Rapport de recherche n° 4358 — January 18, 2002 — 14 pages

Abstract: In this report we solve the basic fractional analogue of the classical linear-quadratic Gaussian regulator problem in continuous-time. For a completely observable controlled linear system driven by a fractional Brownian motion, we describe explicitly the optimal control policy which minimizes a quadratic performance criterion.

Key-words: Fractional Brownian motion. Linear system. Optimal control. Quadratic payoff.

Sur le problème du régulateur linéaire-quadratique sous perturbation brownienne fractionnaire et observation complète

Résumé : Dans ce rapport nous résolvons l'analogie fractionnaire de base du problème du régulateur linéaire-quadratique gaussien en temps continu. Pour un système contrôlé complètement observé gouverné par un mouvement brownien fractionnaire, nous décrivons explicitement la politique de contrôle optimale qui minimise un critère de performance quadratique.

Mots-clé : Mouvement brownien fractionnaire. Système linéaire. Contrôle optimal. Coût quadratique.

1 Introduction

Several contributions in the literature have been already devoted to the extension of the classical theory of continuous-time stochastic systems driven by Brownian motions to analogues in which the driving processes are fractional Brownian motions (fBm's for short). The tractability of the standard problems in prediction, parameter estimation and filtering is now rather well understood (see, *e.g.*, [4], [10], [8], [6], [7], [11] and references therein). Concerning optimal control problems, as far as we know, it is far from fully demonstrated (nevertheless, see [5] for a recent attempt in a general setting). Here our aim is to illustrate the actual solvability of control problems by exhibiting an explicit solution for the case of the simplest linear-quadratic model.

We deal with the fractional analogue of the so-called linear-quadratic Gaussian regulator problem in one dimension. The real-valued state process $X = (X_t, t \in [0, T])$ is governed by the stochastic differential equation

$$dX_t = a(t)X_t dt + b(t)u_t dt + c(t)dB_t^H, \quad t \in [0, T], \quad X_0 = x, \quad (1)$$

which is as usual interpreted as an integral equation. Here x is a fixed initial condition, $B^H = (B_t^H, t \in [0, T])$ is a normalized fBm with the Hurst parameter H in $[1/2, 1)$ and the coefficients $a = (a(t), t \in [0, T])$, $b = (b(t), t \in [0, T])$ and $c = (c(t), t \in [0, T])$ are fixed (deterministic) continuous functions. We suppose that X is completely observed and that a closed-loop control of the system is available in the sense that at each time $t \in [0, T]$ one may choose the input u_t in view of the passed observations $\{X_s, s \leq t\}$ in order to drive the corresponding state, $X_t = X_t^u$ say. Then, given a cost function which evaluates the performance of the control actions, the classical problem of controlling the system dynamics on the time interval $[0, T]$ so as to minimize this cost occurs. Here we consider the quadratic payoff J defined for a control policy $u = (u_t, t \in [0, T])$ by

$$J(u) = \frac{1}{2} \mathbb{E} \left\{ q_T X_T^2 + \int_0^T [q(t)X_t^2 + r(t)u_t^2] dt \right\}, \quad (2)$$

where q_T is a positive constant and $q = (q(t), t \in [0, T])$ and $r = (r(t), t \in [0, T])$ are fixed (deterministic) positive continuous functions. It is well-known that when $H = 1/2$ and hence the noise in (1) is a Brownian motion, then (see, *e.g.*, [1] and [9]), the solution \bar{u} to the corresponding problem, called the optimal control, is provided for all $t \in [0, T]$ by the instantaneous linear feedback

$$\bar{u}_t = -\frac{b(t)}{r(t)} \pi(t) \bar{X}_t; \quad \bar{X}_t = X_t^{\bar{u}}, \quad (3)$$

where $\pi = (\pi(t), t \in [0, T])$ is the unique nonnegative solution of the backward Riccati differential equation

$$\dot{\pi}(t) = -2a(t)\pi(t) - q(t) + \frac{b^2(t)}{r(t)} \pi^2(t); \quad \pi(T) = q_T. \quad (4)$$

Moreover the optimal cost $J(\bar{u})$ is given by

$$J(\bar{u}) = \frac{1}{2} \left\{ \pi(0) x^2 + \int_0^T \pi(t) c^2(t) dt \right\}. \quad (5)$$

Our main goal here is to show that actually when the system (1) is driven by a fBm with some $H \in (1/2, 1)$ instead of a Brownian motion, an explicit solution to the optimal control problem under the performance criterion (2) is still available.

