Prediction of Ideas Number During a Brainstorming Session

Hassan Ait Haddou · Guy Camilleri ·
Pascale Zaraté

Abstract In this paper, we present an approach allowing the prediction of ideas number during a brainstorming session. This prediction is based on two dynamic models of brainstorming, the non-cognitive and the cognitive models proposed by Brown and Paulus (Small Group Res 27(1):91–114, 1996). These models describe for each participant, the evolution of ideas number over time, and are formalized by differential equations. Through solution functions of these models, we propose to calculate the number of ideas of each participant on any time intervals and thus in the future (called prediction). To be able to compute solution functions, it is necessary to determine the parameters of these models. In our approach, we use optimization model for model parameters calculation in which solution functions are approximated by numerical methods. We developed two generic optimization models, one based on Euler's and the other on the fourth order Runge–Kutta's numerical methods for the solving of differential equations, and we apply them to the non-cognitive and respectively to the cognitive models. Through some feasibility tests, we show the adequacy of the proposed approach to our prediction context.

1 Introduction

The brainstorming technique is a very popular group technique for generating ideas. It is not surprising that this technique is often used in group decision making meetings (GDMM). Our aim is to integrate some specific support tools dedicated to facilitation activity into Group Decision Support Systems (GDSS) also called Group Support Systems (GSS). In our work we use the following definition of GDSS proposed by DeSanctis et al.: “A GDSS is a computer-based technology designed to help committees, project teams, and other small groups with activities such as problem identification and analysis, decision making, planning, creativity, conflict management, negotiation, and meeting management. GDSSs combine communication, information, and decision support technologies in an integrated environment.” p. 552 in DeSanctis et al. (2008). Many studies showed the advantage of using such systems in meetings in order to improve their effectiveness and efficiency (Nunamaker et al. 1991; de Vreede et al. 2003; Soller et al. 2005). Group facilitation is defined as a process in which a person who is acceptable to all members of the group intervenes to help improving the way it identifies and solves problems, and makes decisions (Schwarz 1994). Facilitation, on the other hand, is a dynamic process that involves managing relationships among people, tasks, and technology, as well as structuring tasks and contributing to the effective accomplishment of the meeting’s outcomes (den Hengst and Adkins 2007). Facilitation was for a long time recognized as a key success factor for meetings (Bostrom et al. 1993; Schwarz 1994; Hayne 1999). When GDSS tools are used or when e-meetings take place, the need to facilitate meetings is even more visible (Viller 1991; Bostrom et al. 1993; Macaulay and Alabdulkarim 2005).

Unfortunately, due to their specific skills, professional facilitators are mobile, scarce and expensive. Organizations have thus difficulty to maintain a stable in-house facilitation capability (den Hengst and Adkins 2007; Briggs et al. 2010). Therefore, it seems relevant to support this activity in order to make it more accessible to facilitators with less expertise while maintaining performance comparable to those obtained by a skilled facilitator and thus promote the adoption of GDSS in organizations.

Many works integrated elements of automated facilitation in GDSS tools (Limayem and DeSanctis 2000; Nunamaker et al. 2002; Wong and Aiken 2003; Macaulay and Alabdulkarim 2005; Adla et al. 2011). These works show the interest of automating some facilitation elements. Studies such as Wong and Aiken (2003), Limayem (2006) further demonstrate that the integration of automated facilitation in GDSS can be as effective as using the same tools with skilled-human facilitation. It also enhances a faithful appropriation of the technology.

Our purpose is to offer assistance to the facilitator in real time during meetings. For this, it is necessary to analyze the group activity, or even anticipate (predict) its evolution for supporting the facilitator in her/his decision to intervene (when) and her/his choice of interventions type (what). In this work, we focus on a particular group technique, the brainstorming. We limit here our work to provide, in an automatic way, a justified picture of the evolution of generated ideas for the current brainstorming activity in order to support the facilitator in her/his decision or choice of interventions. This information can be seen as a set of indications (or cues) on the dynamic of ideas generation (as in the work of Vivacqua et al. 2011).

In this paper, we developed an approach that gives some information (predictions) about the evolution of ideas number over time that would be generated by participants at a brainstorming session. Our prediction approach is based on the dynamic models of brainstorming, that were presented by Brown and Paulus (1996). These models are formalized by differential equations describing the evolution of ideas number over time for each participant.

The group technique of brainstorming has been proposed by Osborn (1957). The purpose of this technique is to improve productivity and creativity of the group (i.e. bringing many different and original ideas). It is based on the four following rules:

- *Criticism is ruled out.* To avoid trouble in the generation of ideas, participants at a brainstorming session should not criticize. This rule follows a central principle of brainstorming: the “deferment of judgment”.
- *Freewheeling is welcomed.* As it is not allowed to criticize, unusual and even wild ideas are possible and desired.
- *Quantity is wanted.* One purpose of brainstorming is to gather up a maximum number of ideas, assuming the greater number of ideas, higher is the probability to find successful ones.
- *Combination and improvement are sought.* Participants are encouraged to use the ideas of others by combining or improving them.

In order to take the full advantage of brainstorming, Osborn mentioned that the previous rules were not sufficient. In addition, he provided some suggestions and recommendations on the training and the management of brainstorming meetings (facilitation, participants training, topic nature, group composition, etc).

Osborn claimed that a real group using brainstorming technique to generate ideas will be more effective than individuals alone. He indicated that in a study, this technique generated 44% more useful ideas than individuals working alone. However, a large number of experimental studies contradict this claim by noting that interactive brainstorming groups tended to produce less than nominal groups (groups of similar size working alone) (Diehl and Stroebe 1987; Mullen et al. 1991).

Many researches have attempted to find the reasons of the “failure” of interactive brainstorming (called productivity loss). They identified four main reasons:

- *Evaluation apprehension* (Camacho and Paulus 1995; Mullen et al. 1991). Participants may feel a fear of negative evaluations from others. In this case, they may be led to not express their more original ideas (self-censorship).
- *Social loafing or Free riding* (Borgatta and Bales 1953; Diehl and Stroebe 1987; Karau and Williams 1993; Paulus and Dzindolet 1993). Social loafing is a loss of motivation and effort caused by the presence of others. Free riding occurs when an individual considers that his contribution is not necessary to the group success.
- *Production blocking* (Diehl and Stroebe 1991; Nijstad et al. 2003). When someone speaks, other participants are usually blocked, bringing about a risk of ideas forgetfulness.
- *Matching.* Participants in brainstorming session tend to want to produce as others (in the same order of magnitude). This behaviour seems to result from a comparison in terms of performance between individuals within a group. Brown and Paulus (1996) noted that matching may occur in different contexts in both directions,

towards participants who are most productive when there is a climate of competition between group members (Upward matching Paulus and Dzindolet 1993), or conversely towards participants producing the least if motivation of the group is quite weak (Downward matching Borgatta and Bales 1953; Camacho and Paulus 1995; Karau and Williams 1993).

In order to improve the effectiveness of brainstorming meetings, many studies have attempted to reduce the loss of productivity. Camacho and Paulus (1995) formed groups with low anxious members; Oxley et al. (1996) showed the importance of trained facilitators which provide a control over free-riding; the use of electronic brainstorming for eliminating the blocking (Diehl and Stroebe 1991; Nijstad et al. 2003); anonymous electronic brainstorming in order to reduce evaluation apprehension (DeRosa et al. 2007); the addition of breaks in meetings and promoting divergent thinking (Brown and Paulus 2002; Coskun 2005), etc. Many findings of these studies seem to agree with the suggestions and the recommendations presented by Osborn (cf. the critical review of Isaksen (1998) emphasizing the importance of these suggestions and recommendations in brainstorming studies).

