M^n(x)\|_{L^2} \lesssim \frac{\tau^2}{\varepsilon^4} + h^{m_0}, \quad 0 \leq n \leq \frac{T}{\tau}. \quad (3.24)$$

Remark 3.1. *The same error estimate in Theorem 3.1 holds for the EWI-FP (3.17)-(3.18) and the proof is quite similar to that of Theorem 3.1.*

4. A TSFP method and its analysis

In this section, we present a time-splitting Fourier pseudospectral (TSFP) method to solve the Dirac equation(1.9) (or (1.21)) which has been proposed and studied for the Maxwell-Dirac equation [17, 51]. Again, for simplicity of notations, we shall only present the numerical method and its analysis for (2.1) in 1D. Generalization to (1.9) and/or higher dimensions is straightforward and results remain valid without modifications (see generalizations in Appendix D).

From time $t = t_n$ to time $t = t_{n+1}$, the Dirac equation (2.1) is split into two steps. One solves first

$$i\partial_t \Phi(t, x) = \left[-\frac{i}{\varepsilon} \sigma_1 \partial_x + \frac{1}{\varepsilon^2} \sigma_3 \right] \Phi(t, x), \quad x \in \Omega, \quad (4.1)$$

with the periodic boundary condition (2.2) for the time step of length τ , followed by solving

$$i\partial_t \Phi(t, x) = [-A_1(t, x) \sigma_1 + V(t, x) I_2] \Phi(t, x), \quad x \in \Omega, \quad (4.2)$$

for the same time step. Eq. (4.1) will be first discretized in space by the Fourier spectral method and then integrated (in phase or Fourier space) in time exactly [17]. For the ODEs (4.2), we can integrate *analytically* in time as

$$\Phi(t, x) = e^{-i \int_{t_n}^t [V(s, x) I_2 - A_1(s, x) \sigma_1] ds} \Phi(t_n, x), \quad a \leq x \leq b, \quad t_n \leq t \leq t_{n+1}. \quad (4.3)$$

In practical computation, from time $t = t_n$ to $t = t_{n+1}$, one often combines the splitting steps via the standard Strang splitting [72] – which results in a second order time-splitting Fourier pseudospectral (TSFP) method – as

$$\begin{aligned} \Phi_j^{(1)} &= \sum_{l=-M/2}^{M/2-1} e^{-i\tau \Gamma_l / 2\varepsilon^2} (\widetilde{\Phi^n})_l e^{i\mu_l(x_j - a)} = \sum_{l=-M/2}^{M/2-1} Q_l e^{-i\tau D_l / 2\varepsilon^2} (Q_l)^* (\widetilde{\Phi^n})_l e^{\frac{2ijl\pi}{M}}, \\ \Phi_j^{(2)} &= e^{-i \int_{t_n}^{t_{n+1}} G(t, x_j) dt} \Phi_j^{(1)} = P_j e^{-i\Lambda_j} P_j^* \Phi_j^{(1)}, \quad j = 0, 1, \dots, M, \quad n \geq 0, \\ \Phi_j^{n+1} &= \sum_{l=-M/2}^{M/2-1} e^{-i\tau \Gamma_l / 2\varepsilon^2} (\widetilde{\Phi^{(2)}})_l e^{i\mu_l(x_j - a)} = \sum_{l=-M/2}^{M/2-1} Q_l e^{-i\tau D_l / 2\varepsilon^2} (Q_l)^* (\widetilde{\Phi^{(2)}})_l e^{\frac{2ijl\pi}{M}}, \end{aligned} \quad (4.4)$$

where $\int_{t_n}^{t_{n+1}} G(t, x_j) dt = V_j^{(1)} I_2 - A_{1,j}^{(1)} \sigma_1 = P_j \Lambda_j P_j^*$ with $V_j^{(1)} = \int_{t_n}^{t_{n+1}} V(t, x_j) dt$, $A_{1,j}^{(1)} = \int_{t_n}^{t_{n+1}} A_1(t, x_j) dt$, $\Lambda_j = \text{diag}(\Lambda_{j,-}, \Lambda_{j,+})$ with $\Lambda_{j,\pm} = V_j^{(1)} \pm A_{1,j}^{(1)}$, and $P_j = I_2$ if $A_{1,j}^{(1)} = 0$ and otherwise

$$P_j = P^{(0)} := \begin{pmatrix} \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \\ -\frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \end{pmatrix}. \quad (4.5)$$

Remark 4.1. *Again, if the definite integrals in $\int_{t_n}^{t_{n+1}} \Lambda(t, x_j) dt$ cannot be evaluated analytically, we can evaluate them numerically via the Simpson's quadrature rule as*

$$\begin{aligned} \int_{t_n}^{t_{n+1}} A_1(t, x_j) dt &\approx \frac{\tau}{6} \left[A_1(t_n, x_j) + 4A_1\left(t_n + \frac{\tau}{2}, x_j\right) + A_1(t_{n+1}, x_j) \right], \\ \int_{t_n}^{t_{n+1}} V(t, x_j) dt &\approx \frac{\tau}{6} \left[V(t_n, x_j) + 4V\left(t_n + \frac{\tau}{2}, x_j\right) + V(t_{n+1}, x_j) \right]. \end{aligned}$$

Table 5.1: Spatial and temporal error analysis of the LFFD method for the Dirac equation (1.21) in 1D.

Lemma 4. *The TSFP (4.4) conserves the mass in the discretized level, i.e.*

$$\|\Phi^n\|_{l^2}^2 := h \sum_{j=0}^{M-1} |\Phi_j^n|^2 \equiv h \sum_{j=0}^{M-1} |\Phi_j^0|^2 = \|\Phi^0\|_{l^2}^2 = h \sum_{j=0}^{M-1} |\Phi_0(x_j)|^2, \quad n \geq 0. \quad (4.6)$$

Proof: The proof is quite standard and similar to that of Lemma 2. We omit it here. \square

From Lemma 4, we conclude that the TSFP (4.4) is unconditionally stable. In addition, under proper assumptions of the exact solution $\Phi(t, x)$ and electromagnetic potentials, it is easy to show the following error estimate via the formal Lie calculus introduced in [56],

$$\|\Phi(t_n, x) - I_M(\Phi^n)\|_{L^2} \lesssim h^{m_0} + \frac{\tau^2}{\varepsilon^4}, \quad 0 \leq n \leq \frac{T}{\tau}, \quad (4.7)$$

where m_0 depends on the regularity of $\Phi(t, x)$. We omit the details here for brevity.

5. Numerical comparison and applications

In this section, we compare the accuracy of different numerical methods including the FDTD, EWI-FP and TSFP methods for the Dirac equation (1.21) in 1D in terms of the mesh size h , time step τ and the parameter $0 < \varepsilon \leq 1$. We will pay particular attention to the ε -scalability of different methods in the nonrelativistic limit regime, i.e. $0 < \varepsilon \ll 1$. Then we simulate the dynamics of the Dirac equation (1.21) in 2D with a honeycomb lattice potential by the TSFP method.

