# WHAT ARE MY COSTS

# of raising watermelons?

R. J. Hilsenkopf and R. C. Suter

Cooperative Extension Service PURDUE UNIVERSITY Lafayette, Indiana Farmers often wonder what it costs to grow and harvest a crop or what it costs to raise a particular class of livestock. Enterprise cost studies are occasionally available, yet these data are not always applicable in an individual situation.

The purpose of this publication is to report some dollar costs and returns from growers and to outline how a grower can either make future estimates or simply record his own production costs and dollar returns. This is essentially a do-it-yourself kit. A sharp pencil and a little time are all that are required.

Read through the entire publication before attempting to develop your own costs and returns. At the end, several sets of budgeting sheets are included. These are identical with the data presented first. A grower may use these blank sheets to budget his own costs and returns.

Budgeting Technique

Budgeting is a method used to determine presentday costs of production or to develop plans for future use of certain resources, using current capital outlays. The present-day prices used in the technique more nearly reflect today's situation, or those costs that can be expected. This approach becomes more meaningful than cost accounting which has been used to a large extent in the past.

Answers derived in the process depend, of course, on the data put into the budget. Answers depend on:

- Physical inputs used (labor, power, equipment, seed, fertilizer)
- Cost data or prices (land values, labor rates, other costs)
- Methods of budgeting, along with degree of accuracy desired
- Judgment of the person doing the job

Each grower can develop his own production costs along with the probable results he can obtain. In doing so he can use his own physical coefficients, his own basic assumptions or values, the costs he expects to pay and the prices he himself can command. Final results are of course determined by the amounts of resources he uses and the value he places on them. Production Costs Per 10-Sash Bed and Per Acre

In 1957 the average cost of raising watermelon plants was \$85.15 per 10-sash bed or \$11.20 per acre of watermelons planted (Table 1). These figures are based on:

1. A concrete block foundation and window-glass sash with estimated service lives of 50 and 25 years, respectively.

2. Present-day capital outlays of \$30.78 (foundation) and \$106.52 (sash).

3. Annual ownership costs of 5.25 and 10.25 percent, respectively.

4. Typical labor and material inputs as used by 46 melon growers.

The average cost of growing watermelons (including the cover crop and the plants) was \$124.93 per acre (Table 2). This figure is based on:

1. A cost of \$11.20 per acre for plants.

2. A land value of \$296 per acre.

3. An average of 24.0 hours of labor used to grow the crop.

4. A 2-plow tractor, along with other equipment of a complementary size (except for cultivating where a 1-plow tractor and 1-row cultivator were used).

5. A mechanical transplanter.

6. A fertilizer application of 73 pounds nitrogen, 46 pounds phosphate and 46 pounds potash.

7. A yield of 7.5 tons of watermelons per acre which required an average of 25.4 hours of labor for harvesting.

#### Dollar Returns Per Acre and Per Hour

Watermelon yields vary from year to year as well as from farm-to-farm. In 1957 growers harvested an average of 7.5 tons per acre (Table 3). However, a typical yield is 9.4 tons. Many growers stated that their 1957 yields were the lowest they had ever harvested. This was due, they thought, to the above-normal rainfall during the early part of the growing season and heavy winds that occurred at the time melons were setting on the vine.

The average farm price received by growers in 1957 was \$31 per ton. However, in 1956 they received only \$16. The higher price in 1957 was due to the short crop of watermelons, not only in Indiana but in the United States as a whole. The average price for the period 1955 through 1958 was \$21.50 per ton. Yields and prices tend to vary inversely; hence, there is less year-to-year variation in per-acre returns than there is in either yields or prices received.

A grower with an average yield in 1957 obtained a per-acre return of \$232.50. The price that year due to the short supply of melons more than offset the lower yields obtained. The per acre returns for a typical year is \$202.10.

The dollar returns per hour of labor in 1957 averaged \$2.96 (average yield) and \$4.20 (high yield) per hour. These figures are above those in a typical year (\$2.14 and \$3.09) mainly because of the higher prices received.

	195	<b>7</b>	Typical	year
Physical coefficients	Average	High	Average	High
and prices	yield	yield	yield	yield
Yield per acre	7.5	11.5	9.4	14.6
Price per ton	\$ 31.00	\$ 31.00	\$ 21.50	\$ 21.50

Returns to labor and management	a			
Per acre	\$162.57	\$283.69	\$130.85	\$238.81
Per hour	2.96	4.20	2.14	3.09

Table 3. Dollar returns to labor and management, 46 farms, Southwestern Indiana, 1957.

a/ After paying all other costs.

Farm-to-farm Variations in Amounts of Resource Use and Yields

Considerable farm-to-farm variation occurs in the amounts of resource use.

1. The present market land value on the typical farm was \$296 per acre; however, on a third of the farms land values averaged \$370 per acre, on another third they averaged only \$212 per acre (Table 4).

