Cybersecurity threats and vulnerabilities are causing substantial financial losses for governments and organizations all over the world. Cybersecurity criminals are stealing more than one billion dollars from banks every year by exploiting vulnerabilities caused by bank users' computer misuse. Cybersecurity breaches are threatening the common welfare of citizens since more and more terrorists are using cyberterrorism to target critical infrastructures (e.g., transportation, telecommunications, power, nuclear plants, water supply, banking) to coerce the targeted government and its people to accomplish their political objectives. Cyberwar is another major concern that nations around the world are struggling to get ready to fight. It has been found that intentional and unintentional users' misuse of information systems (IS) resources represents about 50% to 75% of cybersecurity threats and vulnerabilities to organizations. Computer Crime and Security Survey revealed that nearly 60% of security breaches occurred from inside the organization by users.

Computer users are one of the weakest links in the information systems security chain, because users seem to have very limited or no knowledge of user computer self-efficacy (CSE), cybersecurity countermeasures awareness (CCA), and cybersecurity skills (CS). Users' CSE, CCA, and CS play an important role in users' computer misuse intention (CMI). CMI can be categorized as unauthorized access, use, disruption, modification, disclosure, inspection, recording, or destruction of information system data. This dissertation used a survey to empirically assess users' CSE, CCA, CS, and computer misuse intention (CMI) at government agencies. This study used Partial Least Square (PLS) technique to measure the fit of a theoretical model that includes seven independent latent variables (CSE, UAS-P, UAS-T, UAC-M, CCS, CIS, & CAS) and their influences on the dependent variable CMI. Also, PLS was used to examine if the six control variables (age, gender, job function, education level, length of working in the organization, & military status such as veteran) had any significant impact on CMI.

119
120

This study included data collected from 185 employees of a local and state transportation agency from a large metropolitan in the northeastern United States. Participants received

121 an email invitation to take the Web-based survey. PLS was used to test the four research
122 hypotheses. The results of the PLS model showed that UAC-M and CIS were significant
123 contributors ($p < .05$) to CMI. UAC-M was a significant contributor ($p < .05$) to CCS.
124 UAS-P was a significant contributor ($p < .05$) to CAS. CSE was the most significant
125 contributor ($p < .001$) to CCS, while it did not show a significance contribution towards
126 CMI. It can be concluded that UAC-M and CIS play a significant role on CMI. This
127 investigation contributes to the IS and cybersecurity practice by providing valuable
128 information that can be used by government agencies in an effort to significantly reduce
129 computer users' abuse, while increasing productivity and effectiveness.

ACKNOWLEDGEMENTS

I would like to dedicate this to God for his unconditional love and guidance. To my mother who introduced me to God and showed me that everything is possible with faith and hard work. My two sisters and brother for their prayers, love, and support. To my wife Soojin, kids Dahae, Joohee, Isaac, and Joseph for all the love and joy in my life.

Special thanks to my advisor, Dr. Yair Levy, for his leadership, guidance, and support throughout this rigorous dissertation process. I have learned so much from Dr. Levy. I also want to thank my committee members, Dr. Anat Zeelim-Hovav and Dr. William L. Hafner for all their helpful comments and support throughout this process. I like to thank Dr. Ling Wang for helping me with IRB.

Finally, I would like to express my appreciation to Tariq, Steven, Deborah, Jerome, Anthony, Chuck, and others for helping me with the survey.

Chapter 1 Introduction

249

250 **Background**

251 The fast growing cybersecurity threats and vulnerabilities are causing substantial
252 financial losses for governments and organizations all over the world (The White House,
253 2009). Cyber-attacks, hacking, and computer misuse by employees are costing millions
254 of dollars to organizations around the world every day (Gal-Or & Ghose, 2005).

255 Cybersecurity breaches have increased rapidly over the years, and they continue growing
256 at an alarming rate (Veiga & Eloff, 2007). One of the biggest challenges nowadays in
257 cybersecurity is the behavior of users due to their limited cybersecurity skills (Thomson
258 & Solms, 2005). Thus, this study focused on assessing the role of user computer self-
259 efficacy (CSE), cybersecurity countermeasures awareness (CCA), and cybersecurity
260 skills (CS) toward computer misuse intention (CMI) at government agencies.

261 CSE, CCA, and CS were found to play an important role in reducing CMI, human
262 error in data processing, information theft, digital fraud, and misuse of computer assets in
263 organizations (D'Arcy, Hovav, & Galletta, 2009; Drevin, Kruger, & Steyn, 2007). It
264 appears that users are one of the weakest links in the information systems (IS) security
265 chain, because users seem to have very limited or no knowledge of CSE, CCA, and CS
266 (Albrechtsen, 2007; Clifford, 2008). CSE, CCA, and CS are essential in educating and
267 developing users' awareness and skills to help reduce cybersecurity vulnerabilities such
268 as CMI (Clifford, 2008; D'Arcy et al., 2009).

269 The structure of this document is in the following order. Problem statement,
270 dissertation/research goal, research questions, relevance and significance of the study,
271 brief review of the literature, barriers and issues, approach, results, conclusions,
272 implications, recommendations, summary, resources, and references.

273

274 **Problem Statement**

275 The research problem that this study addressed was the fast growing cybersecurity
276 threats and vulnerabilities from users' computer misuse that are causing substantial
277 financial losses for governments and organizations all over the world (Blanke, 2008;
278 D'Arcy et al., 2009; Gal-Or & Ghose, 2005). Axelrod (2006) defined cybersecurity as
279 “the prevention of damage to, unauthorized use of, exploitation of, and, if needed, the
280 restoration of electronic information and communications systems to ensure
281 confidentiality, integrity and availability” (p. 1). Cyber-attacks, hacking, and computer
282 misuse by users (e.g., employees, consultants, contractors, & business partners) are
283 costing millions of dollars to organizations around the world every day (Gal-Or & Ghose,
284 2005). Torkzadeh and Lee (2003) defined users as “individuals who may use codes
285 written by others” (p. 608). Computer users are individuals that interact or use computer
286 software applications in order to perform their work or achieve their intended actions,
287 while do not write computer code on their own (Torkzadeh & Lee, 2003). Straub (1990)
288 defined computer misuse as “unauthorized deliberate and internally recognizable misuse
289 of assets of the local organizational information system by individuals” (p. 527). D'Arcy
290 et al. (2009) defined computer misuse intention as an “individual's intention to perform a
291 behavior that is defined by the organization as a misuse of IS resources” (p. 81).

292 Cybersecurity criminals are stealing more than one billion dollars from banks every year
293 by exploiting vulnerabilities caused by bank users' computer misuse (Farrell & Riley,
294 2011). It has been found that intentional and unintentional users' misuse of information
295 systems resources represents about 50% to 75% of cybersecurity threats and
296 vulnerabilities to organizations (D'Arcy et al., 2009). D'Arcy and Hovav (2007) claimed
297 that users' computer misuse is a very serious problem for organizations. Users' computer
298 misuse includes sending inappropriate emails using their organization's email,
299 installation of unlicensed and unauthorized computer software, unauthorized
300 modification of computerized data, access to unauthorized computers, password sharing,
301 and password stealing. Blanke (2008) found that users' computer misuse is one of the
302 biggest cybersecurity issues in organizations all over the world. According to a survey by
303 Ernst and Young, security incidents can cost companies between \$17 and \$28 million for
304 each occurrence (Veiga & Eloff, 2007). The 2010/2011 Computer Crime and Security
305 Survey (2011) revealed that approximately 59.1% of security breaches occurred from
306 inside the organization by users. A White House report (2009) that addressed the
307 systemic loss of United States (U.S.) economic value estimated that in 2008 alone the
308 loss from intellectual property to data theft was up to one trillion dollars. Cybersecurity
309 breaches have increased rapidly over the years and they continue growing at an alarming
310 rate (Veiga & Eloff, 2007). One of the biggest challenges nowadays in cybersecurity is
311 the behavior of users due to the user's limited cybersecurity skills (Thomson & Solms,
312 2005). Yet, limited work has been done to study cybersecurity skills, let alone to develop
313 viable instruments to measure such skills.

314 Government agencies are not exempt from cybersecurity attacks and
315 vulnerabilities caused by users' computer misuse. According to Clarke and Knake
316 (2010), several government agencies have been hit by cybersecurity attacks. Many U.S.
317 government agencies such as the Central Intelligence Agency (CIA), Department of
318 Defense (DoD), Department of Homeland Security (DHS), Federal Bureau of
319 Investigation (FBI), and Federal Aviation Administration (FAA) are few examples of
320 agencies that have been attacked by cybercriminals recently (Clarke & Knake, 2010;
321 Rosenzweig, 2012). In addition, cybersecurity breaches are threatening the common
322 welfare of citizens since more and more terrorists are using cyberterrorism to target
323 critical infrastructures (e.g., transportation, telecommunications, power, nuclear plants,
324 water supply, banking) to terrorize and coerce the targeted government and its people to
325 accomplish their political objectives (Foltz, 2004). Terrorist organizations can easily hire
326 outside hackers and users from the targeted organization to work for them (Foltz, 2004).
327 Foltz (2004) defined cyberterrorism as "concerted, sophisticated attacks on networks" (p.
328 154). Cyberwar is another major concern that nations around the world are struggling to
329 get ready to fight (Clarke & Knake, 2010). Clarke and Knake (2010) defined cyberwar as
330 "actions by a nation-state to penetrate another nation's computers or networks for the
331 purposes of causing damage or disruption" (p. 6). Cybersecurity has become one of the
332 top priorities of the U.S. government (The White House, 2009). President Obama
333 mandated a comprehensive review to assess the national cybersecurity policies and
334 structures in order to evaluate the ever increasing cybersecurity attacks, system
335 vulnerabilities, and information system misuse (The White House, 2009). It is important
336 to understand that cybersecurity criminals, cyber-terrorists, and cyber-warriors are

337 exploiting and hacking into IS vulnerabilities that are often caused by users' intentional
338 and unintentional computer misuse (Blanke 2008; Clarke & Knake, 2010).

339 Users' computer self-efficacy (CSE), cybersecurity countermeasures awareness
340 (CCA), and cybersecurity skills (CS) play an important role in users' computer misuse
341 intention (CMI) (Blanke, 2008; D'Arcy et al., 2009; Ruighaver, Maynard, & Chang,
342 2007). Compeau and Higgins (1995) defined self-efficacy "as beliefs about one's ability
343 to perform a specific behavior" (p. 146). Computer self-efficacy pertains to individuals'
344 judgment of their capabilities to use computers in various situations to perform a task
345 successfully (Compeau & Higgins, 1995; Chau, 2001; Marakas, Yi, & Johnson, 1998).
346 Compeau and Higgins (1995) claimed that studies have uncovered a close relationship
347 between self-efficacy, skill, and individual behaviors regarding technology usage and
348 adoption. Skill is the combined knowledge, ability, and experience that allow an
349 individual to successfully perform an action, while computer self-efficacy (CSE) is the
350 perception of the ability to successfully perform an action using a computer (Compeau &
351 Higgins, 1995; McCoy, 2010). Chan, Woon, and Kankanhalli (2005) conducted a study
352 based on Compeau and Higgins' (1995) CSE focusing on breaches in information
353 security. Chan et al. (2005) found that users' perception of CSE and the organization's
354 cybersecurity view positively impact their compliant behavior. Their study concluded
355 that compliant behavior can be promoted by increasing users' CSE and enhancing
356 awareness of the importance of cybersecurity to them and their organization (Chan et al.,
357 2005). D'Arcy and Hovav (2009) stated that "research that has examined risky decision
358 making among various groups suggests that there is a significant relationship between
359 perceptions of self-efficacy and risk-taking behavior" (p. 61). Wyatt (1990) found several

360 risky behaviors (e.g., computer misuse) among college students and stated that self-
361 efficacy was the principle variable influencing risk-taking behavior. D’Arcy and Hovav
362 (2009) found that self-efficacy influences risk-taking behavior through opportunity
363 recognition. They suggested that CSE appears to have different effects depending on the
364 computer misuse activity (i.e., ones that apply to computer savvy users & ones that apply
365 to computer non-savvy users). CCA comprises user awareness of security policy,
366 security-training programs, computer monitoring, and computer sanctions (Aakash, 2006;
367 D’Arcy et al., 2009). D’Arcy et al.’s (2009) study found that cybersecurity
368 countermeasures such as the four aforementioned dimensions of user security and
369 computer awareness are each effective in discouraging users’ CMI. Users’ computer
370 misuse is a serious and very costly threat to an organization’s financial stability (D’Arcy
371 & Hovav, 2007). Although, the aforementioned studies have focused on addressing CMI,
372 these studies have not investigated the role of skills, specifically cybersecurity skills, into
373 their model.