5.1. Comparison of spatial/temporal resolution

To test the accuracy, we choose the electromagnetic potentials in the Dirac equation (1.21) with $d = 1$ as

$$A_1(t, x) = \frac{(x+1)^2}{1+x^2}, \quad V(t, x) = \frac{1-x}{1+x^2}, \quad x \in \mathbb{R}, \quad t \geq 0, \quad (5.8)$$

and the initial data as

$$\phi_1(0, x) = e^{-x^2/2}, \quad \phi_2(0, x) = e^{-(x-1)^2/2}, \quad x \in \mathbb{R}. \quad (5.9)$$

The problem is solved numerically on an interval $\Omega = (-16, 16)$ with periodic boundary conditions on $\partial\Omega$. The ‘reference’ solution $\Phi(t, x) = (\phi_1(t, x), \phi_2(t, x))^T$ is obtained numerically by using the TSFP method with a small time step and a very fine mesh size, e.g. $\tau_e = 10^{-7}$ and $h_e = 1/16$ or $h_e = 1/4096$ for the comparison of the EWI-FP/TSFP methods or the FDTD methods, respectively. Denote $\Phi_{h,\tau}^n$ as the numerical solution obtained by a numerical method with mesh size h and time step τ . In order to quantify the convergence, we introduce

$$e_{h,\tau}(t_n) = \|\Phi^n - \Phi(t_n, \cdot)\|_{l^2} = \sqrt{h \sum_{j=0}^{M-1} |\Phi_j^n - \Phi(t_n, x_j)|^2}.$$

Table 5.1 lists spatial errors $e_{h,\tau_e}(t = 2)$ with different h (upper part) and temporal errors $e_{h_e,\tau}(t = 2)$ with different τ (lower part) for the LFFD method (2.6). Tables 5.2-5.6 show similar results for the SIFD1 method (2.7), SIFD2 method (2.8), CNFD method (2.9), EWI-FP method (3.17)-(3.18) and TSFP method (4.4), respectively. For the LFFD and SIFD1 methods, due to the stability condition and accuracy requirement, we take

$$\delta_j(\varepsilon) = \begin{cases} \varepsilon^2 & \varepsilon_0/2^j \leq \varepsilon \leq 1, \\ \varepsilon_0^2/4^j & 0 < \varepsilon < \varepsilon_0/2^j, \end{cases} \quad j = 0, 1, \dots$$

in Tables 5.1 and 5.2. For comparison, Table 5.7 depicts temporal errors of different numerical methods when $\varepsilon = 1$ for different τ , Table 5.8 depicts temporal errors of different numerical methods under different ε -scalability.

From Tables 5.1-5.8, and additional numerical results not shown here for brevity, we can draw the following conclusions for the Dirac equation by using different numerical methods:

(i). For the discretization error in space, for any fixed $\varepsilon = \varepsilon_0 > 0$, the FDTD methods are second-order accurate, and resp., the EWI-FP and TSFP methods are spectrally accurate (cf. each row in the upper parts of Tables 5.1-5.6 and Table 5.7). For $0 < \varepsilon \leq 1$, the errors are independent of ε for the EWI-FP and TSFP methods (cf. each column in the upper parts of Tables 5.5-5.6), and resp., are almost independent of ε for the FDTD methods (cf. each column in the upper parts of Tables 5.1-5.4). In general, for any fixed $0 < \varepsilon \leq 1$ and $h > 0$, the EWI-FP and TSFP methods perform much better than the FDTD methods in spatial discretization.

(ii). For the discretization error in time, in the $O(1)$ speed-of-light regime, i.e. $\varepsilon = O(1)$, all the numerical methods including FDTD, EWI-FP and TSFP are second-order accurate (cf. the first row in the lower parts of Tables 5.1-5.6). In general, the EWI-FP and TSFP methods perform much better than the FDTD methods in temporal discretizations for a fixed time step. In the non-relativistic limit regime, i.e. $0 < \varepsilon \ll 1$, for the FDTD methods, the ‘correct’ ε -scalability is $\tau = O(\varepsilon^3)$ which verifies our theoretical results; for the EWI-FP and TSFP methods, the ‘correct’ ε -scalability is $\tau = O(\varepsilon^2)$ which again confirms our theoretical results. In fact, for $0 < \varepsilon \leq 1$, one can observe clearly second-order convergence in time for the FDTD methods only when $\tau \lesssim \varepsilon^3$ (cf. upper triangles in the lower parts of Tables 5.1-5.4), and resp., for the EWI-FP and TSFP methods when $\tau \lesssim \varepsilon^2$ (cf. upper triangles in the lower parts of Tables 5.5-5.6). In general, for any fixed $0 < \varepsilon \leq 1$ and $\tau > 0$, the TSFP method performs the best, and the EWI-FP method performs much better than the FDTD methods in temporal discretization (cf. Table 5.8).

Table 5.2: Spatial and temporal error analysis of the SIFD1 method for the Dirac equation (1.21) in 1D.

| $\varepsilon_0/2^4$ | unstable | unstable | 4.19E-1 | 7.97E-1 | 1.26E-2 |
| order | – | – | – | -0.31 | 1.99 |

(iii). From Table 5.6, our numerical results suggest the following error bound for the TSFP method when $\tau \lesssim \varepsilon^2$,

$$\|\Phi(t_n, \cdot) - I_M(\Phi^n)\|_{L^2} \lesssim h^{m_0} + \frac{\tau^2}{\varepsilon^2}, \quad 0 \leq n \leq \frac{T}{\tau}, \quad (5.10)$$

which is much better than (4.7) for the TSFP method in the nonrelativistic limit regime. Rigorous mathematical justification for (5.10) is on-going.

From Tables 5.1-5.4, in the numerical example, we could not observe numerically the ε -dependence in the spatial discretization error for the FDTD methods, i.e. $\frac{1}{\varepsilon}$ in front of h^2 , which was proven in Theorems 2.1-2.4. In order to investigate the spatial ε -resolution of the FDTD methods, we consider the Dirac equation (2.1) on $\Omega = (-1, 1)$ with no electromagnetic potential – the free Dirac equation, i.e.

$$A_1(t, x) \equiv 0, \quad V(t, x) \equiv 0, \quad x \in (-1, 1), \quad t \geq 0. \quad (5.11)$$

The initial data in (2.2) is taken as

$$\phi_1(0, x) = e^{9\pi i(x+1)}, \quad \phi_2(0, x) = e^{9\pi i(x+1)}, \quad -1 \leq x \leq 1. \quad (5.12)$$

Table 5.9 shows the spatial errors $e_{h, \tau_\varepsilon}(t = 2)$ of the CNFD method with different h . The results for the LFFD, SIFD1 and SIFD2 methods are similar and they are omitted here for brevity. From Table 5.9, we can conclude that the error bounds in the Theorems 2.1-2.4 are sharp.

Based on the above comparison, in view of both temporal and spatial accuracies and resolution capacity, we conclude that the EWI-FP and TSFP methods perform much better than the FDTD methods for the discretization of the Dirac equation, especially in the nonrelativistic limit regime. For the reader's convenience, we summarize the properties of different numerical methods in Table 5.10.