From works on productivity loss, Brown and Paulus (1996) proposed a modeling of ideas generation process in brainstorming. This modeling describes for each participant the evolution of ideas number over time according to the productions of other participants. It explicitly incorporates three social factors: the blocking, the matching (described above) and the decay. The decay factor is useful to decrease ideas number over time (Nijstad et al. 2003). In this modeling, the factors of evaluation apprehension and free riding are represented implicitly through values of several parameters. In this work, Brown and Paulus presented two models, a non-cognitive and a cognitive model. Of course, these models are a simplification of the ideas generation process, but are in line with findings of various studies on productivity loss. One interest of these models is to provide a clear and relatively precise description of the interdependence existing between participants' productions. In addition, they allow differentiating the impact of three social factors in ideas production. The initial objective of this modeling is to provide a framework for the development and the assessment of theoretical assumptions.

We believe that the model developed by Brown and Paulus can be adapted to our context of prediction. Indeed, assuming that the proposed dynamic models are completely determined (that is all parameters are valued), they offer for each participant an accurate description of ideas number represented in the form of mathematical function. By knowing this function of ideas number over time on its definition domain $D = [0, +\infty[$, it is possible for each participant to calculate on any subintervals of D the ideas number and therefore, to compute an extrapolation of ideas number in the future (which we call prediction).

Coskun and Yilmaz (2009) improved the models proposed by Brown and Paulus by adding physical constraints (such as the rate of ideas is always positive) to make these models more realistic and complete. In addition, they modified them to deal with two situations: the sequential situation where the problem is decomposed into sub-problems and each sub-problem is presented one after other to the group (called sequential brainstorming), and the situation of brainwriting. They also studied the impact of

the instruction of ideas memorization on brainstormers. The aim of their work is to develop new models adapted to the previous situations (formalized by impulsive differential equations) and to show through experiments that these two models well fit to observations. In order to do so, they chose some values for model parameters so that models are close to their experiments.

Our approach towards dynamic models use is quite different from the above two studies. We determine ideas number from measurements of production duration of participants' ideas¹ in real-time (that is ongoing the brainstorming session). For this, we must be able to compute relatively quickly the model parameters from ideas already expressed by participants. This context has motivated us to develop our approach for determining parameters of dynamic models presented in this work.

In order to make this approach directly usable (computable), we assume that each contribution of a participant matches to one and only one idea. This assumption may appear very strong implying the addition of the following rule "one idea per intervention", and the need to strictly ensure compliance with brainstorming rules. However, from preliminary experiments, it seems that the proposed approach remains useful for free ideation sessions. Nevertheless, more investigations must be achieved on this point.

First, we will present an overview of the proposed approach. In the second part, we will deal with the non-cognitive model. Our approach of parameters calculation is based on an optimization model. We will present a generic optimization model² which will be applied to the non-cognitive model. Feasibility tests will show the adequacy of the proposed approach to our prediction context.

In the third part, the cognitive model will be presented. The optimization model developed for the non-cognitive can not be directly applied to the cognitive model. To cope with this problem, we will propose a more accurate (but more complex) new generic optimization model. This new problem will be adapted to the cognitive model, and as for the non-cognitive model, its feasibility will be tested. We will show that this new optimization model is well adapted to groups of small size, but may requires further developments for larger groups.

2 Approach Overview

The overall proposed process in this paper is schematically summarized in the Fig. 1. The box items represent problems and the oval-boxes the used approaches. The goal of this process is to determine time evolution functions of ideas production rate for each participant (box 1) from dynamic models (Ordinary Differential Equations ODE). In order to achieve this objective, two numerical methods (Euler and Runge–Kutta fourth RK4) are used (2). However, to be able to apply these methods, models parameters have to be known (3). A least-square optimization is used for computing these model parameters (4). From now, dynamic models and their parameters are known and

¹ We intend to measure the duration of ideas production by using microphones.

² We believe that this generic problem could be useful in many other situations.

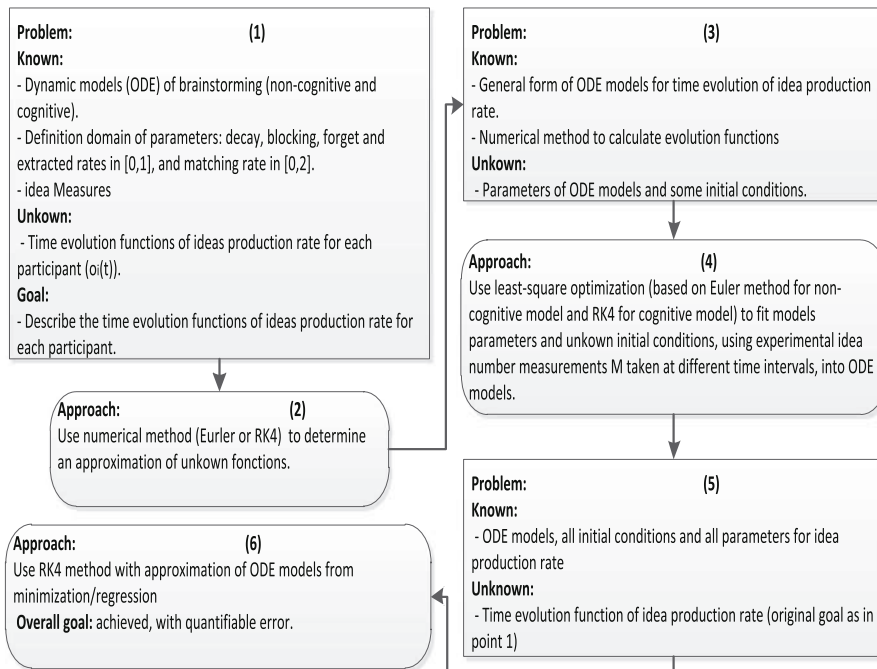

Fig. 1 Process overview

solution functions can be computed (5). Solution functions and a quantifiable error are then determined by using the Runge–Kutta fourth (6).

3 Non-Cognitive Model of Brainstorming

In this part, the non-cognitive model is presented. We will begin with a description of the mathematical model (modified by Coskun and Yimaz). Then a generic approach, using an optimization model to determine the parameters of dynamic models from measurements, will be presented. We will apply this generic optimization model to the non-cognitive model of brainstorming. In order to test the feasibility of our approach, we will use artificial tests. This part will end with a discussion on tests, advantages and disadvantages of the proposed approach.

3.1 Mathematical Model

The non-cognitive model is the simplest model presented by Brown and Paulus (1996). This model is based on the assumption that a participant's rate of idea production depends on the following three factors (see Brown and Paulus 1996):

1. *Output decay*: Any given participant will eventually run out of ideas. This factor serves to decrease productivity over time.

2. *Blocking*: A participant's productivity will decrease as a function of total group output.
3. *Matching*: Participants adjust their productivity rate to more closely match the average group rate. This factor decreases a participant's productivity if it is higher than the group average and increases a participant's productivity if it is lower than the group average.

This model expresses for each participant, the variation of ideas rate as a weighted sum of decay, blocking and matching factors.