The paper is organized as follows. At first in Section 2, we fix some notations and preliminaries. Then, in Section 3, the concerned closed-loop control problem is solved : the optimal control is defined as a linear but not instantaneous feedback which involves the solution of a Volterra type integral equation; moreover a representation of the optimal cost is also provided. Globally, the solution of the problem is expressed in terms of the solutions of a family of three-dimensional backward differential Riccati equations which for $H = 1/2$ actually all reduce to the standard one-dimensional Riccati equation (4).

2 Preliminaries

In what follows all random variables and processes are defined on a given stochastic basis $(\Omega, \mathcal{F}, \mathbf{P})$. Moreover the *natural filtration* of a process is understood as the \mathbf{P} -completion of the filtration generated by this process.

Here, for some fixed $T > 0$ and $H \in [1/2, 1)$, $B^H = (B_t^H, t \in [0, T])$ is a *normalized fractional Brownian motion* on $[0, T]$ with Hurst parameter means that B^H is a Gaussian process with continuous paths such that $B_0^H = 0$, $\mathbb{E}B_t^H = 0$ and

$$\mathbb{E}B_s^H B_t^H = \frac{1}{2} [s^{2H} + t^{2H} - |s - t|^{2H}], \quad 0 \leq s, t \leq T. \quad (1)$$

Of course the fBm reduces to the standard Brownian motion when $H = 1/2$. For $H \neq 1/2$, the fBm is outside the world of semimartingales but a theory of stochastic integration w.r. to fBm has been developed (see, *e.g.*, [2] or [3]). Actually the case of deterministic integrands, which is sufficient for the purpose of the present paper, is easy to handle (see, *e.g.*, [10]).

- *Fundamental martingale associated to B^H* - There are simple integral transformations which change the fBm to martingales (see [10], [8] and [11]). In particular, defining for $0 < s < t \leq T$

$$k_H(t, s) = \kappa_H^{-1} s^{\frac{1}{2}-H} (t-s)^{\frac{1}{2}-H}; \quad \kappa_H = 2H\Gamma(3/2-H)\Gamma(H+1/2), \quad (2)$$

$$w_t^H = \lambda_H^{-1} t^{2-2H}; \quad \lambda_H = \frac{2H\Gamma(3-2H)\Gamma(H+1/2)}{\Gamma(3/2-H)}, \quad (3)$$

$$M_t^H = \int_0^t k_H(t, s) dB_s^H, \quad (4)$$

then the process M^H is a Gaussian martingale, called in [10] the *fundamental martingale*, whose variance function $\langle M^H \rangle$ is nothing but the function w^H . Actually, the natural filtration of M^H coincides with the natural filtration (\mathcal{F}_t^H) of B^H . In particular, we have the direct consequence of the results of [8] that, given a suitably regular deterministic function $c = (c(t), t \in [0, T])$, the following representation holds :

$$\int_0^t c(s)dB_s^H = \int_0^t K_H^c(t, s)dM_s^H, \quad (5)$$

where for $H \in (1/2, 1)$ the function K_H^c is given by

$$K_H^c(t, s) = H(2H - 1) \int_s^t c(r)r^{H-\frac{1}{2}}(r-s)^{H-\frac{3}{2}} dr, \quad 0 \leq s \leq t, \quad (6)$$

and for $H = 1/2$ the convention $K_{1/2}^c(t, \cdot) \equiv c$ for all t is used. Conversely, given a suitably regular deterministic function $f = (f(t), t \in [0, T])$, we have also :

$$\int_0^t f(s)dM_s^H = \int_0^t k_H^f(t, s)dB_s^H, \quad (7)$$

where the function k_H^f is given by

$$k_H^f(t, s) = -\kappa_H^{-1} s^{\frac{1}{2}-H} \frac{d}{ds} \int_s^t (r-s)^{\frac{1}{2}-H} f(r)dr. \quad (8)$$