As observed in [15, 16], the time-splitting spectral (TSSP) method for the Schrödinger equation performs much better for the physical observable, e.g. density and current, than for the wave function, in the semiclassical limit regime with respect to the scaled Planck constant $0 < \varepsilon \ll 1$. In order to see whether this is still valid for the TSFP method for the Dirac equation in the nonrelativistic limit regime, let $\rho^n = |\Phi_{h,\tau}^n|^2$, $\mathbf{J}^n = \frac{1}{\varepsilon}(\Phi_{h,\tau}^n)^* \sigma_1 \Phi_{h,\tau}^n$ with $\Phi_{h,\tau}^n$ the numerical solution obtained by the TSFP method with mesh size h and time step τ , and define the errors

$$e_\rho^{h,\tau}(t_n) := \|\rho^n - \rho(t_n, \cdot)\|_{l^1} = h \sum_{j=0}^{N-1} |\rho_j^n - \rho(t_n, x_j)|, \quad e_{\mathbf{J}}^{h,\tau}(t_n) := \|\mathbf{J}^n - \mathbf{J}(t_n, \cdot)\|_{l^1} = h \sum_{j=0}^{N-1} |\mathbf{J}_j^n - \mathbf{J}(t_n, x_j)|.$$

Table 5.11 lists temporal errors $e_\rho^{h,\tau}(t=2)$ and $e_{\mathbf{J}}^{h,\tau}(t=2)$ with different τ for the TSFP method (4.4). From this Table, we can see that the approximations of the density and current are at the same order as for the wave function by using the TSFP method. The reason that we can speculate is that $\rho = O(1)$ and $\mathbf{J} = O(\varepsilon^{-1})$ (see details in (1.11) or (1.23)) in the Dirac equation, where in the Schrödinger equation both density and current are all at $O(1)$, when $0 < \varepsilon \ll 1$.

5.2. Dynamics of the Dirac equation in 2D

Here we study numerically the dynamics of the Dirac equation (1.21) in 2D with a honeycomb lattice potential, i.e. we take $d = 2$ and

$$A_1(t, \mathbf{x}) = A_2(t, \mathbf{x}) \equiv 0, \quad V(t, \mathbf{x}) = \cos\left(\frac{4\pi}{\sqrt{3}}\mathbf{e}_1 \cdot \mathbf{x}\right) + \cos\left(\frac{4\pi}{\sqrt{3}}\mathbf{e}_2 \cdot \mathbf{x}\right) + \cos\left(\frac{4\pi}{\sqrt{3}}\mathbf{e}_3 \cdot \mathbf{x}\right), \quad (5.13)$$

with

$$\mathbf{e}_1 = (-1, 0)^T, \quad \mathbf{e}_2 = (1/2, \sqrt{3}/2)^T, \quad \mathbf{e}_3 = (1/2, -\sqrt{3}/2)^T. \quad (5.14)$$

Table 5.6: Spatial and temporal error analysis of the TSFP method for the Dirac equation (1.21) in 1D.

The problem is solved numerically on $\Omega = [-10, 10]^2$ by the TSFP method with mesh size $h = 1/16$ and time step $\tau = 0.01$. Figures 5.1 and 5.2 depict the densities $\rho_j(t, \mathbf{x}) = |\phi_j(t, \mathbf{x})|^2$ ($j = 1, 2$) for $\varepsilon = 1$ and $\varepsilon = 0.2$, respectively.

From Figures 5.1-5.2, we find that the dynamics of the Dirac equation depends significantly on ε . In addition, the TSFP method can capture the dynamics very accurately and efficiently.

6. Conclusion

Three types of numerical methods based on different time integrations were analyzed rigorously and compared numerically for simulating the Dirac equation in the nonrelativistic limit regime, i.e. $0 < \varepsilon \ll 1$

Figure 5.1: Dynamics of the densities $\rho_1(t, \mathbf{x}) = |\phi_1(t, \mathbf{x})|^2$ (left) and $\rho_2(t, \mathbf{x}) = |\phi_2(t, \mathbf{x})|^2$ (right) of the Dirac equation in 2D with a honeycomb lattice potential when $\varepsilon = 1$.

Figure 5.2: Dynamics of the densities $\rho_1(t, \mathbf{x}) = |\phi_1(t, \mathbf{x})|^2$ (left) and $\rho_2(t, \mathbf{x}) = |\phi_2(t, \mathbf{x})|^2$ (right) of the Dirac equation in 2D with a honeycomb potential when $\varepsilon = 0.2$.

or the speed of light goes to infinity. The first class consists of the second order standard FDTD methods, including energy conservative/ nonconservative and implicit/semi-implicit/explicit ones. In the nonrelativistic limit regime, the error estimates of the FDTD methods were rigorously analyzed, which suggest that the ε -scalability of the FDTD methods is $\tau = O(\varepsilon^3)$ and $h = O(\sqrt{\varepsilon})$. The second class applies the Fourier spectral discretization in space and Gautschi-type integration in time, resulting in an EWI-FP method. Rigorous error bounds for the EWI-FP method were derived, which show that the ε -scalability of the EWI-FP method is $\tau = O(\varepsilon^2)$ and $h = O(1)$. The last class combines the Fourier spectral discretization in space and splitting technique in time, which leads to a TSFP method. Based on the rigorous error analysis, the ε -scalability of the TSFP method is $\tau = O(\varepsilon^2)$ and $h = O(1)$, which is similar to the EWI-FP method. From the error analysis and numerical results, the EWI-FP and TSFP methods perform much better than the FDTD methods, especially in the nonrelativistic limit regime. Extensive numerical results indicate that the TSFP method is superior than the EWI-FP in terms of accuracy and efficiency, and thus the TSFP method is favorable for solving the Dirac equation directly, especially in the nonrelativistic limit regime. Finally, we studied the dynamics of the Dirac equation in 2D with a honeycomb lattice potential and observed some interesting dynamics for different ε .

Appendix A. Proof of Theorem 2.1 for the CNFD method

Define the local truncation error $\xi^n = (\xi_0^n, \xi_1^n, \dots, \xi_M^n)^T \in X_M$ of the CNFD (2.9) with (2.10) as

$$\begin{aligned} \xi_j^n := & i\delta_t^+ \Phi(t_n, x_j) + \frac{i}{\varepsilon} \sigma_1 \frac{\delta_x \Phi(t_{n+1}, x_j) + \delta_x \Phi(t_n, x_j)}{2} - \frac{1}{\varepsilon^2} \sigma_3 \frac{\Phi(t_{n+1}, x_j) + \Phi(t_n, x_j)}{2} \\ & + [A_1(t_{n+1/2}, x_j) \sigma_1 - V(t_{n+1/2}, x_j) I_2] \frac{\Phi(t_{n+1}, x_j) + \Phi(t_n, x_j)}{2}, \quad 0 \leq j \leq M-1, \quad n \geq 0. \end{aligned} \quad (\text{A.1})$$

Applying the Taylor expansion in (A.1), noticing (2.1) and the assumptions (A) and (B), and using the triangle inequality, for $0 < \varepsilon \leq 1$, we obtain

$$\begin{aligned} |\xi_j^n| & \leq \frac{\tau^2}{24} \|\partial_{ttt} \Phi\|_{L^\infty(\bar{\Omega}_T)} + \frac{h^2}{6\varepsilon} \|\partial_{xxx} \Phi\|_{L^\infty(\bar{\Omega}_T)} + \frac{\tau^2}{8\varepsilon} \|\partial_{xtt} \Phi\|_{L^\infty(\bar{\Omega}_T)} + \frac{\tau^2}{8} \left(\frac{1}{\varepsilon^2} + V_{\max} + A_{1,\max} \right) \|\partial_{tt} \Phi\|_{L^\infty(\bar{\Omega}_T)} \\ & \lesssim \frac{\tau^2}{\varepsilon^6} + \frac{h^2}{\varepsilon} + \frac{\tau^2}{\varepsilon^5} + \frac{\tau^2}{\varepsilon^4} \lesssim \frac{\tau^2}{\varepsilon^6} + \frac{h^2}{\varepsilon}, \quad j = 0, 1, \dots, M-1, \quad n \geq 0, \end{aligned} \quad (\text{A.2})$$

which immediately implies

$$\|\xi^n\|_{l^\infty} = \max_{0 \leq j \leq M-1} |\xi_j^n| \lesssim \frac{\tau^2}{\varepsilon^6} + \frac{h^2}{\varepsilon}, \quad \|\xi^n\|_{l^2} \lesssim \|\xi^n\|_{l^\infty} \lesssim \frac{\tau^2}{\varepsilon^6} + \frac{h^2}{\varepsilon}, \quad n \geq 0, \quad 0 < \varepsilon \leq 1. \quad (\text{A.3})$$