For a group of n individuals ($i \in \llbracket 1, n \rrbracket$), the non-cognitive model is formalized by the following system of differential equations:

$$\frac{do_i(t)}{dt} = -a_i o_i(t) - b_i \sum_{j \neq i} o_j(t) + m_i \left[\frac{1}{n-1} \sum_{j \neq i} o_j(t) - o_i(t) \right] \text{ with } o_i(t) \geq 0$$

and $t \in [0, +\infty[$

where $o_i(t)$ is the ideas rate (ideas number per time unit) generated by the participant i , a_i the decay rate, b_i the sensitivity to blocking, m_i the tendency to match. Note that the rates a_i , b_i and m_i represent the impacts of decay, blocking and matching factors on the ideas rate of a participant i . This impact is assumed to be constant over time during the whole session (that is a_i , b_i and m_i are constant). The blocking is represented by b_i times the sum of others' productions. The matching is estimated by the distance between productions of an individual and the average of others' productions. Following Coskun and Yilmaz (2009), we add the constraint $o_i(t) \geq 0$ to model the fact that ideas rate is always positive or null. A possible effect of this constraint is to break the linearity of the differential equations.

This model states that the ideas rate decreases at the rate a_i with respect to its value, at the rate b_i with respect to the sum of other's rates, and depending on cases decreases (negative value) at the rate m_i if its value is higher than the average of others' rates (Downward matching) or increases (positive value) at the rate m_i if its value is lower than the average (Upward matching).

For example, for a group of three persons, the cognitive model is:

$$\begin{cases} \frac{do_1(t)}{dt} = -a_1 o_1(t) - b_1(o_2(t) + o_3(t)) + m_1 \left[\frac{1}{2}(o_2(t) + o_3(t)) - o_1(t) \right] \\ \text{with } o_1(t) \geq 0, \\ \frac{do_2(t)}{dt} = -a_2 o_2(t) - b_2(o_1(t) + o_3(t)) + m_2 \left[\frac{1}{2}(o_1(t) + o_3(t)) - o_2(t) \right] \\ \text{with } o_2(t) \geq 0, \\ \frac{do_3(t)}{dt} = -a_3 o_3(t) - b_3(o_1(t) + o_2(t)) + m_3 \left[\frac{1}{2}(o_1(t) + o_2(t)) - o_3(t) \right] \\ \text{with } o_3(t) \geq 0 \end{cases}$$

The Fig. 2 illustrates the cognitive model for a group of three persons by drawing the ideas rate over time generated by each participant. In this example, the following parameters vectors have been used: $p_1 = (3.337, 0.044, 0.140, 0.222)$, $p_2 = (3.467, 0.005, 0.022, 0.256)$ and $p_3 = (4.036, 0.120, 0.077, 0.189)$ where

Fig. 2 Cognitive model for a group of three members (one curve by member)

$p_i = (o_i(0), a_i, b_i, m_i)$ is the parameters vector for participant i with $o_i(0)$ the initial rate of ideas, a_i , b_i and m_i are respectively decay, blocking and matching rates.

The solutions of this system have been calculated by using the numerical method of Runge–Kutta order four³. In most cases, it is not possible to have an analytical solution due to equations complexity. Therefore, numerical methods can be used to calculate an approximation of solution functions.

3.2 Euler Based Generic Optimization Model for Parameters Calculation

This model is useful in a prediction context, which is used to calculate automatically model parameters only from measurements of production duration during the session. A natural way for parameters computing would be to start from analytical solution functions and through them to generate equations corresponding to measurements. Unfortunately, in every case analytical solutions are not necessarily known. In our approach, we propose to use optimization formulation for the calculation of the model parameters calculation in which solution functions are approximated by numerical methods.

For the non-cognitive model, we will use the Euler’s method (Ait-Haddou et al. 2010). The Euler’s method is a first-order numerical procedure for solving ordinary differential equations with a given initial value. This method determines a linear approximation of the solution functions of first order differential equations.

Let us consider the following first order differential equation $\frac{dy}{dx} = f(x, y)$ with initial value $y(a) = y_0$ where $f(x,y)$ is a known function define on an interval $I = [a,b]$.

³ With a step of 1E-3.

Let $h = \frac{b-a}{n}$ be a real positive number where n is the number of considered points. The real h is called “step” and it is the step sizes between the points x_0, x_1, \dots, x_n .

The Euler’s method considers two sequences of real numbers x_i and y_i for all $i \in \llbracket 0, n-1 \rrbracket$ such that $x_{i+1} = x_i + h$ and $y_{i+1} = y_i + hf(x_i, y_i)$ with values in initial condition are respectively $x_0 = a$ and $y_0 = y(a)$. The linear approximation function of $y(x)$ on I is given by $\phi(x) = f(x_i, y_i)x + y_i - f(x_i, y_i)x_i$ for all $x \in [x_i, x_{i+1}]$ and $\phi(x_0) = y_0$.

In this work, we plan to determine the parameters of a system of differential equations obtained from measurements.

These measurements represent the number of ideas on a given interval $[a,b]$ which is equal to $\int_a^b y(t)dt$. To find the parameters of dynamic models we propose the following optimization model:

Objective function:	$Min \left(\alpha \sum_{i=1}^m e_i^2 + f_{dm}(p) \right)$ where m is the number of measures,
Constraints:	$y_{i+1} = y_i + (x_{i+1} - x_i)f(x_i, y_i, p)$ for all $i \in \llbracket 0, m-1 \rrbracket$, $S_{i+1} = \frac{(x_{i+1}-x_i)(y_i+y_{i+1})}{2}$ for all $i \in \llbracket 0, m-1 \rrbracket$, $M_{a,b,i} = \sum_{j=ord(a)}^{ord(b)} S_j + e_i$ for all $i \in \llbracket 1, m \rrbracket$,
Data:	$M_{a,b,i}$ is the i th measure on $[a, b]$, x_i sorted abscissa of considered points, α errors weight, $ord(u)$ returns the position of u in x ,
Decision Variables:	f differential equation $\frac{dy}{dx} = f(x, y, p)$ of the model, p parameters in differential equation, y_i points determined by the Euler’s linear approximation, S_i trapezoid area with height $x_{i+1} - x_i$, f_{dm} objective function related to differential equation, e_i error of the i th measure.

In this optimization model, the objective function is divided in two parts. As Euler’s method computes an approximation of solution functions, an error is inevitably present. The first part of objective function concerns the minimization of this error. The second part is specific to the dynamic model considered. In constraints, y_i are Euler’s points, S_i correspond to surfaces calculated with Euler’s points. As Euler’s method computes a linear approximation of solution functions; integration of these approximations corresponds to the calculation of trapezoid surfaces. In this problem, measures can overlap, therefore for one measure on $[a,b]$, it is possible that several points would be calculated, in this case the measure corresponding to $\int_a^b y(t)dt$ is equal to the sum of trapezoid surfaces defined from these points. At each measure, an error is integrated for the approximation error but can also be used to introduce measurement errors.

3.3 Optimization Model for Parameters Calculation of Non-Cognitive Model

In order to calculate parameters of the cognitive model, we apply the generic optimization model previously presented. In our prediction context, solving time is important to be able to use the optimization model during brainstorming sessions. Therefore, it is necessary to find a good compromise between solving time and precision. For this, we chose as Euler's points the starting and the ending points of measure's intervals. In this way, we limit the number of decision variables such that x_i , y_i and S_i to the minimum entailing a simplification of the optimization model.