- *Admissible controls* - Let \mathcal{U}_H the class of (\mathcal{F}_t^H) -adapted processes $u = (u_t, t \in [0, T])$ such that the stochastic differential equation (1) has a unique strong solution X^u which satisfies $J(u) < +\infty$, where $J(u)$ is evaluated according to (2) with $X = X^u$. Of course then X^u is a (\mathcal{F}_t^H) -adapted process. Actually, as mentioned in Section 1, for control purpose we are interested in closed-loop policies. So, we introduce the *class of admissible controls* as the class \mathcal{U}_{ad} of those u 's in \mathcal{U}_H which are (\mathcal{F}_t^u) -adapted processes where (\mathcal{F}_t^u) is the natural filtration of the corresponding state process X^u . For $u \in \mathcal{U}_{ad}$, the pair (u, X^u) is called an *admissible pair* and if $\bar{u} \in \mathcal{U}_{ad}$ is such that

$$J(\bar{u}) = \inf\{J(u), u \in \mathcal{U}_{ad}\},$$

then it is called an *optimal control* and (\bar{u}, \bar{X}) , where $\bar{X} = X^{\bar{u}}$, is called an *optimal pair* and the quantity $J(\bar{u})$ is called the *optimal cost*.

3 Solution of the optimal control problem

In order to state our main result, starting from the solution π of the Riccati equation (4), for any fixed $s \in [0, T]$, we introduce auxiliary deterministic functions $\gamma(\cdot, s) = (\gamma(t, s), t \in$

$[s, T]$) and $\lambda(\cdot, s) = (\lambda(t, s), t \in [s, T])$. They are the solutions of the following backward differential equations in the variable t on $[s, T]$:

$$\dot{\gamma}(\cdot, s) = -a[\gamma(\cdot, s) + K_H^c(\cdot, s)\pi] - qK_H^c(\cdot, s) + \frac{b^2}{r}\pi\gamma(\cdot, s); \quad \gamma(T, s) = q_T K_H^c(T, s), \quad (1)$$

$$\dot{\lambda}(\cdot, s) = -2aK_H^c(\cdot, s)\gamma(\cdot, s) - q[K_H^c(\cdot, s)]^2 + \frac{b^2}{r}\gamma^2(\cdot, s); \quad \lambda(T, s) = q_T [K_H^c(T, s)]^2. \quad (2)$$

Let us mention that actually the 2×2 matrix-valued function $\Gamma(\cdot, s) = (\Gamma(t, s), t \in [s, T])$ where

$$\Gamma(t, s) = \begin{pmatrix} \pi(t) & \gamma(t, s) \\ \gamma(t, s) & \lambda(t, s) \end{pmatrix},$$

is the unique nonnegative symmetric solution of the backward Riccati equation

$$\begin{aligned} \dot{\Gamma}(\cdot, s) &= -a\{\mathcal{K}_H^c(\cdot, s)e_1'\Gamma(\cdot, s) + \Gamma(\cdot, s)e_1[\mathcal{K}_H^c(\cdot, s)]'\} \\ &\quad -q\mathcal{K}_H^c(\cdot, s)[\mathcal{K}_H^c(\cdot, s)]' + \frac{b^2}{r}\Gamma(\cdot, s)e_1e_1'\Gamma(\cdot, s); \quad \Gamma(T, s) = q_T \mathcal{K}_H^c(T, s)[\mathcal{K}_H^c(T, s)]', \end{aligned}$$

with the vectors e_1 and $\mathcal{K}_H^c(t, s)$ in \mathbb{R}^2 given by

$$e_1 = \begin{pmatrix} 1 \\ 0 \end{pmatrix}; \quad \mathcal{K}_H^c(t, s) = \begin{pmatrix} 1 \\ K_H^c(t, s) \end{pmatrix}.$$

We shall use the following notations :

$$\bar{\gamma}(s) = \gamma(s, s); \quad \bar{\lambda}(s) = \lambda(s, s), \quad (3)$$

where $\gamma(\cdot, s)$ and $\lambda(\cdot, s)$ are defined by equations (1) and (2) respectively. We introduce also the function $\bar{k}(t, s) = k_H^{\bar{\gamma}}(t, s)$ by substituting $\bar{\gamma}$ for f in the definition (8), i.e. :

$$\bar{k}(t, s) = -\kappa_H^{-1} s^{\frac{1}{2}-H} \frac{d}{ds} \int_s^t (r-s)^{\frac{1}{2}-H} \bar{\gamma}(r) dr. \quad (4)$$