Subtracting (2.9) from (A.1), noticing (2.33), we get for $n \geq 0$

$$i\delta_t^+ \mathbf{e}_j^n = -\frac{i}{\varepsilon} \sigma_1 \delta_x \mathbf{e}_j^{n+1/2} + \frac{1}{\varepsilon^2} \sigma_3 \mathbf{e}_j^{n+1/2} + \left(V_j^{n+1/2} I_2 - A_{1,j}^{n+1/2} \sigma_1 \right) \mathbf{e}_j^{n+1/2} + \xi_j^n, \quad 0 \leq j \leq M-1, \quad (\text{A.4})$$

with $\mathbf{e}_j^{n+1/2} = \frac{\mathbf{e}_j^{n+1} + \mathbf{e}_j^n}{2}$ for $j = 0, 1, \dots, M$, and the boundary and initial conditions are given as

$$\mathbf{e}_0^n = \mathbf{e}_M^n, \quad \mathbf{e}_{-1}^n = \mathbf{e}_{M-1}^n, \quad n \geq 0, \quad \mathbf{e}_j^0 = \mathbf{0}, \quad j = 0, 1, \dots, M. \quad (\text{A.5})$$

Similarly to the proof for Lemma 2, multiplying (A.4) from the left by $h\tau \left(\mathbf{e}_j^{n+1/2} \right)^*$, taking the imaginary part, then summing for $j = 0, 1, \dots, M-1$, using the triangle inequality and Young's inequality, noticing (1.3), (A.3) and (A.5), we get

$$\begin{aligned} \|\mathbf{e}^{n+1}\|_{l^2}^2 - \|\mathbf{e}^n\|_{l^2}^2 & \lesssim \tau h \sum_{j=0}^{M-1} |\xi_j^n| (|\mathbf{e}_j^{n+1}| + |\mathbf{e}_j^n|) \lesssim \tau (\|\xi^n\|_{l^2}^2 + \|\mathbf{e}^{n+1}\|_{l^2}^2 + \|\mathbf{e}^n\|_{l^2}^2) \\ & \lesssim \tau (\|\mathbf{e}^{n+1}\|_{l^2}^2 + \|\mathbf{e}^n\|_{l^2}^2) + \tau \left(\frac{h^2}{\varepsilon} + \frac{\tau^2}{\varepsilon^6} \right)^2, \quad n \geq 0. \end{aligned} \quad (\text{A.6})$$

Summing the above inequality for $n = 0, 1, \dots, m-1$, we get

$$\|\mathbf{e}^m\|_{l^2}^2 - \|\mathbf{e}^0\|_{l^2}^2 \lesssim \tau \sum_{k=0}^m \|\mathbf{e}^k\|_{l^2}^2 + \tau m \left(\frac{h^2}{\varepsilon} + \frac{\tau^2}{\varepsilon^6} \right)^2, \quad 0 \leq m \leq \frac{T}{\tau}. \quad (\text{A.7})$$

Taking τ_0 sufficiently small, when $0 < \tau \leq \tau_0$, we have

$$\|\mathbf{e}^m\|_{l^2}^2 \lesssim \tau \sum_{k=0}^{m-1} \|\mathbf{e}^k\|_{l^2}^2 + \tau m \left(\frac{h^2}{\varepsilon} + \frac{\tau^2}{\varepsilon^6} \right)^2 \leq \tau \sum_{k=0}^{m-1} \|\mathbf{e}^k\|_{l^2}^2 + T \left(\frac{h^2}{\varepsilon} + \frac{\tau^2}{\varepsilon^6} \right)^2, \quad 0 \leq m \leq \frac{T}{\tau}. \quad (\text{A.8})$$

Using the discrete Gronwall's inequality and noticing $\|\mathbf{e}^0\|_{l^2} = 0$, we obtain

$$\|\mathbf{e}^m\|_{l^2}^2 \lesssim T \left(\frac{h^2}{\varepsilon} + \frac{\tau^2}{\varepsilon^6} \right)^2 \lesssim \left(\frac{h^2}{\varepsilon} + \frac{\tau^2}{\varepsilon^6} \right)^2, \quad 0 \leq m \leq \frac{T}{\tau}, \quad (\text{A.9})$$

which immediately implies the error bound (2.34). \square

Appendix B. Proof of Theorem 2.2 for the LFFD method

Define the local truncation error $\tilde{\xi}^n = (\tilde{\xi}_0^n, \tilde{\xi}_1^n, \dots, \tilde{\xi}_M^n)^T \in X_M$ of the LFFD (2.6) with (2.10) and (2.11) as follows, for $0 \leq j \leq M-1$,

$$\tilde{\xi}_j^n := i\delta_t \Phi(t_n, x_j) + \frac{i}{\varepsilon} \sigma_1 \delta_x \Phi(t_n, x_j) - \frac{1}{\varepsilon^2} \sigma_3 \Phi(t_n, x_j) + [A_{1,j}^n \sigma_1 - V_j^n I_2] \Phi(t_n, x_j), \quad n \geq 1, \quad (\text{B.1})$$

$$\tilde{\xi}_j^0 := i\delta_t^+ \Phi(0, x_j) + \frac{i}{\varepsilon} \sigma_1 \delta_x \Phi_0(x_j) - \left(\frac{1}{\varepsilon^2} \sigma_3 + V_j^0 I_2 - A_{1,j}^0 \sigma_1 \right) \Phi_0(x_j). \quad (\text{B.2})$$

Applying the Taylor expansion in (B.1) and (B.2), noticing (2.1) and the assumptions (A) and (B), similarly to the proof of Theorem 2.1, we obtain

$$|\tilde{\xi}_j^0| \lesssim \frac{\tau}{\varepsilon^4} + \frac{h^2}{\varepsilon}, \quad |\tilde{\xi}_j^n| \lesssim \frac{\tau^2}{\varepsilon^6} + \frac{h^2}{\varepsilon}, \quad j = 0, 1, \dots, M-1, \quad n \geq 1, \quad (\text{B.3})$$

which immediately implies

$$\|\tilde{\xi}^n\|_{l^\infty} = \max_{0 \leq j \leq M-1} |\tilde{\xi}_j^n| \lesssim \frac{\tau^2}{\varepsilon^6} + \frac{h^2}{\varepsilon}, \quad \|\tilde{\xi}^n\|_{l^2} \lesssim \|\tilde{\xi}^n\|_{l^\infty} \lesssim \frac{\tau^2}{\varepsilon^6} + \frac{h^2}{\varepsilon}, \quad n \geq 1, \quad 0 < \varepsilon \leq 1. \quad (\text{B.4})$$

Subtracting (2.6) from (B.1), noticing (2.33), we get

$$i\delta_t \mathbf{e}_j^n = -\frac{i}{\varepsilon} \sigma_1 \delta_x \mathbf{e}_j^n + \frac{1}{\varepsilon^2} \sigma_3 \mathbf{e}_j^n + (V_j^n I_2 - A_{1,j}^n \sigma_1) \mathbf{e}_j^n + \tilde{\xi}_j^n, \quad 0 \leq j \leq M-1, \quad n \geq 1, \quad (\text{B.5})$$

where the boundary and initial conditions are given as

$$\mathbf{e}_0^n = \mathbf{e}_M^n, \quad \mathbf{e}_{-1}^n = \mathbf{e}_{M-1}^n, \quad n \geq 0, \quad \mathbf{e}_j^0 = \mathbf{0}, \quad j = 0, 1, \dots, M. \quad (\text{B.6})$$