The optimization model for the non-cognitive model can be expressed as follow:

Objective function:	(1) $Min \left(\frac{4}{7} \sum_{k=1}^n \sum_{i=1}^m e_{i,k}^2 + f_{dm}(a_k, b_k, m_k) \right)$ where m is the number of measures, (2) $f_{dm}(a_k, b_k, m_k) = \frac{1}{7} \sum_{k=1}^n (a_k - 0.0235)^2 + \frac{1}{7} \sum_{k=1}^n (b_k - 0.035)^2 + \frac{1}{7} \sum_{k=1}^n (m_k - 0.2)^2$ with n the group size and $k \in [1, n]$,
Constraints:	(3) $y_{i+1,k} = o_{i,k} + (t_{i+1} - t_i) f_{i,k}$ for all $i \in \llbracket 0, m-1 \rrbracket$ and $k \in \llbracket 1, n \rrbracket$, (4) $f_{i,k} = -a_k o_{i,k} - b_k \sum_{l \neq k}^n o_{i,l} + m_k \left[\frac{1}{n-1} \sum_{l \neq k}^n o_{i,l} - o_{i,k} \right]$ for all $i \in \llbracket 0, m \rrbracket$ and $k \in \llbracket 1, n \rrbracket$, (5) $o_{i,k} = y_{i,k}$ if $y_{i,k} \geq 0$, 0 else, for all $i \in \llbracket 1, m \rrbracket$ and $k \in \llbracket 1, n \rrbracket$, (6) $S_{i+1,k} = \frac{(t_{i+1} - t_i)(o_{i,k} + o_{i+1,k})}{2}$ for all $i \in \llbracket 0, m-1 \rrbracket$ and $k \in \llbracket 1, n \rrbracket$, (7) $M_{a,b,i,k} = \sum_{j=ord(a)}^{ord(b)} S_{j,k} + e_{i,k}$ if $M_{a,b,i,k} = 1$, for all $i \in \llbracket 1, m \rrbracket$ and $k \in \llbracket 1, n \rrbracket$, (8) $\sum_{j=ord(b)}^m S_{j,k} + e_{m,k} < 1$ if $M_{a,b,k} = 1$ and $M_{b,tm,k} < 1$, with $k \in \llbracket 1, n \rrbracket$, (9) $a_k, b_k \in [0, 1]$ and $m_k \in [0, 2]$, (10) $o_{i,k} \geq 0$ for all $i \in \llbracket 0, m \rrbracket$ and $k \in \llbracket 1, n \rrbracket$, (11) $e_{i,k} \in [-0.4, 0.4]$ for all $i \in \llbracket 1, m \rrbracket$ and $k \in \llbracket 1, n \rrbracket$,
Data:	$M_{a,b,i,k}$ is the i th measure of the participant k on $[a, b]$, t_i boundary measures in chronological order, $ord(x)$ returns the position of x in t ,
Decision Variables:	a_k, b_k and m_k model's parameters of participant k , $y_{i,k}$ the i th Euler's points for participant k , $o_{i,k}$ the i th ideas rate of participant k , $f_{i,k}$ differential equations of the model, $f_{dm}(a_k, b_k, m_k)$ dynamic model part of objective function, $S_{i,k}$ i th trapezoid surface for participant k , $e_{i,k}$ error of the i th measure for participant k .

The model part of objective function (2) represents a square distance between social factors and their reference values. Reference values chose in this problem are those that have been established by Coskun and Yilmaz (2009) in their experimentations. The whole objective function is a weighted sum of square distances to reference values.

Fig. 3 Non-cognitive model with initial and found by optimization parameters

We consider that minimizing as possible errors is more important than factors' values close to their reference values, because more errors are low more measures follow the differential equations (model). This preference is translated in weights where errors have a weight of $\frac{4}{7}$ and social factors a weight of $\frac{1}{7}$.

The constraint (3) define Euler's points according to differential equations presents in (4). Ideas rates follow Euler's points if they are positive or are set to zero otherwise (5), this constraint comes from the Coskun's and Yilmaz's modelling. We chose to process every idea one by one, therefore our measures are define to one idea (7). When a brainstorming session finishes all participants could not have enough time to generate one more idea, this situation is formalized in the constraint (8).

For example in Fig. 3, full lines represent the initial ideas rates over time (in minutes) for a group of three participants. The initial model is graphed using Runge–Kutta's four order method with the same parameters as before (that is $p_1 = (3.337, 0.044, 0.140, 0.222)$, $p_2 = (3.467, 0.005, 0.022, 0.256)$ and $p_3 = (4.036, 0.120, 0.077, 0.189)$). From these initial solutions, measures are computed by determining for each participant, all consecutive intervals $[a, b] \subseteq [0, 20]$ from 0 such as $\int_a^b o_i(t)dt = 1$. We then use the non-cognitive optimization model only with these measures to calculate new parameters. The new parameters calculated in this way are $\hat{p}_1 = (3.329, 0.114, 0.100, 0.148)$, $\hat{p}_2 = (3.551, 0.024, 0.026, 0.200)$ and $\hat{p}_3 = (4.013, 0.121, 0.071, 0.200)$ where $\hat{p}_i = (\hat{o}_i(0), \hat{a}_i, \hat{b}_i, \hat{m}_i)$ with $\hat{o}_i(0)$ the initial rate of ideas, $\hat{a}_i, \hat{b}_i, \hat{m}_i$ are respectively decay, blocking and matching rates obtained with the optimization model. In the Fig. 3, the solution functions $\hat{o}_1(t)$, $\hat{o}_2(t)$ and $\hat{o}_3(t)$ computed with Runge–Kutta fourth are represented by dotted lines. In this example, these new parameters \hat{p}_1 , \hat{p}_2 and \hat{p}_3 provide a quite good approximation.

3.4 Feasibility Tests

Our feasibility tests follow roughly the procedure above:

1. Parameters P are drawn at random,
2. solution functions $o_i(t)$ are computed by Runge–Kutta fourth method (precision of $1E-3$),
3. from these solution functions, measures M_j are extracted on all consecutive intervals $[a, b]$ from 0 such as $\int_a^b o_i(t)dt = 1$ with $j \in \llbracket 1, 4 \rrbracket$ and $b \leq b_j$,
4. the optimizer is launched with M_j in the non-cognitive problem previously described,
5. new parameters \hat{P}_j are then calculated by the optimizer,
6. solution functions $\hat{o}_i(t)$ from \hat{P}_j are computed by Runge–Kutta fourth method (precision of $1E-3$),
7. Errors $e_{j,l}$ are determined with $l \in \llbracket 1, 4 \rrbracket$ and $l \geq j$.

More precisely, four measure sets M_j are respectively extracted on intervals $[0, 5]$, $[0, 10]$, $[0, 15]$ and $[0, 20]$ (3). These measure sets simulate respectively the first 5 min, the first 10 min, the first 15 min and the whole session. For each measure set, model parameters and solution functions are computed (4 and 5).

Our objective is to predict the ideas number in the future. Therefore, we do not calculate only an error on M_j but also on next intervals. For example, for M_1 (interval $[0, 5]$), four errors are calculated on intervals $[0, 5]$, $[0, 10]$, $[0, 15]$ and $[0, 20]$. In this way, errors give some information about the solution functions accuracy after the last measure (in the future).

We chose the following error calculus on interval $[a, b]$:

$e = \sum_{i=1}^n \left| \int_a^b (\hat{o}_i(t) - o_i(t))dt \right|$, corresponding to the difference between the initial number of ideas and the optimized number of ideas for the group.