Theorem 1 *There exists a unique optimal control \bar{u} in \mathcal{U}_{ad} and the optimal pair (\bar{u}, \bar{X}) is governed on $[0, T]$ by the system*

$$\bar{u}_t = -\frac{b(t)}{r(t)}[\pi(t)\bar{X}_t + \bar{v}_t]; \quad \bar{X}_t = X_t^{\bar{u}}, \quad (5)$$

$$\bar{v}_t = \int_0^t [-a(s) + \frac{b^2(s)}{r(s)}\pi(s)]\bar{v}_s ds + \int_0^t [\frac{\bar{k}(t, s)}{c(s)} - \pi(s)]\{d\bar{X}_s - [a(s)\bar{X}_s + b(s)\bar{u}_s]ds\}, \quad (6)$$

where π and \bar{k} are defined by (4) and (4) respectively. Moreover the optimal cost is given by

$$J(\bar{u}) = \frac{1}{2}\{\pi(0)x^2 + \int_0^T \bar{\lambda}(t)dw_t^H\}, \quad (7)$$

where $\bar{\lambda}$ is defined by (3).

Remark 1 (a) Observe that in the case $H = 1/2$, for all $0 \leq s \leq t \leq T$, the entries $\gamma(t, s)$, $\lambda(t, s)$ and $\bar{k}(t, s)$ reduce to $\pi(t)c(s)$, $\pi(t)c^2(s)$ and $\pi(s)c(s)$ respectively. Hence, it is readily seen that $\bar{v} \equiv 0$, $\bar{u} = -(b/r)\pi\bar{X}$ and $\bar{\lambda}(t)dw_t^H = \pi(t)c^2(t)dt$. So, finally, the statement in Theorem 1 reduces to the well-known result recalled in Section 1.

(b) It is worth to mention that actually the additional term \bar{v}_t which appears in the case $H > 1/2$ can be interpreted in terms of the predictors at time t of the noise component $\tilde{B}_\tau = \int_0^\tau c(s)dB_s^H$, $t \leq \tau \leq T$ based on the observed optimal dynamics $(\bar{X}_s, s \leq t)$ up to time t . Precisely, one can rewrite

$$\bar{v}_t = \int_t^T \phi(\tau, t)\pi(\tau)d\hat{B}_\tau^t, \quad (8)$$

where $\hat{B}_\tau^t = \mathbb{E}(\tilde{B}_\tau/\mathcal{F}_t^u)$ and

$$\phi(\tau, t) = \exp\left\{\int_t^\tau \left[a(u) - \frac{b^2(u)}{r(u)}\pi(u)\right]du\right\}. \quad (9)$$

This will be made clear in Remark 2 after the proof of Theorem 1.

Before turning to the proof of Theorem 1, at first we derive a sufficient condition for optimality in \mathcal{U}_H . Given $u \in \mathcal{U}_H$ and $X = X^u$, we introduce the following backward stochastic differential equation in the pair of unknown (\mathcal{F}_t^H) -adapted processes $p = (p_t, t \in [0, T])$ and $\beta = (\beta_t, t \in [0, T])$:

$$dp_t = -a(t)p_t dt - q(t)X_t dt + \beta_t dM_t^H, \quad t \in [0, T]; \quad p_T = q_T X_T. \quad (10)$$

Lemma 1 Suppose that $u \in \mathcal{U}_H$ is such that $u = -(b/r)p$ where (p, β) is a pair of (\mathcal{F}_t^H) -adapted processes which satisfies equation (10). Then u minimizes J over \mathcal{U}_H .