For the first step, we have

$$\|\mathbf{e}^1\|_{l^2} = \tau \|\tilde{\xi}^0\|_{l^2} \lesssim \frac{\tau^2}{\varepsilon^4} + \frac{\tau h^2}{\varepsilon} \lesssim \frac{h^2}{\varepsilon} + \frac{\tau^2}{\varepsilon^6}. \quad (\text{B.7})$$

Denote \mathcal{E}^{n+1} for $n = 0, 1, \dots$ as

$$\mathcal{E}^{n+1} = \|\mathbf{e}^{n+1}\|_{l^2}^2 + \|\mathbf{e}^n\|_{l^2}^2 + 2 \operatorname{Re} \left(\tau h \sum_{j=0}^{M-1} (\mathbf{e}_j^{n+1})^* \sigma_1 \delta_x \mathbf{e}_j^n \right) - 2 \operatorname{Im} \left(\frac{\tau h}{\varepsilon^2} \sum_{j=0}^{M-1} (\mathbf{e}_j^{n+1})^* \sigma_3 \mathbf{e}_j^n \right); \quad (\text{B.8})$$

and under the stability condition (2.35), e.g., $\tau \leq \frac{\varepsilon^2 \tau_1 h}{\varepsilon^2 h V_{\max} + \sqrt{h^2 + \varepsilon^2 (1 + \varepsilon h A_{1, \max})^2}}$ with $\tau_1 = \frac{1}{4}$, which implies $\frac{\tau}{h} \leq \frac{1}{4}$ and $\frac{\tau}{\varepsilon^2} \leq \frac{1}{4}$, using Cauchy inequality, we can get that

$$\frac{1}{2} (\|\mathbf{e}^{n+1}\|_{l^2}^2 + \|\mathbf{e}^n\|_{l^2}^2) \leq \mathcal{E}^{n+1} \leq \frac{3}{2} (\|\mathbf{e}^{n+1}\|_{l^2}^2 + \|\mathbf{e}^n\|_{l^2}^2), \quad n \geq 0. \quad (\text{B.9})$$

It follows from (B.7) that

$$\mathcal{E}^1 \lesssim \left(\frac{h^2}{\varepsilon} + \frac{\tau^2}{\varepsilon^6} \right)^2. \quad (\text{B.10})$$

Similarly to the proof of Theorem 2.1, multiplying (B.5) from the left by $2h\tau (\mathbf{e}_j^{n+1} + \mathbf{e}_j^{n-1})^*$, taking the imaginary part, then summing for $j = 0, 1, \dots, M-1$, using Cauchy inequality, noting (B.4) and (B.9), we get for $n \geq 1$,

$$\begin{aligned} \mathcal{E}^{n+1} - \mathcal{E}^n &\lesssim h\tau \sum_{j=0}^{M-1} \left((A_{1, \max} + V_{\max}) |\mathbf{e}_j^n| + |\tilde{\xi}_j^n| \right) (|\mathbf{e}_j^{n+1}| + |\mathbf{e}_j^{n-1}|) \\ &\lesssim \tau (\mathcal{E}^{n+1} + \mathcal{E}^n) + \tau \left(\frac{h^2}{\varepsilon} + \frac{\tau^2}{\varepsilon^6} \right)^2, \quad n \geq 0. \end{aligned}$$

Summing the above inequality for $n = 1, 2, \dots, m-1$, we get

$$\mathcal{E}^m - \mathcal{E}^1 \lesssim \tau \sum_{k=1}^m \mathcal{E}^k + m\tau \left(\frac{h^2}{\varepsilon} + \frac{\tau^2}{\varepsilon^6} \right)^2, \quad 1 \leq m \leq \frac{T}{\tau}. \quad (\text{B.11})$$

Taking τ_0 sufficiently small, using the discrete Gronwall's inequality and noticing (B.10), we obtain from the above equation that

$$\mathcal{E}^m \lesssim \left(\frac{h^2}{\varepsilon} + \frac{\tau^2}{\varepsilon^6} \right)^2, \quad 1 \leq m \leq \frac{T}{\tau}, \quad (\text{B.12})$$

which immediately implies the error bound (2.36) in view of (B.9). \square

Appendix C. Proof of Theorem 3.1 for the EWI-FP method

Define the error function $\mathbf{e}^n(x)$ for $n = 0, 1, \dots$ as

$$\mathbf{e}^n(x) = \begin{pmatrix} e_1^n(x) \\ e_2^n(x) \end{pmatrix} := P_M \Phi(t_n, x) - \Phi_M^n(x) = \sum_{l=-M/2}^{M/2-1} \widehat{\xi}_l^n e^{i\mu_l(x-a)}, \quad a \leq x \leq b. \quad (\text{C.1})$$

Using the triangular inequality and standard interpolation result, we get

$$\|\Phi(t_n, x) - \Phi_M^n(x)\|_{L^2} \leq \|\Phi(t_n, x) - P_M \Phi(t_n, x)\|_{L^2} + \|\mathbf{e}^n(x)\|_{L^2} \leq h^{m_0} + \|\mathbf{e}^n(x)\|_{L^2} \quad 0 \leq n \leq \frac{T}{\tau}, \quad (\text{C.2})$$

which means that we only need estimate $\|\mathbf{e}^n(x)\|_{L^2}$.

Define the local truncation error $\xi^n(x) = \sum_{l=-M/2}^{M/2-1} \widehat{\xi}_l^n e^{i\mu_l(x-a)} \in Y_M$ of the EWI-FP (3.15) for $n \geq 0$ as

$$\widehat{\xi}_l^n = \begin{cases} (\widehat{\Phi(\tau)})_l - e^{-i\tau\Gamma_l/\varepsilon^2} (\widehat{\Phi(0)})_l + i\varepsilon^2 \Gamma_l^{-1} \left[I_2 - e^{-\frac{i\tau}{\varepsilon^2} \Gamma_l} \right] (G(0)\widehat{\Phi(0)})_l, & n = 0, \\ (\widehat{\Phi(t_{n+1})})_l - e^{-i\tau\Gamma_l/\varepsilon^2} (\widehat{\Phi(t_n)})_l + iQ_l^{(1)}(\tau) (G(t_n)\widehat{\Phi(t_n)})_l + iQ_l^{(2)}(\tau) \delta_t^- (G(t_n)\widehat{\Phi(t_n)})_l, & n \geq 1, \end{cases} \quad (\text{C.3})$$

where we write $\Phi(t)$ and $G(t)$ in short for $\Phi(t, x)$ and $G(t, x)$, respectively.