374 Users are one of the weakest links in the IS security chain because many users
375 appear to have limited or no cybersecurity skills (Albrechtsen, 2007; Clifford, 2008).
376 Most users do not understand the importance of protecting computer information
377 systems, and this lack of understanding is reflected in their negligence in cybersecurity
378 practices (Thomson & Solms, 2005). Users cannot be held responsible for cybersecurity
379 problems if they are not educated and trained to acquire the right skills to be able to
380 identify what such security problems are as well as what they should do to prevent them
381 (Solms & Solms, 2004). Boyatzis and Kolb (1991) defined skill as a “combination of
382 ability, knowledge and experience that enables a person to do something well” (p. 280).

383 Skill is the ability to understand and make use of different intellectual abilities (i.e.
384 knowledge), combined with the individual's prior experience to achieve the most
385 appropriate action for the best result. For example, the combined ability, knowledge, and
386 experience to install, configure, and/or maintain antivirus software to protect the
387 operating systems of a computer is a type of a computer skill (Levy, 2005; Torkzadeh &
388 Lee, 2003). For most users, a computer system is a tool to perform their job
389 responsibilities as efficiently as possible, while they view cybersecurity as a barrier rather
390 than a necessity due to their lack of cybersecurity skills (Tsohou, Karyda, Kokolakis, &
391 Kiountouzis, 2006).

392 CSE, CCA, and CS all play an important role in reducing CMI, human error in
393 data processing, information theft, digital fraud, and misuse of computer assets in
394 organizations (D'Arcy et al., 2009; Drevin et al., 2007). Although all of CCA's user
395 awareness of security policy (UAS-P), user awareness of security-training programs
396 (UAS-T), user awareness of computer monitoring (UAC-M), and user awareness of
397 computer sanctions (UAC-S) play a key role in reducing users' CMI in their
398 organizations (D'Arcy et al., 2009; Ruighaver et al., 2007), D'Arcy et al. (2009)
399 suggested that perceived severity of sanctions appear to have a significant direct effect on
400 users' CMI. Unfortunately, organizations are reluctant to invest in CCA programs due to
401 their lack of knowledge of the cybersecurity risks and cost associated with implementing
402 CCA programs (Ruighaver et al., 2007). Thomson and Solms (2005) claimed that
403 cybersecurity should become second nature behavior in users' daily activity in order to
404 help reduce their computer misuse. Increasing CCA appears to increase users'
405 perceptions of the negative impact that computer misuse could cause to their organization

406 (D'Arcy et al., 2009; Thomson & Solms, 2005). CCA is essential in educating and
407 developing users' cybersecurity skills to help reduce cybersecurity vulnerabilities
408 (Clifford, 2008; D'Arcy et al., 2009). While significant research has been done in the
409 cybersecurity domain, very little attention has been given to the study of user CMI
410 (D'Arcy et al., 2009; Torkzadeh & Lee, 2003). According to Ajzen (1989), behavioral
411 intention is the individual's intention to perform or not perform a specific behavior.
412 Based on Ajzen's definition and for the purpose of this study, CMI is defined as a user's
413 intention to perform computer misuse. A user's CMI is the indicator that the individual
414 may have the behavioral intention to use the computer to commit computer misuse in his
415 or her organization and negatively affect cybersecurity. Government agencies are under a
416 lot of pressure to improve cybersecurity (The White House, 2009). Thus, it appears that
417 additional empirical investigation on the role of computer self-efficacy (CSE),
418 cybersecurity countermeasures awareness (CCA), and cybersecurity skills (CS) towards
419 computer misuse intention (CMI) is necessary since cybersecurity plays a crucial part of
420 the world's economy, infrastructure, and military today (Clarke & Knake, 2010; D'Arcy
421 et al., 2009).

422

423 **Research Goals**

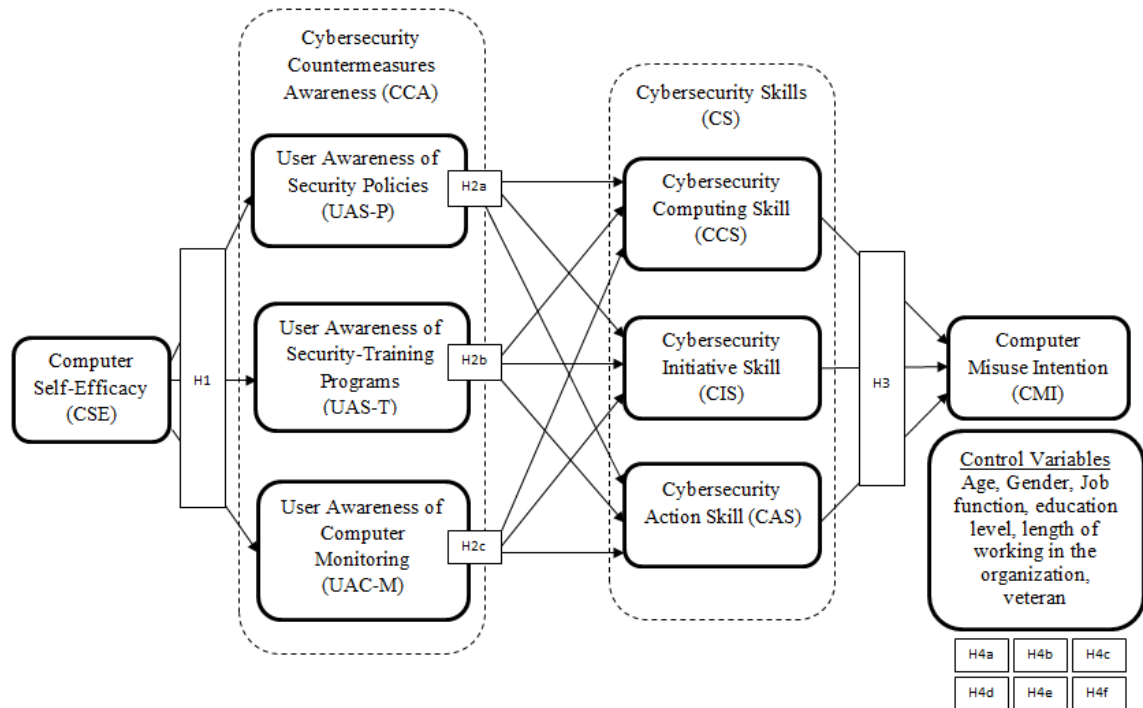

424 The main goal of this research study was to empirically test a predictive model on
425 the impact of computer self-efficacy (CSE), cybersecurity countermeasures awareness
426 (CCA), and cybersecurity skills (CS) on computer misuse intention (CMI) at government
427 agencies. The need for this study is demonstrated by D'Arcy et al.'s (2009) study on user
428 awareness of security countermeasures and its impact on information systems misuse;

429 Blanke's (2008) research on employee's intention to commit computer misuse in
430 business environments; Aakash's (2006) research on antecedents of information system
431 exploitation in organizations; as well as Torkzadeh and Lee's (2003) study on the
432 measures of user computing skills. D'Arcy et al. (2009) claimed that intentional and
433 unintentional insider misuse of information systems resources (i.e., computer misuse)
434 represents a significant threat to organizations. Blanke (2008) indicated that American
435 businesses alone will lose around \$63 billion each year due to employees' computer
436 misuse. Aakash (2006) pointed out that organizations should invest in cybersecurity
437 awareness programs, education, training, and sanctions to increase employees'
438 cybersecurity compliance. Torkzadeh and Lee (2003) reported on the need to develop a
439 measuring instrument to properly assess user computing skills. Unfortunately, limited
440 numbers of research studies have been done on CSE, CCA, and CS toward CMI (Blanke,
441 2008; Clarke & Knake, 2010; D'Arcy et al., 2009). D'Arcy et al. (2009) stated that users'
442 computer misuse is the source of 50% to 75% of security incidents. Therefore, an
443 investigation on user's CMI appears to be warranted.

444 This study focused on three key independent variables (CSE, CCA, & CS
445 constructs) as potential predictors for CMI as described in Figure 1. The theoretical
446 foundation is based on general deterrence theory (GDT). GDT posits that individuals can
447 be dissuaded from committing antisocial acts through the use of countermeasures, which
448 include strong disincentives and sanctions relative to the act (Straub & Welke, 1998). For
449 example, due to the lack of cybersecurity skills training and sanctions, an organizational
450 user may fail to follow procedures, which leads to data loss, destruction, or a failure of
451 data integrity (Straub & Welke, 1998).

466

Cybersecurity computing skill (CCS), cybersecurity initiative skill (CIS), and cybersecurity action skill (CAS) are considered as the three major facets of users' cybersecurity skill (CS) (Aakash, 2006; Blanke, 2008; Levy, 2005; Torkzadeh & Lee, 2003). Levy (2005) defined computing skill as the “ability to use computers and computer networks to analyze data and organize information” (p. 6). He also defined initiative skill as the “ability to seek out and take advantage of opportunities” (p. 6). Levy (2005) defined action skill as the “ability to commit to objectives, to meet deadlines” (p. 6). Accordingly, the cybersecurity computing skill was defined in this research as the ability to use protective tools (e.g., encryption) to protect computers and computer networks to secure data and information systems. The cybersecurity initiative skill was defined as the ability to seek out and take advantage of security software (e.g., antivirus

467 program) and best practices. Lastly, the cybersecurity action skill was defined as the
468 ability to commit to objectives and to meet security compliance (e.g., laptop encryption).
469 The three facets (i.e., CCS, CIS, & CAS) of users' cybersecurity skill are important since
470 a user needs to have adequate levels of these three cybersecurity skills combined in order
471 to demonstrate appropriate overall cybersecurity skill (Aakash, 2006; Blanke, 2008;
472 Levy, 2005; Torkzadeh & Lee, 2003). Computer misuse can be described as
473 unauthorized, deliberate, and internally recognizable misuse of assets of the local
474 organizational IS by individuals, including violations against hardware, programs, data,
475 and computer service (Straub, 1986).