In our test, we vary the group size from 2 to 10. For each size, the test procedure is repeated five times from which the mean, the variance, the minimum and the maximum of errors are calculated.

An extract of our tests results are presented in the Table 1. In the first column, the group size is pointed out, the total solving time is given in the second column and, in the other columns, errors are calculated on considered intervals. Rows contain intervals on which measures have been extracted. These tests have been performed by GAMS/CONOPT3 non-linear optimizer⁴. We used default configuration options of CONOPT3. The total solving time integrates the GAMS's compilation time and the CONOPT3's optimization time.

In the Table 1, solving time is described in the following format “minutes:seconds”. On average, more the group size is important more the problem is difficult to solve. This tendency can be observed through the solving time. The solving time remains reasonable; its maximum value is 16 s for ten persons. As we can see, errors are not too different between measure intervals and extrapolated intervals. This seems to confirm the adequacy of the proposed approach to the prediction of the ideas number in the

⁴ On a PC computer (Pentium Dual-Core E5200 2.5GHZ and 4 GO RAM) with Windows XP operating system.

future. Let us note that our error calculus is a cumulative calculus, that is for two participants if individual errors were 0.5 then the group error would be 1. Depending to the way of production duration is assessed; this error can overestimate (equals to 0) or underestimate (equals to 2) the real value. We intend to assess the production interval $[a, b]$ by considering that a is the instant of the end of the last production and, b is the instant of the end of the current production. In most cases, the expression time (speech time) is short in the interval $[a, b]$, our error calculus will thus overestimate the real e .

3.5 Discussion

Our approach presented earlier seems appropriate to predict ideas number using differential equations based on models. We believe that this approach can be useful in several other situations if we adapt the generic optimization model.

Some important advantages of this approach are:

- model parameters can be calculated only with measures through the optimization model,
- the solving time of the optimization model can be fast,
- it can be used when the solution functions of differential equations are not known, or if they were known when the integral functions remain unknown,
- it processes cases where measures overlap.

Of course, this approach shows also some disadvantages:

- The numerical method provides an approximation of solution functions,
- the optimization model requires an hand configuratio by definin the precision (x_i points), the model part of the objective function and errors range.
- The Euler's method is very sensitive to the function variations inside define steps ($x_{i+1} - x_i$). As the slope of the straight line is calculated only at the start of steps (x_i), if the slope strongly varies (that is slope in others points is very different), then the Euler's linear approximation could be really wrong.

Our feasibility test confirm that the presented optimization model could be used to determine parameters of the non-cognitive model during a brainstorming session only with the knowledge of ideas production duration. Moreover, solution functions determined with these computed parameters allow the prediction of ideas number in the future (after the expression of the last idea).

4 Cognitive Model of Brainstorming

The cognitive model used in this part is more complex than the non-cognitive model (see [Brown and Paulus 1996](#)). We will show that this cognitive model is out of the applicability scope of the previous generic optimization model. A more accurate new model will be proposed to solve problems posed by the cognitive model. This general optimization model will be adapted to the cognitive model of brainstorming, and we will test its feasibility on artificia tests. As for the non-cognitive model, we will discuss the tests, advantages and disadvantages of this new optimization model.

4.1 Mathematical Model

In the cognitive model, three cognitive processes are introduced: idea generation, idea memory and idea output. This model assumes that a participant generates ideas (generation process) and stores them in short-term memory (memorization process) and then eventually extracts some of them from its short-term memory to express them (output process).

For each participant i of a group of size n , this model is represented by the following three equations:

$$\frac{dg_i(t)}{dt} = -a_i g_i(t) - b_i \sum_{j \neq i} o_j(t)$$

$$\frac{ds_i(t)}{dt} = -c_i s_i(t) + g_i(t) - o_i(t) \text{ with } g_i(t) \geq 0, 0 \leq s_i(t) \leq K, o_i(t) \geq 0$$

and $t \in [0, +\infty[$

$$\frac{do_i(t)}{dt} = -d_i o_i(t) + r_i s_i(t) - f_i \sum_{j \neq i} o_j(t) + m_i \left[\frac{1}{n-1} \sum_{j \neq i} o_j(t) - o_i(t) \right]$$

where $g_i(t)$ describes the rate of generated ideas by the participant i over time. it decays at the rate a_i . This model considers the produced ideas (outputs) of other participants block the ideas rate of i at the rate b_i . $s_i(t)$ is the number of ideas in the short-term memory, c_i is the forget rate. As for the non-cognitive model, $o_i(t)$ is the ideas rate which decay at the rate d_i ; f_i and m_i are respectively the blocking and the matching influences. The additional term r_i represents the rate of ideas extracted from the memory. In this modelling, ideas come from the idea generation process, and then are stored in memory (memorization process) and then are outputted (output process). Thus, at the session beginning ($t = 0$), the generation and memorization rates are equal to zero ($o_i(0) = s_i(0) = 0$).

As Coskun and Yilmaz (2009), to be more realistic, some physical constraints have been added. These constraints state that the rate of generated ideas ($g_i(t)$), the rate of ideas in memory ($s_i(t)$) and the rate of expressed ideas ($o_i(t)$) must be positive or null. Moreover, the memory capacity is not considered infinite but is limited to the constant value K .

The impact of blocking factor on ideas number is formalized in the same manner as in non-cognitive model. Blocking influence both generation and output processes. In the generation process, ideas expressed by others are assumed to captivate a bit of attention of a participant and therefore may have the effect of inhibiting its train of thought. When someone speaks, usually the others will not have too much the desire to speak at the same time; this behavior is formalized by the blocking factor in the output stage. On the other hand, the matching only affects the output process and shares the same mathematical representation with the non-cognitive model.

For example, in the Fig. 4, the cognitive model is plotted for a group of two members. In this figure parameters vectors used are $p_1 = (2.750, 0, 0, 0.024, 0.035, 0.200, 0.900, 0.024, 0.024, 0.035)$ and $p_2 = (2.250, 0, 0, 0.024, 0.035, 0.200, 0.900, 0.024, 0.024, 0.035)$ where $p_i = (g_i(0), s_i(0), o_i(0), a_i, b_i, c_i, d_i, r_i, f_i, m_i)$ are the parameters vector of participant i and $g_i(0)$ is the initial rate of ideas number, a_i the decay rate and b_i the blocking rate for the idea generation process; $s_i(0)$ always equal to zero is the initial rate of ideas number in memory and c_i the forget rate; $o_i(0)$ also equal to zero is the initial rate of ideas number expressed, d_i, r_i, f_i and m_i are respectively the decay, extracted, blocking and matching rates of the output process.

The numerical Runge–Kutta method fourth order⁵ has been used to compute solution functions of each cognitive process. As for the non-cognitive model, due to model complexity, it is not always possible to find solution functions in the form of analytical functions, then we will use numerical methods to approximate the above solution functions.

⁵ With a step of 1E-3.

Fig. 4 Example of cognitive model with a group of two members. **a** Generation process. **b** Generation process. **c** Output process

4.2 Runge–Kutta Based Generic Optimization Model for Parameters Calculation

Unfortunately, in most cases, the previous generic optimization model based on Euler’s method can not be used for the cognitive model. To illustrate this problem, let us consider the cognitive model presented in Fig. 5a. This model is the same as in Fig. 4 (same parameters vectors). Solution functions (full lines) are calculated by Runge–Kutta’s fourth method with a step of $1E-3$. From these functions, measure intervals $[a, b]$ corresponding to a surface of one ($\int_a^b o_i(t)dt = 1$) are extracted. As in our previous optimization model, Euler’s method is applied on these measure intervals, thereby defining our Euler’s solution functions (dotted lines). As we can see in the Fig. 5a, the approximation caused by Euler’s functions is too bad and will result in an infeasible optimization problem.