2. The variation in the amount of labor and tractor power used was sizeable. For example, the hotbed operation required an average of 42.6 hours of labor per 10sash bed. However, a third of the growers spent only 27.7 hours; another third averaged 62.6 hours.

3. In 1957 most growers transplanted melons by hand, they had an average cost of \$9.24 (Table 5). In 1958 11 growers were transplanting melons with a mechanical transplanter. Their costs averaged \$5.70 per acre.

4. The typical grower applied 73 pounds nitrogen, 46 pounds phosphate and 46 pounds potash. However, a third of the growers averaged 114 pounds nitrogen, 74 pounds phosphate and 73 pounds potash; another third averaged 38 pounds nitrogen, 20 pounds phosphate and 20 pounds potash. In 1957 there was little or no relationship between level of fertilizer application and watermelon yields.

Yields also vary widely from farm to farm. In 1957 one-third of the growers averaged 11.5 tons per acre, 66 percent above average; another third harvested an average of only 5.3 tons per acre. The farm to farm variation in yields is considerably greater than the variation from year to year.

Table 4. Variations in resource use and watermelon yields, 46 farms, Southwestern Indiana, 1957.

## Table 5. Transplanting costs: hand vs. machine, Southwestern Indiana, 1957 and 1958.

### Some Cost Rates

1. Labor, \$ 1.00 per hour. The farm operator and some family help is worth more, yet hired labor (for transplanting, hoeing, turning vines and harvesting) in the Knox, Gibson and Daviess area was available for considerably less--\$0.75 per hour.

## 2. Fertilizer prices (April 1957)

Lime, \$3.10 per ton; Nitrogen, \$83.00 per ton or \$0.124 per lb; Phosphate, \$34.96 per ton or \$0.092 per lb; Potash, \$51.90 per ton or \$0.047 per lb.

3. A 2-plow tractor, \$1.20 per hour. A 1-plow tractor, \$0.95 per hour. 4. Machinery and equipment cost rates.

Warren, professor of Horticulture at Purdue, and R. M. Frederick, former district horticulturist of Vincennes, Indiana.

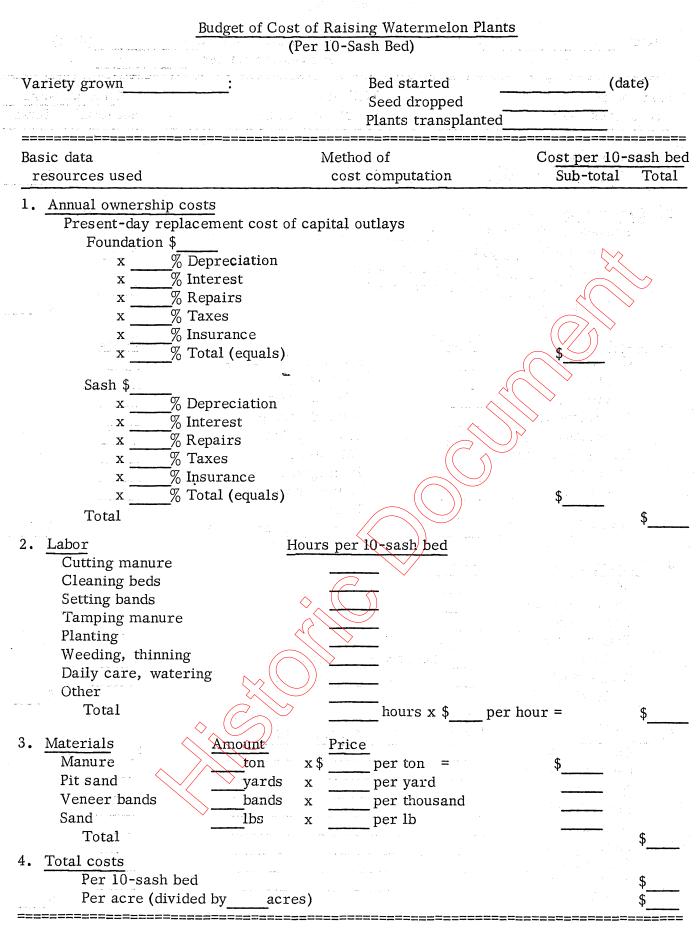

#### Reference

Purdue Agricultural Experiment Station Research Bulletin 729. The data presented are the results of a survey of 46 melon growers in Knox, Gibson and Daviess Counties in 1957. In 1954, 382 farms in these three leading melon-producing counties produced 74 percent of the watermelons raised. To the families on these farms, melons are a major source of income.

Of the 46 growers interviewed 18 were owner-operators, operating an average of 130 acres. Nineteen of them were partowners; they owned an average of 139 acres, and, in addition, rented 139 acres. Nine were tenant-operators and farmed an average of 212 acres.

The farms averaged 186 total farm acres, with 155 acres in crops. An average of 28 acres of watermelons and 11 acres of cantaloupes were raised; melons thus accounted for 25 percent of the total crop acres.