476 This research was built on previous studies conducted by D'Arcy et al. (2009),
477 Levy (2005), Blanke (2008), Torkzadeh and Lee (2003), as well as Aakash (2006), by
478 investigating the contributions of users' CSE, CCA, and CS toward CMI in an attempt to
479 validate a model to assess users' CMI in a government agency. The first specific goal of
480 this study was to empirically assess CSE and its contribution to CCA dimensions. The
481 second goal of this study was to empirically assess CCA dimensions and its contribution
482 to CS. The third goal of this study was to empirically assess CS and its contribution to
483 CMI. The fourth goal of this study was to empirically assess the contribution of the six
484 control variables: age, gender, job function (i.e., officer, security operator, managerial,
485 operations, technical, professional staff, and administrative staff), education level, length
486 of working in the organization, and military status (e.g., veteran) to CMI. The last goal
487 was to empirically assess the fit of the model by using CCA (i.e., UAS-P, UAS-T, &
488 UAC-M), CCA (i.e., UAS-P, UAS-T, & UAC-M), CS (i.e., CCS, CIS, & CAS), CMI,
489 and control variables.

490 The four hypotheses that this study addressed are:

491 H1: Computer self-efficacy (CSE) of users will show significant positive
492 influence on the cybersecurity countermeasures awareness dimensions (UAS-P,
493 UAS-T, & UAC-M).

494 H2a: User awareness of security policy (UAS-P) will show significant positive
495 influence on the three cybersecurity skills (CCS, CIS, & CAS).

496 H2b: User awareness of security-training programs (UAS-T) will show significant
497 positive influence on the three cybersecurity skills (CCS, CIS, & CAS).

498 H2c: User awareness of computer monitoring (UAC-M) will show significant
499 positive influence on the three cybersecurity skills (CCS, CIS, & CAS).

500 H3: The three cybersecurity skills (CCS, CIS, & CAS) of users will show
501 significant negative influence on Computer Misuse Intention (CMI).

502 H4a: Users' *age* will show no significant influence on Computer Misuse Intention
503 (CMI).

504 H4b: Users' *gender* will show no significant influence on Computer Misuse
505 Intention (CMI).

506 H4c: Users' *job function* will show no significant influence on Computer Misuse
507 Intention (CMI).

508 H4d: Users' *education level* will show no significant influence on Computer
509 Misuse Intention (CMI).

510 H4e: Users' *length of working in the organization* will show no significant
511 influence on Computer Misuse Intention (CMI).

512 H4f: Users' *military veteran status* (i.e. 'yes' or 'no') will show no significant
513 influence on Computer Misuse Intention (CMI).

514

515 **Relevance and Significance**

516 *Relevance of this Study*

517 There are many protective technologies, such as firewall, antivirus software, and
518 intrusion detection systems implemented in organizations to protect them from
519 computer misuse (Dinev, Goo, Hu, & Nam, 2008). These protective technologies, which
520 are designed to protect users from computer viruses, spyware, worms, and other malware
521 (e.g., hacking tools), suffer from many complexities and vulnerabilities such as lack of
522 proper software configuration and updates (Dinev et al., 2008). It appears that
523 information security practitioners and managers pay more attention to protective
524 technologies to mitigate security threats than to the security risks caused by users due to
525 the lack of cybersecurity training and/or skills (Rezgui & Marks, 2008). Rezgui and
526 Marks (2008) defined information security as "the concepts, techniques, technical
527 measures, and administrative measures used to protect information assets from deliberate
528 or inadvertent unauthorized acquisition, damage, disclosure, manipulation, modification,
529 loss, or use" (p. 243). They also defined risk as "the potential that a given threat will
530 exploit vulnerabilities of an asset or group of assets" (Rezgui & Marks, 2008, p. 243).

531 Users play a large role in information security (Veiga & Eloff, 2007). Many users
532 are complacent about potential computer security risks when protective technologies
533 (e.g., antivirus software) are not used or installed in their computer. They are willing to
534 accept the security risks rather than addressing them due to the nuisances caused by

535 security measures and cost (Dinev et al., 2008). It appears that fighting effectively against
536 information security risks caused by malicious and harmful applications (e.g., viruses,
537 worms, spyware, or malware) cannot be solely accomplished by using protective
538 information technologies (IT). Therefore, assessing the role of user CSE, CCA, and CS
539 toward CMI seems to be warranted (Blanke, 2008; D'Arcy et al., 2009; Dinev et al.,
540 2008; Torkzadeh & Lee, 2003). Dinev et al. (2008) claimed that a "computer user that is
541 aware of the security threats of spyware will be more motivated to use an anti-spyware"
542 (p. 8). The relevance of this study to the fast growing cybersecurity threats and
543 vulnerabilities is by assessing the role of user CSE, CCA, and CS toward CMI.
544 According to the White House (2009), cybersecurity awareness, education, and training
545 are important to develop users' cybersecurity skills in digital safety, ethics, and security
546 to protect them from ever increasing cybersecurity attacks. This study provides
547 measurable data to cybersecurity practitioners and IT managers. This study helps
548 cybersecurity practitioners and IT managers justify funding for cybersecurity programs
549 for end users' cybersecurity skill development. In addition, this study contributes to the
550 research community by providing its findings for further research; this study also expands
551 the body of knowledge (BoK) in the area of user CSE, CCA, and CS roles toward CMI
552 (Besnard & Arief, 2004; Blanke, 2008; D'Arcy et al., 2009; Dinev et al., 2008; Rezgui &
553 Marks, 2008; Torkzadeh & Lee, 2003; Veiga & Eloff, 2007; White House, 2009).

554 *Significance of this Study*

555 The 2010/2011 Computer Crime and Security Survey (2011) revealed that
556 approximately 59.1% of security breaches occurred from inside the organization by users.
557 More than 77% of computer attacks originate in the form of users' computer misuse as

558 they activate viruses and worms embedded in emails and pirated software (e.g., songs,
559 movies, games, or applications) they obtain (Chan et al., 2005). Constantly, users
560 computer misuse, international terrorists, hackers, and cyber-criminal groups are
561 targeting U.S. citizens, commerce, critical infrastructure, and government with the
562 intentions to compromise, steal, change, or completely destroy information (The White
563 House, 2009). Organizations are losing millions of dollars every day due to cybersecurity
564 breaches (The White House, 2009). Today, cybersecurity has a direct impact on and is a
565 threat to the nations' security; cyberwar is a reality not science fiction anymore (Clarke &
566 Knake, 2010).

567 It appears that intentional and unintentional user computer misuse is one of the
568 greatest cybersecurity threats and vulnerabilities to organizations (Blanke, 2008; D'Arcy
569 et al., 2009). Cybersecurity threats are on a steady rise, thus, the U.S. government is
570 constantly increasing the number of professionals to mitigate cybersecurity threats in
571 both public and private sectors (The White House, 2009). One of the U.S. government's
572 top priorities is to promote cybersecurity risk awareness for its citizens and build an
573 education system that will enhance understanding of cybersecurity (The White House,
574 2009). The significance of this study stem from the results of the assessment on the role
575 of users' CSE, CCA, and CS toward CMI at government agencies, as well as the
576 investigation of the impact of users' CSE, CCA, and CS on CMI. The results of this study
577 were expected to provide better understanding on cybersecurity gaps and threats in
578 government agencies (Aakash, 2006; Besnard & Arief, 2004; Blanke, 2008; D'Arcy et
579 al., 2009; Dinev et al., 2008; Rezgui & Marks, 2008; Torkzadeh & Lee, 2003; Veiga &
580 Eloff, 2007).

581

582 Barriers and Issues

583 The main barrier of this study was that cybersecurity studies are not widely
584 conducted in U.S. government agencies due to the government agencies' strict union
585 rules, organizational politics, as well as managerial support and funding. The first issue of
586 this study was that the participants were not willing to share information about their
587 knowledge of cybersecurity skills due to their concerns about their privacy (Straub, 1986;
588 Straub & Nance, 1990). In order to address the participants' concern, they were informed
589 that their participation was voluntary. They were told that their survey responses would
590 be anonymous to ensure confidentiality as well as privacy of each participant and that any
591 data collected would be used for this study only. The second issue was that the number of
592 participants was limited. The main reason for the limited sample size was because this
593 cybersecurity survey was voluntary. Therefore, an explanation of the importance of their
594 participation and the value of the results of the study to the organization were
595 communicated to participants and senior management prior to the survey. In addition, the
596 time collecting and analyzing the data was lengthy due to the need of a review of the
597 survey questions by an expert panel before collecting data. Lastly, another issue in
598 conducting this study was the need for institutional review board (IRB) approval. Given
599 that the study involved human subjects, the instruments and protocols used had to be
600 approved by the University's IRB prior to the study being conducted. IRB approval was
601 obtained to conduct this research study.

602

603 Definition of Terms

- 604 **Computer misuse intention (CMI)** – An individual’s intention to perform a behavior
605 that is defined by the organization as a misuse of IS resources (D’Arcy et al., 2009).
- 606 **Computer self-efficacy (CSE)** – A judgment of one’s capability to use a computer
607 (Compeau & Higgins, 1995).
- 608 **Cybersecurity** – Prevention of damage to, unauthorized use of, exploitation of, and, if
609 needed, the restoration of electronic information and communications systems to ensure
610 confidentiality, integrity, and availability (Axelrod, 2006).
- 611 **Cybersecurity action skill (CAS)** – The ability to commit to objectives, to meet security
612 compliance (Levy, 2005).
- 613 **Cybersecurity initiative skill (CIS)** – The ability to seek out and take advantages of
614 security software (e.g., antivirus program) and best practices (Levy, 2005).
- 615 **Cybersecurity computing skill (CCS)** – The ability to use protective tools (e.g.,
616 antivirus software) to protect computers and computer networks to secure data and
617 information system (Levy, 2005).
- 618 **Cyberspace** – Independent network of IT infrastructures that includes the Internet,
619 telecommunications networks, computer systems, and embedded processors and
620 controllers in critical industries (The White House, 2009).
- 621 **Cyberterrorism** – Concerted, sophisticated attacks on networks (Foltz, 2004).
- 622 **Cyberwar** – Actions by a nation-state to penetrate another nation’s computers or
623 networks for the purposes of causing damage or disruption (Clarke & Knake, 2010).
- 624 **Information Security** - The concepts, techniques, technical measures, and administrative
625 measures used to protect information assets from deliberate or inadvertent unauthorized

626 acquisition, damage, disclosure, manipulation, modification, loss, or use (Rezgui &
627 Marks, 2008).

628 **Information System (IS)** – The system that governs the information technology
629 development, use, application, and influence on a business or corporation (Alvarez,
630 2002).

631 **Information Technology (IT)** –The acquisition, processing, storage, and dissemination
632 of vocal, pictorial, textual, and numerical information by a microelectronics-based
633 combination of computing and telecommunications (Caputo, 2010).

634 **Negative Technologies** – Tools used for breaking into systems and databases, such as
635 computer viruses and spyware (Dinev & Hu, 2007).

636 **Protective Technologies** – Technologies that are designed to deter, neutralize, disable, or
637 eliminate the negative technologies or their effectiveness, such as anti-virus software,
638 anti-spyware, firewalls, and intrusion detection technologies (Dinev & Hu, 2007).

639 **Risk** – The potential that a given threat will exploit vulnerabilities of an asset or group of
640 assets (Rezgui & Marks, 2008).

641 **Risky End-User Computing Behavior** – End-users sharing passwords, downloading
642 unauthorized software, and opening emails from unknown sources (Aytes & Connolly,
643 2004).

644 **Skill** – A combination of ability, knowledge, and experience that enables a person to do
645 something well (Boyatzis & Kolb, 1991).

646 **Statistical Package for the Social Sciences® (SPSS)** – A software tool utilized to
647 perform data analysis.