Proof Given an arbitrary $u^* \in \mathcal{U}_H$, for which we use the notation $X_t^* = X_t^{u^*}$, we evaluate the difference $J(u^*) - J(u)$ between the corresponding cost and the cost for the announced candidate u to optimality over \mathcal{U}_H . Of course, we can write

$$J(u^*) - J(u) = \frac{1}{2}\mathbb{E}\left\{q_T[(X_T^*)^2 - X_T^2] + \int_0^T \{q(t)[(X_t^*)^2 - X_t^2] + r(t)[(u_t^*)^2 - u_t^2]\}dt\right\}.$$

Using the equality $(y^*)^2 - y^2 = (y^* - y)^2 + 2y(y^* - y)$ and exploiting the property $u = -(b/r)p$, it is readily seen that

$$J(u^*) - J(u) = \Delta_1 + \Delta_2,$$

where

$$\begin{aligned} \Delta_1 &= \frac{1}{2}\mathbb{E}\left\{q_T[X_T^* - X_T]^2 + \int_0^T \{q(t)[X_t^* - X_t]^2 + r(t)[u_t^* - u_t]^2\}dt\right\}, \\ \Delta_2 &= \mathbb{E}\left\{q_T X_T[X_T^* - X_T] + \int_0^T \{q(t)X_t[X_t^* - X_t] - b(t)p_t[u_t^* - u_t]\}dt\right\}. \end{aligned}$$

But, rewriting the quantity in the last integral as

$$(X_t^* - X_t)[q(t)X_t + a(t)p_t] - p_t[a(t)(X_t^* - X_t) + b(t)(u_t^* - u_t)],$$

and taking into account equations (1) and (10), we see that this integral can be written as

$$- \int_0^T (X_t^* - X_t)dp_t - \int_0^T p_t d(X_t^* - X_t) + \int_0^T (X_t^* - X_t)\beta_t dM_t^H.$$

Therefore, taking the expectation, since the stochastic integral part gives zero, we get that

$$\Delta_2 = \mathbb{E}\left\{q_T X_T [X_T^* - X_T] - \int_0^T (X_t^* - X_t)dp_t - \int_0^T p_t d(X_t^* - X_t)\right\}.$$

Now, integrating by parts, since $p_T = q_T X_T$ and $X_0^* - X_0 = 0$, it comes that $\Delta_2 = 0$ and finally $J(u^*) - J(u) = \Delta_1 \geq 0$. This of course means that u minimizes J over \mathcal{U}_H . \blacksquare

Now we show that the minimum value of J over \mathcal{U}_H is achieved uniquely and we identify the minimizer :

Lemma 2 *There exists a unique $u \in \mathcal{U}_H$ such that u can be represented as $u = -(b/r)p$ where (p, β) is a pair of (\mathcal{F}_t^H) -adapted processes which satisfies equation (10). Moreover for the corresponding pair (p, β) , the following representations hold :*

$$p_t = \pi(t)X_t + \int_0^t [\gamma(t, s) - \pi(t)K_H^c(t, s)]dM_s^H; \quad \beta_t = \bar{\gamma}(t), \quad (11)$$

where π, γ and $\bar{\gamma}$ are defined by equations (4), (1) and (3) respectively.

Proof At first, we prove the uniqueness. Suppose that u^1 and u^2 in \mathcal{U}_H both satisfy the required property, i.e., for $i = 1, 2$, we have $u^i = -(b/r)p^i$, where (p^i, β^i) is a pair satisfying equation (10) with $X^i = X^{u^i}$. Let us use the notations

$$\delta X = X^1 - X^2; \quad \delta p = p^1 - p^2; \quad \delta \beta = \beta^1 - \beta^2.$$

From equations (1) and (10), we have

$$\begin{aligned} d\delta X_t &= a(t)\delta X_t dt - \frac{b^2(t)}{r(t)}\delta p_t dt, \quad t \in [0, T]; \quad \delta X_0 = 0, \\ d\delta p_t &= -a(t)\delta p_t dt - q(t)\delta X_t dt + \delta \beta_t dM_t^H, \quad t \in [0, T], \quad \delta p_T = q_T \delta X_T. \end{aligned} \quad (12)$$

Applying the Itô formula to the product $\delta p_t \delta X_t$, we obtain immediately that

$$q_T [\delta X_T]^2 = - \int_0^T \{q(t)[\delta X_t]^2 + \frac{b^2(t)}{r(t)}[\delta p_t]^2\} dt + \int_0^T \delta X_t \delta \beta_t dM_t^H.$$

Thus, taking expectation, we get

$$\mathbb{E}_{q_T} \{ [\delta X_T]^2 + \int_0^T \{ q(t) [\delta X_t]^2 + \frac{b^2(t)}{r(t)} [\delta p_t]^2 \} dt \} = 0.$$

Consequently $\delta X_t \equiv 0$, $\delta p_t \equiv 0$ and hence also $\delta \beta_t \equiv 0$. This means in particular that $u^1 \equiv u^2$.