In this dynamic model, the variation of ideas rate inside measure intervals can be important. In this case, the Euler’s method is not suitable (see the disadvantages previously discussed). One way to address this problem would be to increase the precision by decreasing the step. However, this approach entails an increase number of decision variables resulting in a more complex optimization model that will increase also the solving time. In the example of Fig. 5, a step of $0.5E-1$ can be used, nevertheless

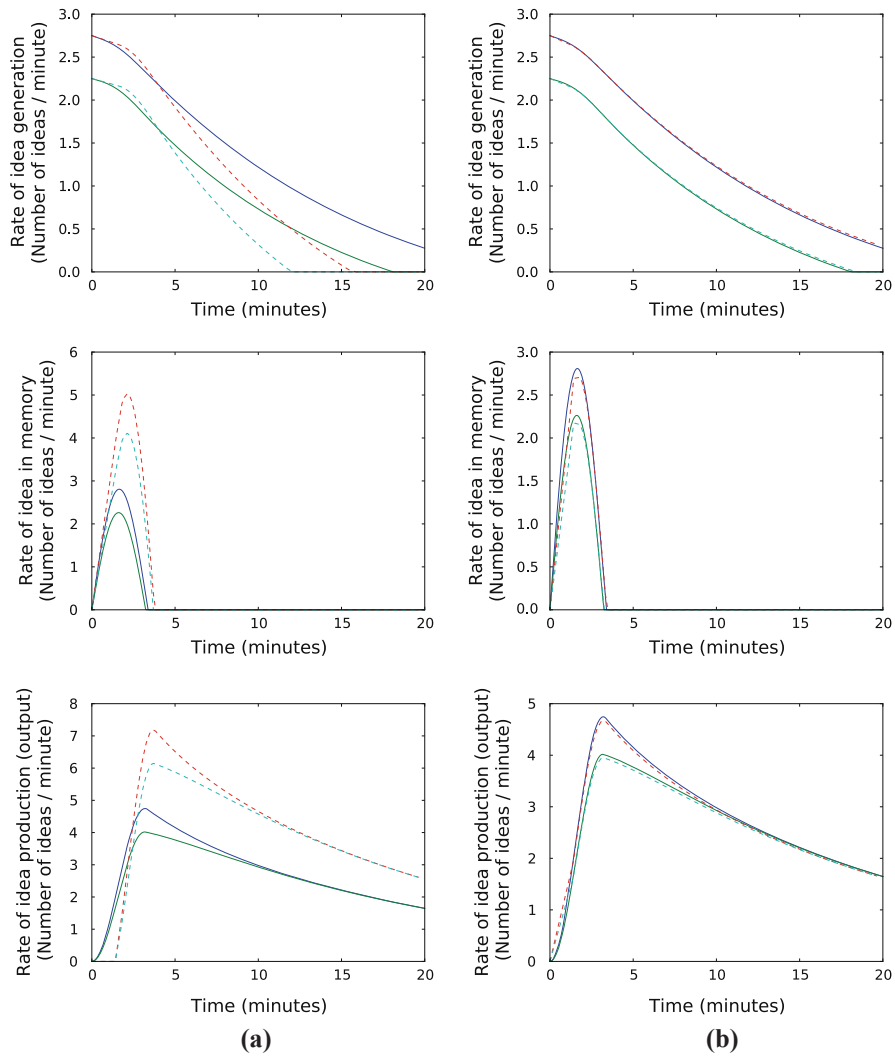

Fig. 5 Example of cognitive model with a group of two members. **a** Euler's method on measure intervals. **b** Runge-Kutta's fourth method on measure intervals

this would generate 73% more x_i variables. Another way to deal with this problem would be to change the numerical method to a more precise. We chose this second approach by using the Runge-Kutta's fourth numerical method for solving first order ordinary differential equations. As we can see in Fig. 5b, in the previous example, the Runge-kutta's method was applied to measure intervals and provides a satisfactory approximation.

The fourth order Runge-Kutta's method as Euler's method determines a linear approximation of solution functions of first order differential equations. Let us consider the first order differential equation $\frac{dy}{dx} = f(x, y)$ with initial value $y(a) = y_0$

and $f(x,y)$ is a known function define on an interval $I = [a, b]$. Let $h = \frac{b-a}{n}$ be a real positive number where n is the number of considered points. The real h is called “step” and it is the step sizes between the points x_0, x_1, \dots, x_n .

The fourth order Runge–Kutta’s method considers two sequences of real numbers x_i and y_i for all $i \in \llbracket 0, n - 1 \rrbracket$ such that $x_{i+1} = x_i + h$ and $y_{i+1} = y_i + hK_i$ with $K_i = \frac{k_i^1 + 2k_i^2 + 2k_i^3 + k_i^4}{6}$ where:

$$\begin{aligned} k_i^1 &= f(x_i, y_i), & k_i^1 & \text{ is the slope at } x_i \text{ (interval beginning),} \\ k_i^2 &= f\left(x_i + \frac{h}{2}, y_i + \frac{h}{2}k_i^1\right), & k_i^2 & \text{ is the slope at } x_i + \frac{h}{2} \text{ (interval middle)} \\ & \text{using } k_i^1 \text{ as slope,} \\ k_i^3 &= f\left(x_i + \frac{h}{2}, y_i + \frac{h}{2}k_i^2\right), & k_i^3 & \text{ is the slope at the interval middle} \\ & \text{using } k_i^2 \text{ as slope,} \\ k_i^4 &= f(x_i + h, y_i + hk_i^3), & k_i^4 & \text{ is the slope at } x_i + h \text{ (interval end)} \\ & \text{using } k_i^3 \text{ as slope.} \end{aligned}$$

The values in initial condition are respectively $x_0 = a$ and $y_0 = y(a)$. The linear approximation function of $y(x)$ on I is given by $\phi(x) = K_i x + y_i - K_i x_i$ for all $x \in [x_i, x_{i+1}]$ and $\phi(x_0) = y_0$. In the paper, when we will mention Runge–Kutta’s method, we will refer to the fourth order Runge–Kutta’s method.