648 **Theory of Reasoned Action (TRA)** – Theory that demonstrates the links between
649 attitudes, beliefs, norms, intentions, and behaviors of individuals (Fishbein & Ajzen,
650 1975).

651 **User** – end-users or computer users are individuals who may develop their own
652 applications or use codes written by others (Torkzadeh & Lee, 2003).

653 **User awareness of computer monitoring (UAC-M)** – The awareness by users of
654 computer monitoring, which is tracking employees' Internet use, recording network
655 activities, and performing security audits (D'Arcy et al., 2009).

656 **User awareness of computer sanctions (UAC-S)** – The punishment for breaking the
657 cybersecurity rules set by the organization (D'Arcy et al., 2009).

658 **User awareness of security policy (UAS-P)** – The security policies with detailed
659 guidelines for the proper and improper use of organizational IS resources (D'Arcy et al.,
660 2009).

661 **User awareness of security-training programs (UAS-T)** – The programs that focus on
662 providing users with knowledge of the information security policies and skills necessary
663 to perform any required cybersecurity engagements (D'Arcy et al., 2009).

664 **Web-based Survey** – An online survey that has incorporated the functionality of the
665 Internet (Thomas, 2003).

666

667 **Summary**

668 Chapter one provided an introduction to this study, identified the research
669 problem, identified barriers to conducting this study, and provided an overall theoretical
670 position. The research problem that this study addressed was the fast growing

671 cybersecurity threats and vulnerabilities that are causing substantial financial losses on
672 governments and organizations all over the world. The main focus was on the users'
673 computer misuse intention (CMI) at government agencies. Valid literature supporting the
674 research problem and the need for this study was presented.

675 This chapter also presented the main goal for this study, and specific goals. The
676 main goal of this research study was to empirically test a predictive model on the impact
677 of computer self-efficacy (CSE), cybersecurity countermeasures awareness (CCA), and
678 cybersecurity skills (CS) on computer misuse intention (CMI) at government agencies.
679 This research was built on previous studies conducted by D'Arcy et al. (2009), Levy
680 (2005), Blanke (2008), Torkzadeh and Lee (2003), as well as Aakash (2006), by
681 investigating the contributions of user's CSE, CCA, and CS toward CMI in an attempt to
682 validate a model to assess user's CMI in a government agency. The first specific goal of
683 this study was to empirically assess CSE and its contribution to CCA dimensions. The
684 second goal of this study was to empirically assess CCA dimensions and its contribution
685 to CS. The third goal of this study was to empirically assess CS and its contribution to
686 CMI. The fourth goal of this study was to empirically assess if there is a significant
687 difference on the measured constructs based on age, gender, job function (i.e., job title),
688 education level, length of working in the organization, and military status (e.g., veteran).
689 The last goal was to empirically assess the fit of the model by using CSE, CCA (i.e.,
690 UAS-P, UAS-T, & UAC-M), CS (i.e., CCS, CIS, & CAS), CMI, and control variables.

691 There were a total of four hypotheses. H1 tested the CSE influence on the CCA
692 dimensions (i.e., UAS-P, UAS-T, & UAC-M). H2 (i.e., H2a, H2b, & H2c) tested the
693 CCA influence on the CS dimensions (i.e., CCS, CIS, & CAS). H3 tested the CS

694 influence on CMI. H4 (i.e., H4a, H4b, H4c, H4d, H4e, H4f, & H4g) tested for differences
695 based on CSE, CCA, CS, and CMI demographics variables.

696 The relevance and significance of the study were also presented in this chapter.
697 According to the literature, researchers are in agreement that more focus needs to be
698 placed on the aspects of users' computer misuse intention (CMI), as this significantly
699 influences the realization of a stronger cybersecurity (Blanke, 2008; D'Arcy et al., 2009;
700 Dinev et al., 2008; Torkzadeh & Lee, 2003). The significance of this study was expected
701 to be in the results of the assessment on the role of user CSE, CCA, and CS toward CMI
702 at government agencies, as well as the investigation of the impact of user CSE, CCA, and
703 CS on CMI. The results of this study provided better understanding on cybersecurity gaps
704 and threats in government agencies (Aakash, 2006; Besnard & Arief, 2004; Blanke,
705 2008; D'Arcy et al., 2009; Dinev et al., 2008; Rezgui & Marks, 2008; Torkzadeh & Lee,
706 2003; Veiga & Eloff, 2007). The methods to address barriers and issues were discussed.
707 The chapter ended with a definition of terms used throughout this study and any related
708 acronyms.

712

Chapter 2

713

Review of the Literature

714

715 **Introduction**

716 The literature review was presented to provide the theoretical foundation for this
717 study. Relevant computer self-efficacy (CSE), cybersecurity countermeasures awareness
718 (CCA) (i.e., UAS-P, UAS-T, & UAC-M), and cybersecurity skills (CS) (i.e., CCS, CIS,
719 & CAS) literature were reviewed as they play an important role in the user CMI in
720 government agencies. As suggested by Hart (1998), the literature review will focus on
721 “appropriate breadth and depth, rigor and consistency, clarity and brevity, and effective
722 analysis and synthesis” (p. 1). Constructs are an important part of the literature review
723 (Hart, 1998). In the following section, the constructs of this study are reviewed to provide
724 an understanding of the constructs, identify prior research that is focused on these
725 constructs, and discuss what is known about the constructs.

726

727 **Computer Self-Efficacy**

728 The construct of CSE proposed by Compeau and Higgins (1995) was based from
729 the general concept of self-efficacy that was founded on social cognitive theory
730 (Bandura, 1977, 1984). Self-efficacy is defined as “people’s judgments of their
731 capabilities to organize and execute courses of action required to attain designated
732 performances” (Bandura, 1986, p. 391). CSE pertains to individuals’ judgment of their

733 capabilities to use computers in various situations (Marakas et al., 1998). Compeau and
734 Higgins (1995) defined self-efficacy “as beliefs about one’s ability to perform a specific
735 behavior” (p. 146). Compeau and Higgins (1995) specified that CSE is “an individual’s
736 perception of his or her ability to use a computer in the accomplishment of a job task” (p.
737 193). Compeau and Higgins (1995) stated that individuals who are more confident in
738 their computer skills are more likely to expect positive results in their computer use.
739 Individuals’ judgment of their ability to complete a task using computers influences their
740 decision on how they will use computers (Piccoli, Ahmad, & Ives, 2001). Research has
741 shown that CSE applies a significant influence on an individual’s decision to use
742 computers to achieve various tasks (Compeau & Higgins, 1995; Marakas et al., 1998).
743 Literature suggests that CSE has a very high reliability and strong validity across
744 different contexts (Levy & Green, 2009).

745 Compeau and Higgins’ (1995) study of 1,020 randomly selected management
746 individuals found that CSE exerted “a significant influence on individuals’ expectations
747 of the outcomes of using computers, their emotional reactions to computers (affect and
748 anxiety) as well as their actual computer use” (p. 189). Compeau and Higgins (1995)
749 concluded that computer users with higher CSE had higher usage of computers, enjoyed
750 using them more, and possessed less computer related anxiety. According to D’Arcy
751 (2006), in a study of 507 individuals that use computers at work, “those that feel more
752 comfortable using computers can better comprehend the messages conveyed in security
753 awareness programs and therefore become more convinced of the organization’s
754 seriousness toward IT security” (p. 158). D’Arcy indicated based on research findings
755 that “computer self-efficacy influenced the effectiveness of security countermeasures” (p.

756 175). Compeau, Higgins, and Huff (1999) claimed that studies have uncovered a close
757 relationship between self-efficacy, skill, as well as individual reactions to technology
758 usage and adoption. Levy and Green (2009) found that CSE had a positive influence on
759 users' perceptions on ease of use and system usefulness. According to Levy and Green
760 (2009), "sailors who are comfortable working with IS and learning to use them on their
761 own, are more likely intended to use such systems" (p. 30).

762 Computer skill pertains to an individual's ability to utilize computer hardware and
763 software to design, develop, modify, and maintain specific applications for task-related
764 activities (Torkzadeh & Lee, 2003). Computer skills and computer self-efficacy are
765 interrelated due to the nature that both are outcomes of development and transformation
766 of the users' skill levels (Fischera, 1980; McCoy, 2010). For example, CSE is one's
767 perceptions about his/her ability to detect and remove hidden-malware in his computer
768 and skill is one's professed ability to detect and remove the hidden-malware in his/her
769 computer. Torkzadeh, Chang, and Demirhan (2006) suggested that CCA "significantly
770 improved computer and Internet self-efficacy" (p. 541). It appears that CSE plays an
771 important role in influencing users' perception on CCA (Piccoli et al., 2001).

772

773 **User Awareness of Security Policy**

774 UAS-P pertains to security policies. D'Arcy et al. (2009) stated that "security
775 policies contain detailed guidelines for the proper and improper use of organizational IS
776 resources" (p. 80). Security policies are similar to societal laws because they provide
777 information of what constitutes unacceptable conduct, which increases the user's
778 perceived threat of punishment for illegal behavior (J. Lee & Lee, 2002). Straub's (1990)

779 survey of 1,211 organizations found that users' awareness of security policies were
780 associated with a lower level of users' computer abuse. When users are not motivated to
781 follow or not aware of security policies designed to protect both users and organizations,
782 security fails (Boss, Kirsch, Angermeier, Shingler, & Boss, 2009).

783 D'Arcy et al. (2009) found that computer policy statements "prohibiting software
784 piracy and warning of its legal consequences resulted in lower piracy intentions" (p. 81).
785 The absence of security policies can lead to a misinterpretation of acceptable computer
786 use by users (Straub, 1990). This can lead users to assume that computer misuse is not
787 subject to enforcement and has little to no consequence (Straub, 1990). The effects of
788 computer security policies on users' computer misuse intention suggest that users'
789 awareness of the existence of security policies decreases the probability of engaging in
790 computer misuse (Blanke, 2008; D'Arcy et al., 2009). But more research is needed to
791 better assess the impacts of UAS-P on CMI.

792

793 **User Awareness of Security-Training Programs**

794 UAS-T pertains to security training programs. Security training programs focus
795 on providing users with knowledge of the information security policies needed to perform
796 any required cybersecurity activities (D'Arcy et al., 2009). D'Arcy et al. (2009) found
797 that information security training programs could help reduce users' CMI. Information
798 security training programs reinforce acceptable computer usage guidelines and emphasize
799 the potential consequences for computer misuse (D'Arcy et al., 2009). One of the biggest
800 causes of computer security failures is the lack of computer security training programs to
801 develop users' cybersecurity awareness (Boss et al., 2009). Information security

802 researchers have argued that information security training programs are essential in
803 helping users understand the impact of computer misuse (Blanke, 2008; D’Arcy et al.,
804 2009). It is important to evaluate the learners' tendency to actually apply what they have
805 learned and the confidence they have developed in their ability (Piccoli et al., 2001).

806 An UAS-T program includes ongoing efforts to convey awareness to users about
807 cybersecurity risks in the organizational environment, emphasizing recent actions against
808 users that committed computer misuse and increasing users’ awareness of their
809 responsibilities regarding organizational information resources (D’Arcy et al., 2009;
810 Straub & Welke, 1998). Straub and Welke (1998) stated that the primary reason for
811 initiating UAS-T programs is to “convince potential abusers that the company is serious
812 about security and will not take intentional breaches of this security lightly” (p. 445).
813 UAS-T has a positive influence on user CS by providing information about acceptable
814 and unacceptable usage of information systems, punishment associated with computer
815 abuse, and awareness of organizational enforcement activities (Wybo & Straub, 1989).
816 Wybo and Straub (1989) found that UAS-T has a positive effect on three cybersecurity
817 skills (CCS, CIS, & CAS). However, additional research is required to better assess the
818 contribution of UAS-T on CS.