Firstly, we estimate the local truncation error $\xi^n(x)$. Multiplying both sides of the Dirac equation (2.1) by $e^{i\mu_l(x-a)}$ and integrating over the interval (a, b) , we easily recover the equations for $(\widehat{\Phi(t)})_l$, which are exactly the same as (3.6) with Φ_M being replaced by $\Phi(t, x)$. Replacing Φ_M with $\Phi(t, x)$, we use the same notations $\widehat{F}_l^n(s)$ as in (3.7) and the time derivatives of $\widehat{F}_l^n(s)$ enjoy the same properties of time derivatives of $\Phi(t, x)$. Thus, the same representation (3.10) holds for $(\widehat{\Phi(t_n)})_l$ with $n \geq 1$. From the derivation of the EWI method, it is clear that the error $\xi^n(x)$ comes from the approximations for the integrals in (3.11) and (3.12), and we have

$$\widehat{\xi}_l^0 = -i \int_0^\tau e^{\frac{i(s-\tau)}{\varepsilon^2} \Gamma_l} (\widehat{F}_l^0(s) - \widehat{F}_l^0(0)) ds = -i \int_0^\tau \int_0^s e^{\frac{i(s-\tau)}{\varepsilon^2} \Gamma_l} \partial_{s_1} \widehat{F}_l^0(s_1) ds_1 ds, \quad (\text{C.4})$$

and for $n \geq 1$

$$\widehat{\xi}_l^n = -i \int_0^\tau e^{\frac{i(s-\tau)}{\varepsilon^2} \Gamma_l} \left(\int_0^s \int_0^{s_1} \partial_{s_2 s_2} \widehat{F}_l^n(s_2) ds_2 ds_1 + s \int_0^1 \int_{\theta\tau}^\tau \partial_{\theta_1 \theta_1} \widehat{F}_l^{n-1}(\theta_1) d\theta_1 d\theta \right) ds. \quad (\text{C.5})$$

For $n = 0$, the above equalities imply $|\widehat{\xi}_l^0| \lesssim \int_0^\tau \int_0^s |\partial_{s_1} \widehat{F}_l^0(s_1)| ds_1 ds$ and by the Bessel inequality and assumptions (C) and (D), we find

$$\begin{aligned} \|\xi^0(x)\|_{L^2}^2 &= (b-a) \sum_{l=-M/2}^{M/2-1} |\widehat{\xi}_l^0|^2 \lesssim (b-a) \tau^2 \int_0^\tau \int_0^s \sum_{l=-M/2}^{M/2-1} |\partial_{s_1} \widehat{F}_l^0(s_1)|^2 ds_1 ds \\ &\lesssim \tau^2 \int_0^\tau \int_0^s \|\partial_{s_1} (G(s_1)\Phi(s_1))\|_{L^2}^2 ds_1 ds \lesssim \frac{\tau^4}{\varepsilon^4}. \end{aligned}$$

Similarly, for $n \geq 1$, we obtain

$$\begin{aligned}
\|\xi^n(x)\|_{L^2}^2 &= (b-a) \sum_{l=-M/2}^{M/2-1} |\widehat{\xi}_l^n|^2 \\
&\lesssim \tau^3 \int_0^\tau \int_0^s \int_0^{s_1} \sum_{l=-\frac{M}{2}}^{\frac{M}{2}-1} |\partial_{s_2 s_2} \widehat{F}_l^n(s_2)|^2 ds_2 ds_1 ds + \tau^3 \int_0^\tau \int_0^1 \int_{\theta\tau}^\tau s \sum_{l=-\frac{M}{2}}^{\frac{M}{2}-1} |\partial_{\theta_1 \theta_1} \widehat{F}_l^{n-1}(\theta_1)|^2 d\theta_1 d\theta ds \\
&\lesssim \tau^6 \|\partial_{tt}(G(t)\Phi(t))\|_{L^\infty([0,T];(L^2)^2)}^2 \lesssim \frac{\tau^6}{\varepsilon^8},
\end{aligned}$$

where we have used the assumptions (C) and (D). Hence, we derive that

$$\|\xi^0(x)\|_{L^2} \lesssim \frac{\tau^2}{\varepsilon^2}, \quad \|\xi^n(x)\|_{L^2} \lesssim \frac{\tau^3}{\varepsilon^4}, \quad n \geq 1. \quad (\text{C.6})$$

Now, we look at the error equations. For each fixed $l = -M/2, \dots, M/2 - 1$, subtracting (3.15) from (C.3), we obtain the equation for the error vector function as

$$\widehat{\mathbf{e}}_l^0 = \mathbf{0}, \quad \widehat{\mathbf{e}}_l^1 = \widehat{\xi}_l^0; \quad \widehat{\mathbf{e}}_l^{n+1} = e^{-i\tau\Gamma_l/\varepsilon^2} \widehat{\mathbf{e}}_l^n + \widehat{R}_l^n + \widehat{\xi}_l^n, \quad 1 \leq n \leq \frac{T}{\tau} - 1, \quad (\text{C.7})$$

where $R^n(x) = \sum_{l=-M/2}^{M/2-1} \widehat{R}_l^n e^{i\mu_l(x-a)} \in Y_M$ for $n \geq 1$ is given by

$$\widehat{R}_l^n = -iQ_l^{(1)}(\tau) \left((G(\widehat{t_n})\widehat{\Phi}(\widehat{t_n}))_l - (G(\widehat{t_n})\widehat{\Phi}_M^n)_l \right) - iQ_l^{(2)}(\tau) \left(\delta_t^- (G(\widehat{t_n})\widehat{\Phi}(\widehat{t_n}))_l - \delta_t^- (G(\widehat{t_n})\widehat{\Phi}_M^n)_l \right). \quad (\text{C.8})$$

Using the properties of the matrices $Q_l^{(1)}(\tau)$ and $Q_l^{(2)}(\tau)$, it is easy to verify that

$$\|Q_l^{(1)}(\tau)\|_2 \leq \tau, \quad \|Q_l^{(2)}(\tau)\|_2 \leq \frac{\tau^2}{2}, \quad l = -\frac{M}{2}, \dots, \frac{M}{2} - 1, \quad (\text{C.9})$$

where $\|Q\|_2$ denotes the l^2 norm of the matrix Q . Combining (C.9), (C.8) and the assumption (D), we get

$$\begin{aligned}
\|R^n(x)\|_{L^2}^2 &= (b-a) \sum_{l=-M/2}^{M/2-1} |\widehat{R}_l^n|^2 \lesssim (b-a)\tau^2 \sum_{l=-M/2}^{M/2-1} \left(\left| (\widehat{\Phi}(\widehat{t_n}))_l - (\widehat{\Phi}_M^n)_l \right|^2 + \left| (\widehat{\Phi}(\widehat{t_{n-1}}))_l - (\widehat{\Phi}_M^{n-1})_l \right|^2 \right) \\
&\lesssim \tau^2 \sum_{k=n-1}^n \|\Phi(t_k, x) - \Phi_M^k(x)\|_{L^2}^2 \lesssim \tau^2 h^{2m_0} + \tau^2 \|\mathbf{e}^n(x)\|_{L^2}^2 + \tau^2 \|\mathbf{e}^{n-1}(x)\|_{L^2}^2.
\end{aligned} \quad (\text{C.10})$$

Multiplying both sides of (C.7) by $(\widehat{\mathbf{e}}_l^{n+1} + e^{-i\tau\Gamma_l/\varepsilon^2} \widehat{\mathbf{e}}_l^n)^*$ from left, taking the real parts and using Cauchy inequality, we obtain

$$|\widehat{\mathbf{e}}_l^{n+1}|^2 - |\widehat{\mathbf{e}}_l^n|^2 \leq \tau \left[|\widehat{\mathbf{e}}_l^{n+1}|^2 + |\widehat{\mathbf{e}}_l^n|^2 \right] + \frac{|\widehat{R}_l^n|^2}{\tau} + \frac{|\widehat{\xi}_l^n|^2}{\tau}. \quad (\text{C.11})$$