To find parameters of the cognitive model from measures $M_{a,b,i} = \int_a^b y(t)dt$ on $[a, b]$, we propose the following optimization model based on Runge–Kutta’s numerical method:

Objective function:	$Min \left(\alpha \sum_{i=1}^m e_i^2 + f_{dm}(p) \right)$ where m is the number of measures,
Constraints:	$\begin{aligned} h_i &= (x_{i+1} - x_i) \text{ for all } i \in \llbracket 0, m - 1 \rrbracket, \\ y_{i+1} &= y_i + h_i K_i \text{ for all } i \in \llbracket 0, m - 1 \rrbracket, \\ K_i &= \frac{k_i^1 + 2k_i^2 + 2k_i^3 + k_i^4}{6} \text{ for all } i \in \llbracket 0, m - 1 \rrbracket, \\ k_i^1 &= f(x_i, y_i, p) \text{ for all } i \in \llbracket 0, m - 1 \rrbracket, \\ k_i^2 &= f\left(x_i + \frac{h_i}{2}, y_i + \frac{h_i}{2}k_i^1, p\right) \text{ for all } i \in \llbracket 0, m - 1 \rrbracket, \\ k_i^3 &= f\left(x_i + \frac{h_i}{2}, y_i + \frac{h_i}{2}k_i^2, p\right) \text{ for all } i \in \llbracket 0, m - 1 \rrbracket, \\ k_i^4 &= f\left(x_i + h_i, y_i + h_i k_i^3, p\right) \text{ for all } i \in \llbracket 0, m - 1 \rrbracket, \\ S_{i+1} &= \frac{h_i(y_i + y_{i+1})}{2} \text{ for all } i \in \llbracket 0, m - 1 \rrbracket, \\ M_{a,b,i} &= \sum_{j=ord(a)}^{ord(b)} S_j + e_i \text{ for all } i \in \llbracket 1, m \rrbracket, \end{aligned}$
Data:	$\begin{aligned} M_{a,b,i} & \text{ is the } i \text{th measure on } [a, b], \\ x_i & \text{ sorted abscissa of considered points,} \\ h_i & \text{ the step,} \\ \alpha & \text{ errors weight,} \\ ord(u) & \text{ returns the position of } u \text{ in } x, \end{aligned}$

Decision Variables:	<p>f differential equation $\frac{dy}{dx} = f(x, y, p)$ of the model,</p> <p>p parameters in differential equation,</p> <p>K_i, k_i^1, k_i^2, k_i^3 and k_i^4 are Runge–Kutta’s slopes,</p> <p>y_i points determined by the Runge–Kutta’s linear approximation,</p> <p>S_i trapezoid area with height $x_{i+1} - x_i$,</p> <p>f_{dm} objective function related to differential equation,</p> <p>e_i error of the ith measure.</p>
----------------------------	---

In this new optimization model, only the numerical method has been changed. As Runge–Kutta’s and Euler’s methods provide a linear approximation, the optimization model is identical to the Euler based optimization model presented previously, except that Euler’s slopes are replaced by Runge–Kutta’s slopes.

4.3 Optimization Model for Parameters Calculation of Cognitive Model

To determine parameters of the cognitive model, the Runge–Kutta based generic optimization model is applied. We used the same compromise between precision and solving time by choosing as Runge–Kutta’s points the start and the end of measure intervals. Moreover, the interval measure extremities are determined in the way that the number of ideas for one participant is equal to 1 (that is $\int_a^b o_i(t)dt = 1$).

The optimization model can be described as following:

<p>Objective function:</p> <p>(1) $Min \left(\frac{8}{15} \sum_{k=1}^n \sum_{i=1}^m e_{i,k}^2 + f_{dm}(a_k, b_k, c_k, d_k, f_k, m_k) \right)$</p> <p>where m is the number of measures,</p> <p>(2) $f_{dm}(a_k, b_k, c_k, d_k, f_k, m_k) = \frac{1}{15} \sum_{k=1}^n (a_k - 0.0235)^2$</p> <p>$+ \frac{1}{15} \sum_{k=1}^n (b_k - 0.035)^2 + \frac{1}{15} \sum_{k=1}^n (c_k - 0.0235)^2$</p> <p>$+ \frac{1}{15} \sum_{k=1}^n (d_k - 0.0235)^2 + \frac{1}{15} \sum_{k=1}^n (f_k - 0.035)^2$</p> <p>$+ \frac{1}{15} \sum_{k=1}^n (m_k - 0.2)^2$ with n the group size and $k \in \llbracket 1, n \rrbracket$,</p> <p>Constraints: for all $i \in \llbracket 0, m - 1 \rrbracket$, $k \in \llbracket 1, n \rrbracket$ and $p \in \llbracket 1, 4 \rrbracket$:</p> <p>(3) $h_i = t_{i+1} - t_i$,</p> <p>(4) $u_{i,k,1} = g_{i,k}$,</p> <p>(5) $u_{i,k,2} = \max \left(0, g_{i,k} + \frac{h_{i+1}}{2} f_{i,k,1}^g \right)$,</p> <p>(6) $u_{i,k,3} = \max \left(0, g_{i,k} + \frac{h_{i+1}}{2} f_{i,k,2}^g \right)$,</p> <p>(7) $u_{i,k,4} = \max \left(0, g_{i,k} + h_{i+1} f_{i,k,3}^g \right)$,</p> <p>(8) $v_{i,k,1} = s_{i,k}$,</p> <p>(9) $v_{i,k,2} = \max \left(0, s_{i,k} + \frac{h_{i+1}}{2} f_{i,k,1}^s \right)$,</p> <p>(10) $v_{i,k,3} = \max \left(0, s_{i,k} + \frac{h_{i+1}}{2} f_{i,k,2}^s \right)$,</p> <p>(11) $v_{i,k,4} = \max \left(0, s_{i,k} + h_{i+1} f_{i,k,3}^s \right)$,</p> <p>(12) $w_{i,k,1} = o_{i,k}$,</p>

\end{aligned}$$

Data:
 $M_{a,b,i,k}$ is the i th measure of the participant k on $[a, b]$,
 t_i boundary measures in chronological order,
 h_i measures duration,
 $ord(x)$ returns the position of x in t ,

Decision Variables:
 $a_k, b_k, c_k, d_k, f_k, r_k$ and m_k are model's parameters of participant k ,
 $u_{i,k,p}, v_{i,k,p}$ and $w_{i,k,p}$ are points for Runge–Kutta calculation,
 $K g_{i,k}, K s_{i,k}$ and $K o_{i,k}$ are Runge–Kutta's slopes for generation, memory and output processes,
 $g_{i,k}, s_{i,k}$ and $o_{i,k}$ the i th are ideas rate of participant k for generation, memory and output processes,
 $f_{i,k,p}^g, f_{i,k,p}^s$ and $f_{i,k,p}^o$ are differential equations of the model,
 $f_{dm}(a_k, b_k, m_k)$ is the dynamic model part of objective function,
 $S_{i,k}$ is the i th trapezoid surface for participant k ,
 $e_{i,k}$ is the error of the i th measure for participant k .

As for the non-cognitive problem, objective function minimizes errors (1) and the distance to reference values (2). The reference values used are those that have been established by Coskun and Yilmaz (2009). In this objective function, the minimization of errors (coefficient of $\frac{8}{15}$) is preferred to the minimization of distances between factors and their reference values (coefficient of $\frac{1}{15}$). In our notation, g, s and o mean that the designated variables refer to the generation, memorization and output processes. The constraints between (4) and (24) describe the application of the Runge–Kutta method for these processes. The variables $f_{i,k,1}^g$ (or $f_{i,k,1}^s, f_{i,k,1}^o$) correspond to k^1 Runge–Kutta's slopes, $f_{i,k,3}^g$ (or $f_{i,k,2}^s, f_{i,k,2}^o$) to k^2 , $f_{i,k,3}^g$ (or $f_{i,k,3}^s, f_{i,k,3}^o$) to k^3 and

Fig. 6 Cognitive model with initial and found by optimization parameters. **a** Generation process. **b** Memorization process. **c** Output process

$f_{i,k,4}^g$ or s or o to k^4 . For the generation process, the variables $u_{i,k,1}$ represent the variables $g_{i,k}$, $u_{i,k,2}$ the variables $g_{i,k} + \frac{h_{i+1}}{2} f_{i,k,1}^g$, $u_{i,k,3}$ the variables $g_{i,k} + \frac{h_{i+1}}{2} f_{i,k,2}^g$ and $u_{i,k,3}$ the variables $g_{i,k} + h_{i+1} f_{i,k,3}^g$. In that way, $f_{i,k,1}^g$ represent $f(g_{i,k})$, $f_{i,k,2}^g$ represent $f(g_{i,k} + \frac{h_{i+1}}{2} k^1)$, and so on. Let us note that $u_{i,k,p}$ are positive or null (max function). The variables $Kg_{i,k}$ are the final slopes of Runge–Kutta’s method. The same formalization is used for other processes, and the rest of constraints are identical to the non-cognitive problem.