819

820 **User Awareness of Computer Monitoring**

821 UAC-M is often used by organizations to gain compliance with rules and
822 regulations (D’Arcy et al., 2009). D’Arcy et al. (2009) stated that “computer monitoring
823 includes tracking employees’ Internet use, recording network activities, and performing
824 security audits” (p. 80). Computer monitoring of activities appears to deter user computer

825 misuse because it increases the perceived chances of detection and punishment for such
826 behavior (D'Arcy et al., 2009; Straub, 1990). Computer monitoring directly influences
827 user computer misuse intention (D'Arcy & Hovav, 2009; Urbaczewski & Jessup, 2002).

828 Studies from criminology and sociology found that monitoring and surveillance
829 help deter users' computer misuse (Alm & McKee, 2006; D'Arcy et al., 2009). IS studies
830 suggest that computing monitoring can reduce user computer misuse while increasing
831 perceived certainty and severity of sanctions for computer misuse (D'Arcy et al., 2009;
832 Straub & Nance, 1990). Monitoring user computing activities is an active security
833 measure that enables organizations to detect and take appropriate actions on computer
834 misuse (D'Arcy & Hovav, 2009; D'Arcy et al., 2009). It seems that appropriate
835 monitoring practices increase an organization's ability to prevent intentional computer
836 misuse incidents that are likely to cause financial impact (D'Arcy et al., 2009). D'Arcy et
837 al. (2009) indicated that UAC-M has negative influence on users' computer misuse
838 intentions (D'Arcy et al., 2009). Torkzadeh and Lee (2003) found that CS plays an
839 important role towards CMI. Therefore, additional research is needed to better assess the
840 impacts of UAC-M on CS.

841

842 **User Awareness of Computer Sanctions**

843 In the context of UAC-S, general deterrence theory (GDT) theorizes that the
844 greater the certainty and severity of sanctions for banned acts the more users' intention
845 for committing such behavior is decreased (Gibbs, 1975). Sanction is the punishment for
846 breaking the cybersecurity rules set by the organization (D'Arcy et al., 2009). D'Arcy et
847 al. (2009) defined "certainty of sanctions as the probability of being punished" while

848 “severity of sanctions refers to the degree of punishment” (p. 82) in the context of
849 committing computer misuse. Researchers found that sanction fear helps to predict
850 criminal and illegal behaviors (D’Arcy et al., 2009). For example, hacking and stealing
851 intellectual property (e.g., program code) from organizations has more weight on sanction
852 fear than sharing password among co-workers.

853 The effectiveness of UAC-S on perceptions of punishment severity appears to be
854 important because perceived punishment severity is a deterrent to computer misuse
855 (D’Arcy et al., 2009). Sanctions derive from the GDT. This theory suggests that
856 perceived certainty, severity, and celerity of punishment affect people’s decision on CMI
857 (Pahnila, Siponen, & Mahmood, 2007). D’Arcy and Hovav (2009) suggested that the
858 strength of sanctions influences users’ ethical judgments and increases their perception of
859 the negative consequences of committing computer misuse. D’Arcy et al. (2009) found
860 that perceived severity of sanctions had a negative effect on user CMI, but perceived
861 certainty of sanctions did not have a negative impact. Hovav and D’Arcy (2012) found
862 that UAC-S may be significantly different across national cultures (e.g., U.S. vs. Korea).
863 Sanctions have been found to have no significant effect on CMI. This relationship was
864 well documented in literature as not supported (D’Arcy et al., 2009; Pahnila et al., 2007).
865 Therefore, UAC-S was not measured as it is well documented to not have significant
866 factor in the impact of UAC-S on CMI.

867

868 **Skills**

869 Skill is the ability to understand and make use of different intellectual abilities to
870 achieve the most appropriate action for the best result (Levy, 2005; Torkzadeh & Lee,

871 2003). Boyatzis and Kolb (1991) defined skill as a “combination of ability, knowledge
872 and experience that enables a person to do something well” (p. 280). The theory about
873 skill provides predictable development sequences in any field by integrating behavioral
874 and cognitive developmental concepts (Fischera, 1980; Udo, Bagchi, & Kirs, 2010).
875 Cognitive development is the skill structure called developmental levels (Fischera, 1980).
876 The transformation rules define the developmental levels by which a skill moves
877 gradually up from one level to another; on each developmental sequence the individual
878 controls a particular skill (Fischera, 1980). Skills are gradually transformed to produce
879 continuous behavioral changes (Fischera, 1980; Udo et al., 2010). Skills influence
880 people’s experience, attitude, and behavior (Udo et al., 2010). Skills increase a person’s
881 efficiency and positive behavior (Pryor, Cormier, Bateman, Matzke, & Karen, 2010).
882 Users’ skills can be developed and improved when they are aware and engaged in
883 adequate CCA initiatives (Pryor et al., 2010). It appears that cybersecurity
884 countermeasures awareness dimensions (UAS-P, UAS-T, & UAC-M) of users have a
885 positive influence on the three cybersecurity skills (CCS, CIS, & CAS) (Fischera, 1980;
886 Pryor et al., 2010; Udo et al., 2010). Torkzadeh and Lee (2003) found that cybersecurity
887 skills (CCS, CIS, & CAS) play a significant role in CMI. Therefore, it can be concluded
888 that additional research on CS is needed to better assess the impacts of CS on CMI.

889

890 **Information Technology Skills**

891 Torkzadeh and Lee (2003) claimed that the “effective use of information
892 technology (IT) is considered a major determinant of economic growth, competitive
893 advantage, productivity, and even personal competency” (p. 607). Benitez-Amado, Perez-

894 Arostegui, and Tamayo-Torres (2010) defined IT as the technological resources that
895 include “hardware, software, databases, applications and networks” (p. 89). IT skills
896 include the domains of management of information systems principles (Caputo 2010;
897 Havelka & Merhout, 2009). IT skill is the knowledge and ability to use computer
898 hardware, software, and procedures to develop specific computer applications
899 (Torkzadeh & Lee, 2003). Furthermore, the knowledge of computer programming
900 languages, use of databases, and computer programs such as antivirus programs are
901 considered to be part of IT skills (Havelka & Merhout, 2009; Torkzadeh & Lee, 2003).

902 There are two types of IT skills: a) soft IT skills and b) hard IT skills (Swinarski,
903 Parente, & Noce, 2010). The soft IT skills cover the IT business, IT project management,
904 and IT team domains, while the hard IT skills cover the computer software, hardware,
905 network, and security domains (Swinarski et al., 2010). IT skills for Information Systems
906 (IS) professionals can be said to be technical, technology management, and interpersonal
907 management skills (Havelka & Merhout, 2009). Havelka and Merhout (2009) developed
908 an IT skills framework consisting of hardware, software, business knowledge, business,
909 management, social, system knowledge, problem solving, and development methodology
910 skills. Havelka and Merhout (2009)’s IT skills framework is an important foundation in
911 the IT field. IT skills can be said to be the foundation of cybersecurity skills because
912 users need an appropriate level of IT skills to effectively learn and utilize their
913 cybersecurity skills (Havelka & Merhout, 2009; Lerouge, Newton, & Blanton, 2005).

914

915 **Cybersecurity Skills**

916 Cybersecurity skills (CS) correspond to the technical knowledge surrounding the
917 hardware and software required to implement information security (Lerouge et al., 2005).
918 According to Lerouge et al. (2005), information system users need an appropriate skill set
919 to effectively utilize cybersecurity functions and innovations. In their case study, Ramim
920 and Levy (2006) found that three of the main causes of system failure were due to users'
921 limited technology knowledge and skill, users' computer abuse, as well as the lack of
922 proper cybersecurity policies and procedures. Ramim and Levy (2006) claimed that the
923 majority of cybersecurity attacks come from insiders (e.g., employees), but unfortunately
924 most of the attention is given only to outsiders' (e.g., hackers) attacks.

925 One of the weakest and most difficult aspects of security governance is the user
926 CS management that consists of user awareness, education and training, ethical conduct,
927 trust, as well as privacy (Rezgui & Marks, 2008; Veiga & Eloff, 2007). The leading
928 reason is because user cybersecurity management deals with humans (e.g., computer
929 users). Besnard and Arief (2004) found that "humans obey least-effort rules because they
930 are cognitive machines that attempt to cheaply reach flexible objectives rather than to act
931 perfectly towards fixed targets" (p. 261). Having users enroll in cybersecurity training
932 and making them comply with the security guidelines could be a daunting process. Users
933 need to understand the importance of cybersecurity skills on both their personal and
934 professional levels (Rezgui & Marks, 2008). Computer users would be more interested in
935 taking the cybersecurity training if they knew the importance of CS to protect their home
936 and organization's computers from cybersecurity threats (Rezgui & Marks, 2008).

937 Users play an important role in contributing to cybersecurity solutions (Straub,
938 1990; Straub & Welke, 1998). The vast majority of IT managers and leaders
939 acknowledge that cybersecurity is important to the organization (Dinev & Hu, 2007;
940 Ruighaver et al., 2007). However, they are reluctant to support and fund cybersecurity
941 initiatives such as training due to the lack of understanding that cybersecurity is
942 everyone's responsibility; most senior management tend to rely on protective
943 technologies only (Dinev & Hu, 2007; Ruighaver et al., 2007). Users are often resistant to
944 security policies and bypass them, thus exposing their organizations to data loss and
945 cybercrime (Boss et al., 2009). It is worth noting that managers and employees also tend
946 to think of cybersecurity as a second priority compared with their own efficiency or
947 effectiveness matters because the latter have a direct and material impact on the outcome
948 of their work (Besnard & Arief, 2004). Boss et al. (2009) found that "despite the
949 prevalence of technical security measures, individual employees remain the key link –
950 and frequently the weakest link – in corporate defenses" (p.151).

951 Rezgui and Marks (2008) argued that the incompetence of users who
952 underestimate the dangers inherent in their actions represents one of the biggest computer
953 security problems. They stated that CCA should help overcome the users' cybersecurity
954 incompetence problem by helping them increase their cybersecurity skills. CCA is vital
955 in developing users' CS (Fischera, 1980; McCoy, 2010). Developing users CS will
956 change their cybersecurity behavior in positive ways (Boss et al., 2009; McCoy, 2010). In
957 fact, cybersecurity objectives cannot be met by technical and procedural protection only.
958 CS plays an important role in helping ensure effective users' cybersecurity awareness

959 which can aid in discouraging CMI (Besnard & Arief, 2004; Rezgui & Marks, 2008).
960 Therefore, more research is needed to better assess the impacts of CS on CMI.

961

962 **Cybersecurity Computing Skill**

963 Cybersecurity computing skills (CCS) correspond to the technical knowledge
964 surrounding the hardware and software required to implement information security
965 (Lerouge et al., 2005). CCS can be defined as the ability to use protective applications
966 (e.g., antivirus software) to protect computers, computer networks, and information
967 systems (Levy, 2005). According to Lerouge et al. (2005), information system users need
968 appropriate CCS set to effectively utilize cybersecurity functions and innovations.