Multiplying the above inequality by $b-a$ and summing together for $l = -M/2, \dots, M/2 - 1$, in view of the Bessel inequality, we obtain

$$\|\mathbf{e}^{n+1}(x)\|_{L^2}^2 - \|\mathbf{e}^n(x)\|_{L^2}^2 \lesssim \tau (\|\mathbf{e}^{n+1}(x)\|_{L^2}^2 + \|\mathbf{e}^n(x)\|_{L^2}^2) + \frac{1}{\tau} \|R^n(x)\|_{L^2}^2 + \frac{1}{\tau} \|\xi^n(x)\|_{L^2}^2, \quad n \geq 1. \quad (\text{C.12})$$

Summing (C.12) for $n = 1, \dots, m-1$, using (C.10) and (C.6), we derive

$$\|\mathbf{e}^m(x)\|_{L^2}^2 - \|\mathbf{e}^1(x)\|_{L^2}^2 \lesssim \tau \sum_{k=1}^m \|\mathbf{e}^k(x)\|_{L^2}^2 + \frac{m\tau^5}{\varepsilon^8} + m\tau h^{2m_0}, \quad 1 \leq m \leq \frac{T}{\tau}. \quad (\text{C.13})$$

Since $\|\mathbf{e}^0(x)\|_{L^2} = 0$ and $\|\mathbf{e}^1(x)\|_{L^2} \lesssim \frac{\tau^2}{\varepsilon^2} \lesssim \frac{\tau^2}{\varepsilon^4}$, the discrete Gronwall's inequality will imply that for sufficiently small τ ,

$$\|\mathbf{e}^m(x)\|_{L^2}^2 \lesssim h^{2m_0} + \frac{\tau^4}{\varepsilon^8}, \quad 1 \leq m \leq \frac{T}{\tau}. \quad (\text{C.14})$$

Combining (C.2) and (C.14), we draw the conclusion (3.24). \square

Appendix D. Extensions of the EWI-FS (3.14)-(3.15) and TSFP (4.4) in 2D and 3D

The EWI-FS (3.14)-(3.15), EWI-FP (3.17)-(3.18) and TSFP (4.4) can be easily extended to 2D and 3D with tensor grids by modifying the matrices Γ_l in (3.8) and $G(t, x)$ in (4.5) in the TSFP case. For the reader's convenience, we present the modifications of Γ_l in (3.8) and $G(t, x)$ in (4.5) in 2D and 3D as follows.

For the Dirac equation (1.21) in 2D, i.e. we take $d = 2$ in (1.21). The problem is truncated on $\Omega = (a_1, b_1) \times (a_2, b_2)$ with mesh sizes $h_1 = (b_1 - a_1)/M_1$ and $h_2 = (b_2 - a_2)/M_2$ (M_1, M_2 two even positive integers) in the x - and y -direction, respectively. The wave function Φ is a two-component vector, and the matrix Γ_l in (3.8) will be replaced by

$$\Gamma_{jk} = \begin{pmatrix} 1 & \varepsilon\mu_j^{(1)} - i\varepsilon\mu_k^{(2)} \\ \varepsilon\mu_j^{(1)} + i\varepsilon\mu_k^{(2)} & -1 \end{pmatrix}, \quad \mu_j^{(1)} = \frac{2j\pi}{b_1 - a_1}, \quad \mu_k^{(2)} = \frac{2k\pi}{b_2 - a_2}, \quad (\text{D.1})$$

where $-\frac{M_1}{2} \leq j \leq \frac{M_1}{2} - 1$, $-\frac{M_2}{2} \leq k \leq \frac{M_2}{2} - 1$, and the Schur decomposition $\Gamma_{jk} = Q_{jk} D_{jk} Q_{jk}^*$ is given as

$$Q_{jk} = \begin{pmatrix} \frac{1+\delta_{jk}}{\sqrt{2\delta_{jk}(1+\delta_{jk})}} & \frac{-\varepsilon\mu_j^{(1)} + i\varepsilon\mu_k^{(2)}}{\sqrt{2\delta_{jk}(1+\delta_{jk})}} \\ \frac{\varepsilon\mu_j^{(1)} + i\varepsilon\mu_k^{(2)}}{\sqrt{2\delta_{jk}(1+\delta_{jk})}} & \frac{1+\delta_{jk}}{\sqrt{2\delta_{jk}(1+\delta_{jk})}} \end{pmatrix}, \quad D_{jk} = \begin{pmatrix} \delta_{jk} & 0 \\ 0 & -\delta_{jk} \end{pmatrix}, \quad \delta_{jk} = \sqrt{1 + \varepsilon^2(\mu_j^{(1)})^2 + \varepsilon^2(\mu_k^{(2)})^2}. \quad (\text{D.2})$$

The matrix $\int_{t_n}^{t_{n+1}} G(t, x) dt$ in (4.5) becomes $\int_{t_n}^{t_{n+1}} G(t, \mathbf{x}) dt$ and the Schur decomposition $\int_{t_n}^{t_{n+1}} G(t, \mathbf{x}) dt = P_{\mathbf{x}} \Lambda_{\mathbf{x}} P_{\mathbf{x}}^*$ with $V_{\mathbf{x}}^{(1)} = \int_{t_n}^{t_{n+1}} V(t, \mathbf{x}) dt$, $A_{l, \mathbf{x}}^{(1)} = \int_{t_n}^{t_{n+1}} A_l(t, \mathbf{x}) dt$ for $l = 1, 2$, $\lambda_{\mathbf{x}}^{(1)} = \sqrt{|A_{1, \mathbf{x}}^{(1)}|^2 + |A_{2, \mathbf{x}}^{(1)}|^2}$, $\Lambda_{\mathbf{x}} = \text{diag}(\Lambda_{\mathbf{x}, -}, \Lambda_{\mathbf{x}, +})$, $\Lambda_{\mathbf{x}, \pm} = V_{\mathbf{x}}^{(1)} \pm \lambda_{\mathbf{x}}^{(1)}$, and $P_{\mathbf{x}} = I_2$ if $\lambda_{\mathbf{x}}^{(1)} = 0$ and otherwise

$$P_{\mathbf{x}} = \begin{pmatrix} \frac{1}{\sqrt{2}} & \frac{A_{1, \mathbf{x}}^{(1)} - iA_{2, \mathbf{x}}^{(1)}}{\sqrt{2\lambda_{\mathbf{x}}^{(1)}}} \\ \frac{A_{1, \mathbf{x}}^{(1)} + iA_{2, \mathbf{x}}^{(1)}}{\sqrt{2}} & \frac{1}{\sqrt{2\lambda_{\mathbf{x}}^{(1)}}} \end{pmatrix}. \quad (\text{D.3})$$

For the Dirac equation (1.9) in 3D, i.e. we take $d = 3$ in (1.9). The problem is truncated on $\Omega = (a_1, b_1) \times (a_2, b_2) \times (a_3, b_3)$ with mesh sizes $h_1 = (b_1 - a_1)/M_1$, $h_2 = (b_2 - a_2)/M_2$ and $h_3 = (b_3 - a_3)/M_3$ (M_1, M_2, M_3 three even positive integers) in x -, y - and z -direction, respectively. The wave function Ψ is a four-component vector, and the matrix Γ_l in (3.8) will be replaced by Γ_{jkl} as:

$$\Gamma_{jkl} = \begin{pmatrix} 1 & 0 & \varepsilon\mu_l^{(3)} & \varepsilon\mu_j^{(1)} - i\varepsilon\mu_k^{(2)} \\ 0 & 1 & \varepsilon\mu_j^{(1)} + i\varepsilon\mu_k^{(2)} & -\varepsilon\mu_l^{(3)} \\ \varepsilon\mu_l^{(3)} & \varepsilon\mu_j^{(1)} - i\varepsilon\mu_k^{(2)} & -1 & 0 \\ \varepsilon\mu_j^{(1)} + i\varepsilon\mu_k^{(2)} & -\varepsilon\mu_l^{(3)} & 0 & -1 \end{pmatrix}, \quad (\text{D.4})$$

where $-\frac{M_1}{2} \leq j \leq \frac{M_1}{2} - 1$, $-\frac{M_2}{2} \leq k \leq \frac{M_2}{2} - 1$, $-\frac{M_3}{2} \leq l \leq \frac{M_3}{2} - 1$ and

$$\mu_j^{(1)} = \frac{2j\pi}{b_1 - a_1}, \quad \mu_k^{(2)} = \frac{2k\pi}{b_2 - a_2}, \quad \mu_l^{(3)} = \frac{2l\pi}{b_3 - a_3}. \quad (\text{D.5})$$