Now we turn to prove the existence. We take

$$u_t = -\frac{b(t)}{r(t)} p_t; \quad p_t = \pi(t) \tilde{X}_t + V_t, \quad (13)$$

where

$$d\tilde{X}_t = a(t) [\tilde{X}_t + \tilde{B}_t] dt - \frac{b^2(t)}{r(t)} [\pi(t) \tilde{X}_t + V_t] dt; \quad \tilde{X}_0 = x, \quad (14)$$

with

$$\tilde{B}_t = \int_0^t c(s) dB_s^H; \quad V_t = \int_0^t \gamma(t, s) dM_s^H. \quad (15)$$

Observe that actually, from (13)-(15), it appears that the process $X = \tilde{X} + \tilde{B}$ is nothing else but the state process X^u which corresponds to u by equation (1). Moreover, due to the representation (5), it is readily seen that we can rewrite p in terms of X in the form given in (11).

Now we check that p satisfies the final condition which is required in equation (10). Due to the representation (5) for $t = T$ and the final condition $\gamma(T, s) = q_T K_H^c(T, s)$ in equation (1), from definitions (15) we see that $V_T = q_T \tilde{B}_T$. Consequently, due the final condition $\pi(T) = q_T$ in equation (4), from definition (13) for $t = T$, it is clear that $p_T = q_T X_T$.

Finally, we show that the process p is a semimartingale and we identify its decomposition. Since $\gamma(\cdot, s)$ is differentiable, we see that V is a semimartingale and, due to the definition (3) of $\bar{\gamma}$, its stochastic differential is

$$dV_t = \left[\int_0^t \dot{\gamma}(t, s) dM_s^H \right] dt + \bar{\gamma}(t) dM_t^H.$$

Taking the expression of $\dot{\gamma}(\cdot, s)$ from the right-hand side of (1), this can be rewritten as

$$dV_t = \left[\int_0^t \{ -a(t) [\gamma(t, s) + K_H^c(t, s) \pi(t)] - q(t) K_H^c(t, s) + \frac{b^2(t)}{r(t)} \pi(t) \gamma(t, s) \} dM_s^H \right] dt + \bar{\gamma}(t) dM_t^H.$$

Hence, due to the definition (15) of V and \tilde{B} and taking into account the representation (5) of \tilde{B} , we get

$$dV_t = \{ -a(t) [V_t + \pi(t) \tilde{B}_t] - q(t) \tilde{B}_t + \frac{b^2(t)}{r(t)} \pi(t) V_t \} dt + \bar{\gamma}(t) dM_t^H. \quad (16)$$

Now, from the definition (13) of p , we have

$$dp_t = \dot{\pi}(t)\tilde{X}_t dt + \pi(t)d\tilde{X}_t + dV_t,$$

and, inserting (14) and (16), we can compute this stochastic differential. Using the equation (4) for π , it is easy to check that actually

$$dp_t = -a(t)p_t dt - q(t)[\tilde{X}_t + \tilde{B}_t]dt + \bar{\gamma}(t)dM_t^H.$$

This means exactly that dp_t is given by the right-hand side of equation (10) with $X_t = \tilde{X}_t + \tilde{B}_t$ and $\beta_t = \bar{\gamma}(t)$. Summarizing, we have checked that the pair (p, β) of (\mathcal{F}_t^H) -adapted processes defined in (11) satisfies equation (10) with the state process X corresponding to $u = -(b/r)p$. ■

Now we may turn to the proof of Theorem 1.

Proof of Theorem 1 - Here we use the same notations as in the proof of Lemma 2. At first we show that the optimal u in \mathcal{U}_H which has just been identified is actually the closed-loop control defined in (5)-(6) which then turns to be also optimal in \mathcal{U}_{ad} . We write $p_t = \pi(t)\tilde{X}_t + v_t$ where

$$v_t = V_t - \pi(t)\tilde{B}_t. \quad (17)$$

Using the Riccati equation (4) for π and the equation (16) for V to compute the stochastic differential

$$dv_t = dV_t - \dot{\pi}(t)\tilde{B}_t dt - \pi(t)c(t)dB_t^H,$$

it is readily seen that

$$v_t = \int_0^t [-a(s) + \frac{b^2(s)}{r(s)}\pi(s)]v_s ds + \int_0^t \bar{\gamma}(s)dM_s^H - \int_0^t \pi(s)c(s)dB_s^H.$$