969 One of the main causes of information security failure is due to users' limited
970 CCS (Ramim & Levy, 2006). Ramim and Levy (2006) stated that most of cybersecurity
971 attacks and abuse are done by employees from within the organization (e.g., computer
972 users), but most of the attention is given only to attacks and threats from outside.
973 Hacking, negative technologies (e.g., viruses), and theft are not the only threats to
974 information systems (Drevin et al., 2007). One of the biggest threats from users is human
975 error and misuse of computer assets (Drevin et al., 2007). Increasing users' CCS can help
976 reduce human error and misuse of computer assets (D'Arcy et al., 2009; Drevin et al.,
977 2007). It appears that CCS has a negative influence on users' computer misuse intention
978 (Drevin et al., 2007; Ramim & Levy, 2006). Thus, additional research on CCS is needed
979 to better assess the impacts of CCS on CMI.

980

981 **Cybersecurity Initiative Skill**

982 Initiative is a psychological transition that helps transform individual work roles
983 and responsibilities into desired outcomes (Rank, Pace, & Frese, 2004). Initiative skill is
984 a capacity to direct attention and effort over time toward a challenging goal (Dworkin,
985 Larson, & Hansen, 2003). Cybersecurity initiative skills (CIS) can be defined as the
986 ability to seek out and take advantage of security software (e.g., antivirus programs) and
987 best security practices (Levy, 2005). Activities such as cybersecurity training are
988 experiences in which users develop CIS by learning about how to make plans, overcome
989 obstacles, and achieve desired goals (Dworkin et al., 2003). Personal initiative is the
990 combination of proactive, self-starting, persisting behaviors that workers perform to
991 achieve their desired goals (Dreu & Nauta, 2009). A study of 300 individuals suggested
992 that individuals who held high complexity roles and jobs showed more personal initiative
993 (Dreu & Nauta, 2009).

994 It is unlikely for users to take any initiative toward cybersecurity if they don't
995 perceive it as useful (Davis, 1989). Albrechtsen (2007) claimed that a "user-involving
996 security awareness program approach is much more effective for influencing user
997 awareness behavior than general security awareness campaigns" (p. 283). According to
998 Cone, Irvine, Thompson, and Nguyen (2007), many organizations initiate a general
999 security campaign with hopes to educate and train users in cybersecurity. For example,
1000 general security campaigns are sending emails or notes to the users or publishing in the
1001 organizations' Intranet Website information about security. Unfortunately, general
1002 security campaigns are vastly ignored by most users (Cone et al., 2007). According to
1003 Cone et al. (2007), many forms of cybersecurity awareness initiatives fail because they

1004 are simple routines that do not require users to take initiatives and apply security
1005 concepts. Therefore, a carefully designed CCA program appears to be vital in an attempt
1006 to increase users' CIS (Cone et al., 2007).

1007 Technology savvy users don't automatically become cybersecurity savvy. In other
1008 words, users' CIS does not automatically increase with their knowledge of technology
1009 (Cronan, Foltz, & Jones, 2006). According to Cronan et al.'s (2006) study of 516
1010 students, participants who were more familiar with computers committed significantly
1011 more computer abuse. Aytes and Connolly (2004) claimed that it is unlikely that users
1012 will significantly change their cybersecurity behavior by just being provided information
1013 regarding computing risk. User's CIS on ethical conduct, trust, risk, and privacy may
1014 positively impact users' CMI (Rezgui & Marks, 2008; Veiga & Eloff, 2007).

1015

1016 **Cybersecurity Action Skill**

1017 Cybersecurity action skill (CAS) was defined as the ability to commit to
1018 objectives to meet security compliance (Levy, 2005). An action involves a collection of
1019 commitments that are applied to objectives (Fischera, 1980; Levy, 2005). Therefore,
1020 action must always be adapted to commitments (Fischera, 1980). For example, every
1021 time a user recognizes a familiar computer application, the action is adapted to the
1022 specific application (Fischera, 1980). Every time an action is carried out, even on the
1023 same objectives, it is usually done slightly differently (Fischera, 1980). Thus, the users
1024 can control the relevant action variations on objectives (Fischera, 1980). Action produces
1025 results, makes applications work, and causes events to occur (Korukonda, 1992). Thus,
1026 users' CAS is important for positive cybersecurity outcome (Korukonda, 1992).

1027 Action theory provides a three dimensional framework (Baum, Frese, & Baron,
 1028 2007). The three dimensions of the framework are sequence, structure, and focus (Baum
 1029 et al., 2007). Sequence reflects the path from goals to feedback, structure indicates the
 1030 level of regulation of action or skill to a meta-cognitive heuristic, and focus ranges from
 1031 task to self (Baum et al., 2007). Action theory leads to cognitive ability, which is
 1032 fundamental for entrepreneurs and employees to be able to take appropriate action (Baum
 1033 et al., 2007).

1034 According to Fishbein and Ajzen (1975) people's behavior is determined by their
 1035 behavioral intention to perform the action. The intention is determined by the person's
 1036 attitudes and subjective norms towards the behavior. The Theory of Reasoned Action
 1037 (TRA) developed by Fishbein and Ajzen (1975) is a model that finds its roots in the field
 1038 of social psychology. Fishbein and Ajzen's (1975) TRA defined the links between
 1039 attitudes, beliefs, norms, intentions, and behaviors of individuals; see Figure 2.

1040

1041 Figure 2. Theory of Reasoned Action (Fishbein & Ajzen, 1975)

1042 The key focus of the Theory of Reasoned Action (TRA) is on the causal
 1043 relationship between attitudes and behavioral intention; attitude influences behavioral
 1044 intention which affects a person's behavior (S. Lee, Yoon, & Kim, 2008). According to

1045 Fishbein (1980), reasoned action predicts that behavioral intent or action is caused by two
1046 main factors: attitudes and subjective norms. Similar to information integration theory,
1047 attitudes have two components. Fishbein and Ajzen (1975) called these the evaluation
1048 and strength of a belief. The second component influencing behavioral intent, subjective
1049 norms, also has two components. These components are normative beliefs (what one
1050 thinks others would want or expect him/her to do) and motivation to comply (how
1051 important is for one to do what he/she thinks others expect from him/her). Vallacher and
1052 Wegner (1987) suggested that “behavior dynamics are primary, with representations of
1053 action arising after the fact, or at best, concurrently with the action” (p. 3). Users’ attitude
1054 toward action or behavior influences intention, and intention is the main motivator of
1055 behavior (Fishbein & Ajzen, 1975). Therefore, TRA could be said to be the foundation of
1056 CAS (Fishbein, 1980; S. Lee et al., 2008). It appears that users’ attitude can be changed
1057 toward cybersecurity when CAS is increased (Fishbein, 1980; Korukonda, 1992). In
1058 addition, CAS can help decrease users’ CMI (Fishbein, 1980; Korukonda, 1992;
1059 Vallacher & Wegner 1987).

1060 Many organizations use positive technologies to monitor users’ actions (e.g.,
1061 browsing unsafe Internet sites) in the hopes of preventing them from wasting the
1062 company’s resources and downloading negative technologies (e.g., virus or worm)
1063 (Rezgui & Marks, 2008; Veiga & Eloff, 2007). It has been found that positive
1064 technologies don’t fully address all the cybersecurity risks since they can’t prevent users
1065 from engaging in risky activities (S. Lee et al., 2008; Rezgui & Marks, 2008; Veiga &
1066 Eloff, 2007). Numerous studies in psychology have been done on attitudes for predicting
1067 behavior and measuring the causal association between attitude and behavior (S. Lee et

1068 al., 2008). It appears that users' attitude and perceived social pressure, which is the
1069 predictor to behavioral intention, contribute to their actions (e.g., comply with security
1070 policies & procedures) (S. Lee et al., 2008). The main goal of implementing security
1071 policies and procedures is to secure the organizations' digital assets (Boss et al., 2009).
1072 Without an appropriate CCA program to educate the users' CAS, security policies and
1073 procedures can be meaningless (Boss et al., 2009). Ross (2006) suggested that CAS tends
1074 to keep users thinking and anticipating what if scenarios, thus preparing them to perform
1075 more adequately in an emergency without even thinking. CAS plays an important role on
1076 users' perception on CMI (Ross, 2006). Therefore, further research is needed to better
1077 assess the impacts of CAS on CMI.

1078

1079 **Summary of What is Known and Unknown in Research Literature**

1080 The ability to learn a skill can be observed to be closely related to computer self-
1081 efficacy (Compeau & Higgins, 1995; McCoy, 2010). Skill is the ability to understand and
1082 make use of different intellectual abilities to achieve the most appropriate action for the
1083 best result (Levy, 2005; Torkzadeh & Lee, 2003). Thus, cybersecurity skill is the ability
1084 to understand and make use of different intellectual abilities such as using cybersecurity
1085 tools (e.g., data encryption) to protect the organization and personal sensitive computer
1086 data (Levy, 2005; Rezgui & Marks, 2008; Torkzadeh & Lee, 2003; Veiga & Eloff, 2007).
1087 Unfortunately, users are often resistant to security policies and bypass them, thus
1088 exposing their organizations to data loss and cybercrime (Boss et al., 2009). In addition
1089 managers and employees tend to think of cybersecurity as a second priority compared
1090 with their own efficiency or effectiveness matters, because the latter have a direct and

1091 material impact on the outcome of their work (Besnard & Arief, 2004). Cybersecurity
1092 countermeasures awareness tends to keep users thinking and anticipating what if
1093 scenarios, thus preparing them to apply the learned cybersecurity skills when required
1094 (Ross, 2006). Therefore, UAS-P, UAS-T, UAC-M, UAC-S, CCS, CIS, and CAS appear
1095 to play an important role on CMI (Besnard & Arief, 2004; D'Arcy et al., 2009; Rezgui &
1096 Marks, 2008).

1097 It appears that CCA is inclusive to UAS-P, UAS-T, UAC-M, and UAC-S. UAS-P
1098 pertains to security policies, which are similar to societal laws, because they provide
1099 information on what constitutes unacceptable conduct, which increases the user's
1100 perceived threat of punishment for illegal behavior (D'Arcy et al., 2009; J. Lee & Lee
1101 2002). UAS-T pertains to security training programs, which reinforce acceptable
1102 computer usage guidelines and emphasize the potential consequences for computer
1103 misuse (D'Arcy et al., 2009). UAC-M pertains to computer monitoring, which is often
1104 used by organizations to gain compliance with rules and regulations (D'Arcy et al.,
1105 2009). Computer monitoring directly influences user computer misuse intention (D'Arcy
1106 & Hovav, 2009). UAC-S pertains to computer sanctions, which is similar to prohibition
1107 of specific behaviors (e.g., computer misuse) (D'Arcy & Hovav, 2009). The impact of
1108 UAC-S on perceptions of punishment severity is important because perceived
1109 punishment severity is a strong deterrent to computer misuse (D'Arcy et al., 2009).

1110 It seems that CS is inclusive to CCS, CIS, and CAS. CCS is the technical skill
1111 pertaining to the hardware and software knowledge that is required to implement proper
1112 cybersecurity (Lerouge et al., 2005). Information system users require an appropriate set
1113 of skills to employ cybersecurity technology functions more efficiently (Lerouge et al.,

1114 2005). CIS can be said to be the users' capacity to direct attention and effort over time
1115 toward a challenging goal such as implanting encryption to protect their sensitive data
1116 (Dworkin et al., 2003). CAS could be said to be the users' cybersecurity actions that
1117 produce positive cybersecurity results (Korukonda, 1992). Users that gain CCS, CIS, and
1118 CAS would be able to understand and implement cybersecurity technologies such as
1119 email encryption to secure their sensitive emails (Korukonda, 1992; Lerouge et al., 2005;
1120 Rank et al., 2004). Current literature appears to suggest that CSE, CCA, and CS can help
1121 reduce users' CMI (Korukonda, 1992; Lerouge et al., 2005; Rank et al., 2004); however,
1122 little attention has been given in research to provide empirical evidences for such
1123 interactions, while such validation in government organization appears to be highly
1124 needed.