We applied the optimization model described above on measures extracted from the model of the Fig. 4. The parameters obtained by the optimizer are : $\hat{p}_1 = (2.778, 0, 0, 0, 0.108, 0, 0.037, 0.772, 0.021, 0.227)$ and $\hat{p}_2 = (2.280, 0, 0, 0, 0.078, 0, 0.011, 0.766, 0.047, 0.176)$. In the Fig. 6, initial and computed by optimization solution functions are respectively plotted in full lines and in dotted lines⁶. As we can see in Fig. 6, in the output process, the approximation provided is quite good. In many cases, many solutions functions exist for the same output solution functions; which ex-

⁶ The initial model uses p_1 and p_2 parameters and the computed by optimization model \hat{p}_1 and \hat{p}_2 . In both models, solution functions are calculated by fourth order Runge–Kutta’s method with a step of $1E-3$

plains why in the example of the Fig. 6, the generation and the memorization solution functions are quite different to the initial ones.

4.4 Feasibility Tests

The proposed feasibility tests follow the same procedure than those of the non-cognitive model. Parameters are drawn at random and some measures are extracted. From these measures, the Runge–Kutta based optimization model is applied, providing new parameters and an error is calculated. Measures are extracted on four intervals ([0,5], [0,10], [0,15] and [0,20]), and errors are determined on these four intervals allowing us to test predictions. For each size, the procedure is repeated five times.

An extract of our tests results are presented in the Table 2. These tests have been performed by GAMS/CONOPT3 non-linear optimizer⁷. In our use context, the solving process must not take too much time, we thus choose to limit the optimization time to 1.30 min (set in configuration options of CONOPT3). As previously, the total solving time integrates the GAMS's compilation time and the CONOPT3's optimization time.

Let us note that for groups of 8 and 9 members, the solving time exceeds the limit of 1.30 minutes: this is due to the GAMS compilation time. In addition, for these groups, the optimizer did not complete its optimization process, and therefore did not provide the locally optimal solution but only a feasible solution. This explains why the solving time is approximately constant (about 1.35 min).

The errors are not too different between measure intervals and extrapolated intervals, which seems to confirm the adequacy of the Runge–Kutta based optimization model to our prediction context. Moreover, this optimization model can be directly applied to groups of small size (from 2 to 6). However, it requires further developments to reduce the solving time for groups larger than 6. In our tests, the solving time exceeds the limit of 1.30 min for groups of 10 participants.

4.5 Discussion

The presented fourth order Runge–Kutta based optimization model can be used when Euler's method is not enough precise and could result to an infeasible optimization problem. This method generally increases the precision but also the solving time. It shares many advantages and disadvantages with Euler's based problem, which are:

- Advantages:
 - Model parameters can be calculated only from measures,
 - The solving can be even fast (as for small groups in our tests),
 - It can be used when solution functions of differential equations are unknown, or when their integrals are also not known,
 - It processes cases where measures overlap,
 - It is more precise than Euler's based optimization model.

⁷ On a PC computer (Pentium Dual-Core E5200 2.5GHZ and 4 GO RAM) with Windows XP operating system.

– Disadvantages:

- Even if the model is more precise, Runge–Kutta’s method provides an approximation of solution functions,
- The optimization model requires an manual configuration
- As Euler’s method, Runge–kutta’s method is also sensitive of function variations inside steps ($x_{i+1} - x_i$).

In our application context, we intend to determine parameters of dynamic models during the brainstorming session with the presented optimization models. Thanks to these calculated parameters, we will be able to predict the number of ideas in the session future. Therefore, it does not necessarily need to compute new parameters after each measure (idea). Indeed, if current measures well fit to the solutions functions determined before with previous ideas, it is not required to reapply the proposed optimization models.

In their experimentations, Coskun and Yilmaz (2009) noted that in the first half of the brainstorming session, the non-cognitive model fit better to the number of ideas

recorded than the cognitive model, and conversely, the cognitive model was better in the second half of the session. Therefore, the use of the both models (non-cognitive and cognitive) and our both optimization models (Euler based and Runge–Kutta based) could be interesting for the prediction of ideas number.

5 Conclusion

In this paper, we presented an approach allowing the prediction of ideas number during a brainstorming session. This prediction is based on two dynamic models of brainstorming, the non-cognitive and the cognitive models proposed by Brown and Paulus (1996), and extended by Coskun and Yilmaz (2009). These models describes for each participant, the evolution of ideas number over time according to three social factors (decay, blocking and matching), and are formalized by differential equations. The solution functions of these models offer a precise description of ideas number over time. Through them, it is then possible to calculate the number of ideas of each participant on any time intervals and thus in the future⁸. However, to be able to compute solution functions, it is necessary to determine the parameters of these models.

In many dynamic models, analytical solution functions or their integrals are unknown. In our approach, we propose to use optimization model for model parameters calculation in which solution functions are approximated by numerical methods. In our context of prediction, we want to determine models' parameters in real-time (that is during the brainstorming session), therefore the time of parameters calculation is very important and must be reasonable.

We developed a generic optimization model based on Euler's numerical method and we applied it to the non-cognitive model. Through artificial tests, this optimization model appears appropriate to the parameters calculation of the non-cognitive, and satisfies our time constraint. Moreover, these tests confirm the adequacy of the proposed approach to predict the ideas number in the future. However, the Euler based generic optimization model can not be applied to the cognitive model on measure intervals. We then proposed the use of a more precise numerical method, the fourth order Runge–Kutta's method. A new generic optimization model based on it for parameters calculation was presented, and we applied it to the cognitive model. Our tests showed the adequacy of this new optimization model to our prediction context. This optimization model can be directly applied to groups of small size (from 2 to 6), however requires further developments to reduce parameters calculation time for groups larger than 6.

We believe that our approach for determining parameters of dynamic models from measurements can be useful in many other situations, either by adapting the generic optimization models proposed or by changing the numerical method. Some advantages of this approach are: models parameters can be calculating only from measures, the parameters calculation time may be short, it can be used when solution functions or their integral functions are not known, the measures can overlap, and the change of numerical method is relatively easy. Some disadvantages are: numerical methods

⁸ Which we call prediction.

provide an approximation of solution functions, the optimization model requires hand configuration and the proposed numerical methods are sensitive to the function variations inside steps.

This approach will be tested on face to face real brainstorming sessions by using microphones to measure the duration of ideas production, and in electronic brainstorming sessions by using a timer. Through these experimentations, it might be possible to study in more details the eventual dynamic of the social factors (parameterization of the dynamic models). We also plan to extend this work to ideas quality by adapting it to the Bounded Ideation Theory proposed by Briggs and Reinig (2010). Finally, the proposed predictions will be integrated to our efficiency measure of decision making meetings (see Camilleri and Zarat 2009) and will contribute to our GDSS facilitation tool.