The eigenvalues of Γ_{jkl} are

$$\delta_{jkl}, \delta_{jkl}, -\delta_{jkl}, -\delta_{jkl}, \quad \text{with} \quad \delta_{jkl} = \sqrt{1 + \varepsilon^2 |\mu_j^{(1)}|^2 + \varepsilon^2 |\mu_k^{(2)}|^2 + \varepsilon^2 |\mu_l^{(3)}|^2}.$$

The corresponding eigenvectors are

$$\mathbf{v}_{jkl}^{(1)} = \begin{pmatrix} 1 + \delta_{jkl} \\ 0 \\ \varepsilon\mu_l^{(3)} \\ \varepsilon\mu_j^{(1)} + i\varepsilon\mu_k^{(2)} \end{pmatrix}, \quad \mathbf{v}_{jkl}^{(2)} = \begin{pmatrix} 0 \\ 1 + \delta_{jkl} \\ \varepsilon\mu_j^{(1)} - i\varepsilon\mu_k^{(2)} \\ -\varepsilon\mu_l^{(3)} \end{pmatrix}, \quad \mathbf{v}_{jkl}^{(3)} = \begin{pmatrix} -\varepsilon\mu_l^{(3)} \\ -\varepsilon\mu_j^{(1)} - i\varepsilon\mu_k^{(2)} \\ 1 + \delta_{jkl} \\ 0 \end{pmatrix}, \quad \mathbf{v}_{jkl}^{(4)} = \begin{pmatrix} -\varepsilon\mu_j^{(1)} + i\varepsilon\mu_k^{(2)} \\ \varepsilon\mu_l^{(3)} \\ 0 \\ 1 + \delta_{jkl} \end{pmatrix}.$$

Then the Schur decomposition $\Gamma_{jkl} = Q_{jkl} D_{jkl} Q_{jkl}^*$ is given as

$$D_{jkl} = \text{diag}(\delta_{jkl}, \delta_{jkl}, -\delta_{jkl}, -\delta_{jkl}), \quad Q_{jkl} = \frac{1}{\sqrt{2\delta_{jkl}(1 + \delta_{jkl})}} \begin{pmatrix} \mathbf{v}_{jkl}^{(1)} & \mathbf{v}_{jkl}^{(2)} & \mathbf{v}_{jkl}^{(3)} & \mathbf{v}_{jkl}^{(4)} \end{pmatrix}.$$

The matrix $\int_{t_n}^{t_{n+1}} G(t, x) dt$ in (4.5) becomes $\int_{t_n}^{t_{n+1}} G(t, \mathbf{x}) dt$ and the Schur decomposition $\int_{t_n}^{t_{n+1}} G(t, \mathbf{x}) dt = P_{\mathbf{x}} \Lambda_{\mathbf{x}} P_{\mathbf{x}}^*$ with $V_{\mathbf{x}}^{(1)} = \int_{t_n}^{t_{n+1}} V(t, \mathbf{x}) dt$, $A_{l, \mathbf{x}}^{(1)} = \int_{t_n}^{t_{n+1}} A_l(t, \mathbf{x}) dt$ for $l = 1, 2, 3$, $\lambda_{\mathbf{x}}^{(1)} = \sqrt{|A_{1, \mathbf{x}}^{(1)}|^2 + |A_{2, \mathbf{x}}^{(1)}|^2 + |A_{3, \mathbf{x}}^{(1)}|^2}$, $\Lambda_{\mathbf{x}} = \text{diag}(\Lambda_{\mathbf{x}, -}, \Lambda_{\mathbf{x}, -}, \Lambda_{\mathbf{x}, +}, \Lambda_{\mathbf{x}, +})$, $\Lambda_{\mathbf{x}, \pm} = V_{\mathbf{x}}^{(1)} \pm \lambda_{\mathbf{x}}^{(1)}$, and $P_{\mathbf{x}} = I_4$ if $\lambda_{\mathbf{x}}^{(1)} = 0$ and otherwise

$$\mathbf{u}_{\mathbf{x}}^{(1)} = \begin{pmatrix} \frac{1}{\sqrt{2}} \\ 0 \\ \frac{A_{3, \mathbf{x}}^{(1)}}{\sqrt{2\lambda_{\mathbf{x}}^{(1)}}} \\ \frac{A_{1, \mathbf{x}}^{(1)} + iA_{2, \mathbf{x}}^{(1)}}{\sqrt{2\lambda_{\mathbf{x}}^{(1)}}} \end{pmatrix}, \quad \mathbf{u}_{\mathbf{x}}^{(2)} = \begin{pmatrix} 0 \\ \frac{1}{\sqrt{2}} \\ \frac{A_{1, \mathbf{x}}^{(1)} - iA_{2, \mathbf{x}}^{(1)}}{\sqrt{2\lambda_{\mathbf{x}}^{(1)}}} \\ \frac{-A_{3, \mathbf{x}}^{(1)}}{\sqrt{2\lambda_{\mathbf{x}}^{(1)}}} \end{pmatrix}, \quad \mathbf{u}_{\mathbf{x}}^{(3)} = \begin{pmatrix} \frac{-A_{3, \mathbf{x}}^{(1)}}{\sqrt{2\lambda_{\mathbf{x}}^{(1)}}} \\ \frac{\sqrt{2\lambda_{\mathbf{x}}^{(1)}}}{-A_{1, \mathbf{x}}^{(1)} - iA_{2, \mathbf{x}}^{(1)}} \\ \frac{1}{\sqrt{2}} \\ 0 \end{pmatrix}, \quad \mathbf{u}_{\mathbf{x}}^{(4)} = \begin{pmatrix} \frac{-A_{1, \mathbf{x}}^{(1)} + iA_{2, \mathbf{x}}^{(1)}}{\sqrt{2\lambda_{\mathbf{x}}^{(1)}}} \\ \frac{A_{3, \mathbf{x}}^{(1)}}{\sqrt{2\lambda_{\mathbf{x}}^{(1)}}} \\ 0 \\ \frac{1}{\sqrt{2}} \end{pmatrix}.$$

For the Dirac equation (1.9) in 2D, we simply let $\mu_l^{(3)} = 0$, $A_3(t, \mathbf{x}) \equiv 0$ in the above 3D case; and for the Dirac equation (1.9) in 1D, we let $\mu_k^{(2)} = \mu_l^{(3)} = 0$, $A_2(t, \mathbf{x}) = A_3(t, \mathbf{x}) \equiv 0$ in the above 3D case. Then the EWI-FP (3.17)-(3.18) and TSFP (4.4) can be designed accordingly for the Dirac equation (1.9) in 2D and 1D.