1125

1126 **Contributions of this Study**

1127 The main contribution of this study is to the improvement of current research in
1128 cybersecurity in the public sector by adding to the body of knowledge concerning
1129 government agencies' user CSE, CCA, CS and their impact on CMI. The results of this
1130 study also provide information that could influence or support future strategies aimed at
1131 cybersecurity practitioners and IT managers justify funding for cybersecurity programs
1132 for end users' cybersecurity awareness and skill development (Besnard & Arief, 2004;
1133 Blanke, 2008; D'Arcy et al., 2009; Dinev et al., 2008; Rezgui & Marks, 2008; Torkzadeh
1134 & Lee, 2003; Veiga & Eloff, 2007; White House, 2009). In addition, this study
1135 contributes to the research community by providing its findings for further research.

1136 Another contribution of this study is that it helps to better understand various
1137 cybersecurity incidents that are generally caused by users. This research contributes to a
1138 better understanding of the causes of cybersecurity incidents attributable to users' CMI.
1139 Furthermore, this study contributes to more understanding of the necessary steps to help
1140 decrease users' CMI. Thus, the results of this study are in full agreement and supporting
1141 other IS literature that indicating that additional research is necessary to identify factors
1142 that influence individuals to engage in computer misuse activities (Blanke, 2008; D'Arcy
1143 et al., 2009; Dinev et al., 2008; Rezgui & Marks, 2008; Veiga & Eloff, 2007; White
1144 House, 2009).

Chapter 3

1149

Methodology

1150

1151 **Research Design**

1152 The main goal of this research study was to empirically test a predictive model on
1153 the impact of computer self-efficacy (CSE), cybersecurity countermeasures awareness
1154 (CCA), and cybersecurity skills (CS) on computer misuse intention (CMI) at government
1155 agencies. This study has assessed the role of users' CMI at a government agency. This
1156 field study used a Web-based survey instrument for data collection to test the
1157 relationships implied by Figure 1 and the research hypotheses put forth in Chapter 1. The
1158 survey was designed to capture respondents' perceptions of CSE, CCA, CS, and CMI. In
1159 this study, the participants were the computer users in a federal agency (Sekaran, 2003).
1160 Research design, sample, survey instrument and measures, validity and reliability, expert
1161 panel, pre-analysis data screening, as well as data analysis are presented in this chapter.

1162

1163 **Survey Instrument and Measures**

1164 Researchers need to demonstrate that their developed instruments are measuring
1165 what they are designed to be measuring (Straub, 1989). According to Straub (1989), an
1166 "instrument valid in content is one that has drawn representative questions from a
1167 universal pool" (p. 150). Selecting the right survey wording that approximates the level
1168 of understanding of the participants is important (Sekaran, 2003). According to

1169 Pinsonneault and Kraemer (1993), it is highly acceptable in research to collect data using
1170 surveys when independent and dependent constructs are well defined. Literature suggests
1171 that measures using a 7-point Likert scale appear to be more accurate than the 5-point
1172 Likert scale (D’Arcy et al., 2009; Levy & Green, 2009). Therefore, this study
1173 implemented a 7-point Likert scale following the scale established in literature for each
1174 of the measured constructs. This study used two different types of 7-point Likert scale to
1175 address different constructs. CSE, UAS-P, UAS-T, and UAC-M constructs were
1176 measured using 7-point Likert scale (1 = Strongly disagree to 7 = Strongly agree) in
1177 accordance to the validated constructs from literature (D’Arcy et al., 2009; Levy &
1178 Green, 2009) while CCS, CIS, and CAS constructs were measured with the 7-point Likert
1179 scale (1 = No skill or ability, 2 = I am now learning this skill, 3 = I can do this skill with
1180 some help from a supervisor, 4 = I am a competent performer in this area, 5 = I am an
1181 outstanding performer in this area, 6 = I am an exceptional performer in this area, and 7 =
1182 I am a leading performer in this area) in agreement with the validated constructs from
1183 literature pertaining to skill (Levy, 2005). According to Sekaran (2003), to ensure the
1184 content validity of the scales, the items selected must represent the concept about which
1185 generalizations are to be made. To check the validity of the survey, an expert panel was
1186 formed to include both academicians and practitioners. The expert panel reviewed the
1187 survey and provided recommendation(s) on wordings and clarity of the instrument.

1188 The measure of the CSE construct in Appendix A was adapted from Levy and
1189 Green (2009) who studied the role of CSE in acceptance of the U.S. Navy’s combat
1190 information system. The measures of the UAS-P, UAS-T, and UAC-M constructs in
1191 Appendix A were adapted from D’Arcy et al. (2009) who studied the role of user

1192 awareness of security countermeasures and its impact on information systems misuse.
 1193 Lastly, the measures of CCS, CIS, and CAS constructs in Appendix A are based on Levy
 1194 (2005)'s study on management skills comparison between online and on-campus Master
 1195 of Business Administration (MBA) programs and Torkzadeh and Lee (2003)'s study that
 1196 measured perceived user computing skills. The literature that serves as the foundation on
 1197 which the survey questions are adapted from is detailed in Table 1.

1198 Table 1. Survey question sources

Construct	No. of Items	No. of Items from Original Source	Original Scale Used	Survey Question Adapted From
Computer self-efficacy	3	3	7-point Likert scale	Levy & Green, 2009
User awareness of security policy	5	5	7-point Likert scale	D'Arcy et al., 2009
User awareness of security-training programs	5	5	7-point Likert scale	D'Arcy et al., 2009
User awareness of computer monitoring	6	6	7-point Likert scale	D'Arcy et al., 2009
Cybersecurity computing skill	6	12	5-point Likert scale	Torkzadeh & Lee, 2003
Cybersecurity initiative skill	6	6	7-point Likert scale	Levy, 2005
Cybersecurity action skill	6	6	7-point Likert scale	Levy, 2005
Computer misuse intentions	8	8	7-pint Likert	Hovav & D'Arcy, 2012

1199

1200 **Validity and Reliability**

1201 External validity threats, such as addressing the interaction of selection and
 1202 treatment, could be reduced when selecting groups with different racial, social,
 1203 geographical, age, gender, or personality (Creswell, 2005). In this study, participants
 1204 were from a government agency but were similar to the general user population. In order

1205 to provide representation of the general community, this study referenced to the data
 1206 collected from the federal employees as detailed in Table 2 (United States Census
 1207 Bureau, 2012).

1208 Participants were well diversified (e.g., racial, social, geographical, age, gender,
 1209 or personality) due to the nature of this government agency. The agency is located in the
 1210 heart of a large metropolitan area in the northeastern U.S. and its employee's origin is
 1211 from several different countries. It is almost impossible to find a group of participants to
 1212 represent every aspect of individualities (e.g., personality, diversity, or culture). This
 1213 study attempted to ensure that the study participants were closely representative of the
 1214 general agency population by sending the survey to every computer user in the agency
 1215 (Creswell, 2005).

1216 Table 2. The summary of characteristics of federal employees (United States Census
 1217 Bureau, 2012)
 1218

Federal Employees—Summary Characteristics: 1990 to 2008

[As of September 30. In percent, except as indicated. For civilian employees, excluding U.S. Postal Service employees]

Characteristics	1990	1995	2000	2003	2004	2005	2006	2007	2008
Average age (years) ¹	42.3	44.3	46.3	46.7	46.8	46.9	46.9	47.0	46.8
Average length of service (years)	13.4	15.5	17.1	16.8	16.6	16.4	16.3	16.1	15.5
Retirement eligible: ²

1219

1220 Construct validity is the assessment of the translation of theories into actual
 1221 measures or programs (Trochim, 2006). CSE construct is based on a well validated

1222 construct from Blanke (2008) that examined the contributions of CSE to the users' CMI.
1223 Blanke (2008)'s study was used as the groundwork to validate the impact of CSE toward
1224 CCA. UAS-P, UAS-T, and UAC-M constructs are based on a well validated construct
1225 from D'Arcy et al. (2009) who studied the role of users' awareness of security
1226 countermeasures and its impact on CMI. D'Arcy et al. (2009) provided the foundation to
1227 validate the influence of CAS on CS. CCS, CIS, and CAS constructs are based on the
1228 computing skill, initiative skill, and action skill that are validated constructs from
1229 Torkzadeh and Lee (2003)'s study that measured user computing skill, Levy (2005)'s
1230 study that measures skills in MBA programs, and Boyatzis and Kolb (1991)'s study on
1231 assessing individuality in learning skills. Their studies served as the groundwork to
1232 validate the impact of CS toward CMI. A social threat to construct validity exists, such as
1233 hypothesis guessing, evaluation apprehension, and experimenter expectation (Trochim,
1234 2006). Since the survey instrument has been developed from five different sources
1235 (Blanke, 2008; Boyatzis & Kolb, 1991; D'Arcy et al., 2009; Levy, 2005; Torkzadeh &
1236 Lee, 2003), it was submitted to an expert panel for a thorough review and evaluation.

1237

1238 *Expert Panel*

1239 The initial survey instrument was put through a review by an expert panel of
1240 cybersecurity professionals who evaluated the survey questions, the clarity of the
1241 questions, and the accuracy of the measurement instrument. The expert panel consisted of
1242 three prominent cybersecurity professors and five practitioners that intensely reviewed
1243 the survey instrument for validity. To ensure all scales were inputted in the same
1244 direction every survey question was reviewed prior to the data analysis (Levy, 2006). The

1245 expert panel members were asked to provide recommendations for modifications and
1246 essentially performed a thorough examination of the instrument's validity. The expert
1247 panel members were asked to (a) indicate their perception as to whether or not the
1248 individual items served to measure the constructs being evaluated, (b) recommend any
1249 additional items they believed could enhance the survey instrument, and (c) provide
1250 general comments on content and structure of the current survey instrument. The
1251 feedback from the expert panel was used to adjust the instrument as needed. In
1252 accordance with the approach of Straub (1989), adjustments included the removal of
1253 unnecessary items and the modification of questions, language, or layout of the
1254 instrument. The expert panel's feedback of the survey instrument was administered
1255 online over a couple of weeks using Google forms and surveys. Following the
1256 adjustments and testing, the finalized survey instrument that was used in this study was
1257 developed.

1258

1259 **Sample and Data Collection**

1260 In this study, participants were invited from the local and state transportation
1261 agency, the largest among the nation's bridge and tunnel toll authorities in terms of traffic
1262 volume. The local and state transportation agency serves more than a million people daily
1263 in a large metropolitan area in the northeastern U.S. As a constituent agency of the local
1264 and state transportation agency, its dual role is to operate bridges and tunnels while
1265 providing surplus toll revenues to help support public transit.

1266 This study targeted 500 participants with an anticipated response rate of 30%.
1267 According to Fowler (2009) the size of the sample has almost no impact on how well that

1268 sample is likely to describe the population. Fowler (2009) stated that “a sample of 150
1269 people will describe a population of 15,000 or 15 million with virtually the same degree
1270 of accuracy” (p. 44). Demographic information such as age, gender, job function,
1271 education level, length of working in the organization, as well as military status such as
1272 veteran were collected. The demographic information can be used to describe the sample
1273 characteristics in the research to test the representation of the data collection to the
1274 generalized study population (Sekaran 2003).