But, due to the representation (7) of a stochastic integral with respect to M^H as an integral with respect to B^H , in terms of the function \bar{k} defined by (4), we can rewrite this as

$$v_t = \int_0^t [-a(s) + \frac{b^2(s)}{r(s)}\pi(s)]v_s ds + \int_0^t [\frac{\bar{k}(t, s)}{c(s)} - \pi(s)]c(s)dB_s^H.$$

Consequently, since due to (1) we have $c(s)dB_s^H = dX_s - [a(s)X_s + b(s)u_s]ds$, it means that the optimal pair (u, X) is governed by the system (5)-(6).

Finally we analyze the optimal cost. Let us recall the decomposition $X = \tilde{X} + \tilde{B}$ of the optimal state process and the representation $p = \pi\tilde{X} + V$ of the corresponding solution of equation (10). Using (10) and (14) and applying the formula of integration by parts to the

product $p_t \tilde{X}_t$, we can evaluate

$$\begin{aligned} p_T \tilde{X}_T &= p_0 \tilde{X}_0 + \int_0^T p_t d\tilde{X}_t + \int_0^T \tilde{X}_t dp_t \\ &= \pi(0)x^2 + \int_0^T \tilde{B}_t \{[a(t)\pi(t) + q(t)]\tilde{X}_t + a(t)V_t + q(t)\tilde{B}_t\} dt \\ &\quad + \int_0^T \bar{\gamma}(t)\tilde{X}_t dM_t^H - \int_0^T [q(t)X_t^2 + \frac{b^2(t)}{r(t)}p_t^2] dt. \end{aligned}$$

Of course when one takes the expectation in both sides the equality remains valid and actually the stochastic integral part in the right-hand side gives zero. Then, observing that

$$\begin{aligned} q_T X_T^2 &= q_T X_T \tilde{X}_T + q_T X_T \tilde{B}_T \\ &= p_T \tilde{X}_T + q_T [\tilde{X}_T \tilde{B}_T + \tilde{B}_T^2], \end{aligned}$$

and that for the optimal control u one has

$$\frac{b^2(t)}{r(t)} p_t^2 = r(t) u_t^2,$$

from the definition (2) of the cost function J , we get

$$\begin{aligned} 2J(u) &= \pi(0)x^2 + q_T [\mathbb{E}\tilde{X}_T \tilde{B}_T + \mathbb{E}\tilde{B}_T^2] \\ &\quad + \mathbb{E} \int_0^T \tilde{B}_t \{[a(t)\pi(t) + q(t)]\tilde{X}_t + a(t)V_t + q(t)\tilde{B}_t\} dt. \end{aligned} \tag{18}$$

Recall that $\tilde{B}_t = \int_0^t K_H^c(t, s) dM_s^H$ and $V_t = \int_0^t \gamma(t, s) dM_s^H$. Moreover, due to the equation (14), we can also write

$$\tilde{X}_t = \mathbb{E}\tilde{X}_t + \int_0^t f(t, s) dM_s^H.$$

where for $s \in [0, T]$, the function $f(\cdot, s) = (f(t, s), s \leq t \leq T)$ is the solution of the following differential equation in the variable t on $[s, T]$:

$$\dot{f}(\cdot, s) = \left(a - \frac{b^2}{r}\pi\right) f(\cdot, s) - \frac{b^2}{r}\gamma(\cdot, s) + aK_H^c(\cdot, s); \quad f(s, s) = 0. \tag{19}$$

Hence, from (18), we obtain that

$$\begin{aligned} 2J(u) &= \pi(0)x^2 + q_T \int_0^T \{f(T, s)K_H^c(T, s) + [K_H^c(T, s)]^2\} dw_s^H \\ &\quad + \int_0^T [a(t)\pi(t) + q(t)] \left\{ \int_0^t K_H^c(t, s) f(t, s) dw_s^H \right\} dt \\ &\quad + \int_0^T \left\{ a(t) \int_0^t K_H^c(t, s) \gamma(t, s) dw_s^H + q(t) \int_0^t [K_H^c(t, s)]^2 dw_s^H \right\} dt. \end{aligned}$$

Changing the order of integration in the double integrals of the right-hand side, we can rewrite

$$\begin{aligned} 2J(u) &= \pi(0)x^2 + \int_0^T \{q_\tau f(T, s)K_H^c(T, s) + \int_s^T g_1(t, s)dt\}dw_s^H \\ &+ \int_0^T \{q_\tau [K_H^c(T, s)]^2 + \int_s^T g_2(t, s)dt\}dw_s^H, \end{aligned} \quad (20)$$

where

$$g_1(t, s) = [a(t)\pi(t) + q(t)]K_H^c(t, s)f(t, s); \quad g_2(t, s) = a(t)K_H^c(t, s)\gamma(t, s) + q(t)[K_H^c(t, s)]^2.$$

But, using equations (1) and (19), it is easy to check that

$$q_\tau f(T, s)K_H^c(T, s) + \int_s^T g_1(t, s)dt = \int_s^T [a(t)K_H^c(t, s)\gamma(t, s) - \frac{b^2(t)}{r(t)}\gamma^2(t, s)]dt.$$

Inserting this into (20) and taking into account the expression (2) for the function $\dot{\lambda}(\cdot, s)$, we get

$$2J(u) = \pi(0)x^2 + \int_0^T \{q_\tau [K_H^c(T, s)]^2 - \int_s^T \dot{\lambda}(t, s)dt\}dw_s^H.$$

Therefore, since the final condition in (2) is $\lambda(T, s) = q_\tau [K_H^c(T, s)]^2$, we see that the following representation of the optimal cost holds :

$$J(u) = \frac{1}{2} \{ \pi(0)x^2 + \int_0^T \lambda(s, s)dw_s^H \}.$$

Finally, due to the notation $\bar{\lambda}(s) = \lambda(s, s)$ introduced in (3), this means that (7) holds. \blacksquare

Remark 2 *Let us justify the observation which is formulated in Remark 1. Actually, we can rewrite the component v_t defined by (17) in the previous proof as*

$$v_t = \int_0^t \mu(t, s)dM_s^H,$$

where

$$\mu(t, s) = \gamma(t, s) - \pi(t)K_H^c(t, s), \quad s \leq t.$$

It is readily seen that μ satisfies the following equation :

$$\frac{\partial \mu}{\partial t}(t, s) = -[a(t) - \frac{b^2(t)}{r(t)}\pi(t)]\mu(t, s) - \pi(t)\frac{\partial K_H^c}{\partial t}(t, s); \quad \mu(T, s) = 0.$$

Consequently, in terms of the function ϕ defined in (9), we have

$$\mu(t, s) = \int_t^T \phi(\tau, t)\pi(\tau)\frac{\partial K_H^c}{\partial \tau}(\tau, s)d\tau,$$

and

$$v_t = \int_t^T \phi(\tau, t) \pi(\tau) \left\{ \int_0^t \frac{\partial K_H^c}{\partial \tau}(\tau, s) dM_s^H \right\} d\tau.$$

But, due to the representation (5) of \tilde{B} , it is clear that for every $\tau \in [t, T]$, the predictor $\hat{B}_\tau^t = \mathbb{E}(\tilde{B}_\tau / X_s, s \leq t)$ of \tilde{B}_τ based on the observation of X on $[0, t]$ is given by

$$\hat{B}_\tau^t = \int_0^t K_H^c(\tau, s) dM_s^H; \quad \frac{d\hat{B}_\tau^t}{d\tau} = \int_0^t \frac{\partial K_H^c}{\partial \tau}(\tau, s) dM_s^H.$$

So, finally, we can represent v_t in the form

$$v_t = \int_t^T \phi(\tau, t) \pi(\tau) d\hat{B}_\tau^t.$$

This means exactly that the equality (8) claimed in Remark 1 is valid.

Concluding comments – Here we have solved the basic fractional type linear-quadratic Gaussian regulator problem when a complete observation is available. Actually, for a partially observable system where the observation is governed by a linear channel with an independent fractional Brownian noise, we can show that a certainty-equivalence principle holds, *i.e.*, the optimal control separates into two stages based on optimal filtering of the unobservable state and optimal control of the filtered state. This will be reported in a forthcoming paper.