1275

1276 **Pre-analysis Data Screening**

1277 Pre-analysis data screening was performed before the data collection was
1278 analyzed in the Statistical Package for the Social Sciences® (SPSS). Pre-analysis data
1279 screening is important to ensure the accuracy of the collected data and to deal with the
1280 issues of response-set, missing data, and outliers (Levy, 2006). Accuracy of the collected
1281 data is critical since inaccurate data will result in invalid data analysis (Levy, 2006).
1282 Response-set is when a survey participant checks the same score for all the items. This
1283 can be addressed by eliminating the data from this participant from the final analysis
1284 (Blanke, 2008). Missing data can significantly impact the validity of the collected data
1285 (Blanke, 2008). To avoid missing data, the Web-based survey required all fields to be
1286 completed before submission. Lastly, Mahalanobis Distance was used to determine if any
1287 extreme cases, such as multivariate outliers existed and if the data should be included or
1288 eliminated from the data analysis (Blanke, 2008). According to Mertler and Vannetta
1289 (2001), an outlier can cause “a result to be insignificant when, without the outlier, it
1290 would have been significant” (p. 27). Thus, outlier cases were evaluated for removal prior

1291 to analyses. The survey was administered online over a few week period using Google
1292 forms.

1293

1294 **Data Analysis**

1295 Carefully selecting the right process of data analysis is important (Creswell,
1296 2005). This study used partial least square (PLS) to examine seven independent variables
1297 (CSE, UAS-P, UAS-T, UAC-M, CCS, CIS, & CAS) and their contributions on the
1298 dependent variable CMI. The PLS procedure has been gaining interest and use among IS
1299 researchers because of its ability to model latent constructs under conditions of non-
1300 normality and small to medium sample sizes (Compeau & Higgins, 1995). PLS is
1301 commonly recommended for predictive research models where the emphasis is on theory
1302 development (Chin, 1998). PLS employs a component based approach for estimation and
1303 has less restriction on sample size (Chin, 1998). PLS is suitable for analyzing complex
1304 models with latent variables (Chin, 1998). PLS is typically recommended in situations in
1305 which the sample size is small (Haenlein & Kaplan, 2004). Also, PLS was used to
1306 examine the contributions of the six control variables (i.e., age, gender, job function,
1307 education level, length of working in the organization, & military status such as veteran)
1308 on the dependent variable, CMI.

1309 This study has evaluated the major hypothesis on CSE, UAS-P, UAS-T, UAC-M,
1310 UAS-S, CCS, CIS, CAS and CMI. Hypothesis 1, CSE of users will show significant
1311 positive influence on the cybersecurity countermeasures awareness dimensions (UAS-P,
1312 UAS-T, & UAC-M). Hypothesis 2 (a, b, c, d), Cybersecurity countermeasures awareness
1313 dimensions (UAS-P, UAS-T, & UAC-M) of users will show significant positive

1314 influence on the three cybersecurity skills (CCS, CIS, & CAS). Hypothesis 3, the three
1315 cybersecurity skills (CCS, CIS, & CAS) of users will show significant negative influence
1316 on Computer Misuse Intention (CMI). Finally, Hypothesis 4 (a, b, c, d, e, f, & g), the six
1317 control variables (i.e., age, gender, job function, education level, length of working in the
1318 organization, as well as military status such as veteran) will show no significant influence
1319 on CMI. PLS was used to test the convergent and discriminant validity of the scales. In a
1320 confirmatory factor analysis (CFA) by PLS, convergent validity will be demonstrated
1321 when a measurement is loaded highly, its coefficient is above 0.60 or loaded significantly
1322 on the main factor, its t values are within the 0.05 level of their assigned construct (Gefen
1323 & Straub, 2005). In order to assess the reliability of the measurement items, the
1324 composite construct reliability coefficient was computed.

1325

1326 *Model Fit*

1327 IBM SPSS® and SmartPLS® statistical packages were used to perform the model
1328 fit testing based on Partial Least Square (PLS). According to Haenlein and Kaplan
1329 (2004), PLS should be an appropriate technique for model fit examination. The four
1330 hypotheses were tested using a model-fit analysis. Wetzels, Odekerken-Schröder, and
1331 Van-Oppen (2009) suggested a global fit measure (GoF) for PLS path modeling as a
1332 geometric mean of the average communality and average R^2 . They also indicated three
1333 cut-off points for GoF which are $GoF(\text{small}) = 0.1$, $GoF(\text{medium}) = 0.25$, and $GoF(\text{large})$
1334 $= 0.36$. As such, the GoF for the model was calculated by PLS in the means of the
1335 average communality and average R^2 .

1336 **Summary**

1337 This chapter provided an overview of the methodology that has been utilized to
1338 conduct this study. The population is described as working professionals at a government
1339 agency in the northeastern U.S. This chapter described the study that attempted to assess
1340 the role of user CSE, CCA, and CS as well as a set of six demographic variables toward
1341 CMI. A survey instrument was proposed based on validated prior measures. The study
1342 targeted 500 participants with an anticipated response rate of 30%. Data collection was
1343 outlined via the use of a Web-based survey instrument. The pre-analysis screening was
1344 performed before the data was collected (Levy, 2006). The collected data was analyzed in
1345 SPSS and PLS, while the GoF cut-of-points were proposed based on prior literature.

1350

Chapter 4

1351

Results

1352

1353 **Overview**

1354 This chapter details the data analysis and the results of this study. The chapter is
1355 organized in a similar way to chapter three and, as such, will include an analysis of the
1356 data collection process and the statistical methods used to analyze the data, and the
1357 overall results. First, the quantitative phase will be presented, which details the results of
1358 this study. This will be followed by the results of the pre-analysis data screening and then
1359 the results of the quantitative phase. The chapter will conclude with a summary of the
1360 results and the procedures used for the analysis.

1361 The main goal of this research study was to empirically test a predictive model
1362 measuring the impact of computer self-efficacy (CSE), cybersecurity countermeasures
1363 awareness (CCA), and cybersecurity skills (CS) on computer misuse intention (CMI) at
1364 government agencies, along with testing of a set of six control variables. The four
1365 specific research hypotheses addressed were:

1366 H1: Computer self-efficacy (CSE) of users will show significant positive
1367 influence on the cybersecurity countermeasures awareness dimensions (UAS-P,
1368 UAS-T, & UAC-M).

1369 H2a: User awareness of security policy (UAS-P) will show significant positive
1370 influence on the three cybersecurity skills (CCS, CIS, & CAS).

1371 H2b: User awareness of security-training programs (UAS-T) will show significant
1372 positive influence on the three cybersecurity skills (CCS, CIS, & CAS).

1373 H2c: User awareness of computer monitoring (UAC-M) will show significant
1374 positive influence on the three cybersecurity skills (CCS, CIS, & CAS).

1375 H3: The three cybersecurity skills (CCS, CIS, & CAS) of users will show
1376 significant negative influence on Computer Misuse Intention (CMI).

1377 H4a: Users' *age* will show no significant influence on Computer Misuse Intention
1378 (CMI).

1379 H4b: Users' *gender* will show no significant influence on Computer Misuse
1380 Intention (CMI).

1381 H4c: Users' *job function* will show no significant influence on Computer Misuse
1382 Intention (CMI).

1383 H4d: Users' *education level* will show no significant influence on Computer
1384 Misuse Intention (CMI).

1385 H4e: Users' *length of working in the organization* will show no significant
1386 influence on Computer Misuse Intention (CMI).

1387 H4f: Users' *military veteran status (i.e. 'yes' or 'no')* will show no significant
1388 influence on Computer Misuse Intention (CMI).

1389

1390 **Pre-Analysis Data Screening**

1391 There were 185 responses received from the survey respondents. Before the
1392 collected data could be analyzed, pre-analysis data screening had to be performed. Pre-
1393 analysis data screening was performed to detect irregularities or problems with the

1394 collected data. According to Levy (2006), pre-analysis data screening is performed to
1395 ensure the accuracy of the data collected, to deal with the issue of response set, to deal
1396 with missing data, and to deal with extreme cases or outliers. For this study, data
1397 accuracy was not an issue as the Web-based survey instrument was designed to allow
1398 only a single valid answer for each question. Additionally, data collected did not require
1399 any manual input as it was submitted directly into an online spreadsheet that then, was
1400 downloaded directly for the analyses. The issue of missing data was also not an issue for
1401 this study as the Web-based survey instrument was designed to prevent final submission
1402 until all items were completed. To address the issue of response-sets, a visual inspection
1403 of all responses was performed to identify cases that had the same response to all of the
1404 questions. Response-set bias is a factor that produces a particular pattern of responses that
1405 may not correctly correspond to the true state of affairs (Mangione, 1995). Kerlinger and
1406 Lee (2000) recommended the analysis of data for potential response-sets, and that
1407 researchers consider the elimination of any such sets from the research prior to data
1408 analysis. No response-set cases were found in the collected data.

1409 One of the main reasons for pre-analysis data screening was to deal with extreme
1410 cases (e.g., outliers). Stevens (2007) stated that an outlier is a data point that is usually
1411 very different from the rest of the data. In order to address multivariate extreme case(s),
1412 Mahalanobis Distance analysis was performed. There was one case (case # 115)
1413 identified using Mahalanobis Distance as a significant multivariate outlier. Therefore,
1414 case number 115 has been reviewed and removed from the analysis. Table 3 details the
1415 cases with multivariate extreme values that resulted from the Mahalanobis Distance
1416 analysis.

1417 Table 3. Mahalanobis distance extreme values (N=184)

			Case Number	CaseID	Value
Mahalanobis Distance	Highest	1	115	115	113.93522
		2	100	100	93.35203
		3	70	70	89.36936
		4	2	2	87.16059
		5	7	7	84.32366
	Lowest	1	93	93	7.99108
		2	8	8	14.58894
		3	153	153	15.13792
		4	59	59	15.17484
		5	29	29	15.21067

1418

1419

1420 *Demographic Analysis*

1421 After completion of the pre-analysis data screening, 184 responses remained for
1422 analysis of which 48 or 26.1% were completed by females and 136 or 73.9% were
1423 completed by males. Analysis of the respondents' age indicated that 11 or 6% were
1424 20 to 29 years of age, 28 or 15.2 % of respondents were between the ages of 30 to 39, 70
1425 or 38% of respondents were between the ages of 40 to 49, 54 or 29.3% of respondents
1426 were between the ages of 50 to 59, and 21 or 11.4% of respondents were 60 and over. 27
1427 or 14.7% of respondents were administrator staff, 67 or 36.4% were managerial, 33 or
1428 17.9% were officers, 23 or 12.5% were people working in operations, three or 1.6% were
1429 security operators, 18 or 9.8% were IT people, 11 or 6% were professional staff, and the
1430 remaining two or 1.1% were others (e.g., College interns). Among the respondents, two
1431 or 1.1% were with the organization under one year, 24 or 13% were with the organization
1432 between 1- to 5-years, 35 or 19% were with the organization between 6- to 10 years, 52
1433 or 28.3% were with the organization between 11 to 15 years, 23 or 12.5% were with the
1434 organization between 16 to 20 years, 31 or 16.8% were with the organization between 21

1435 to 25 years, 4 or 2.2% were with the organization between 26 to 30 years, and 13 or 7.1%
 1436 were with the organization for over 30 years. Approximately 50% (90 or 48%) had
 1437 bachelor's degree. Also, 35 or 19% were veterans. Details on the demographics of the
 1438 population are presented in Table 4.

1441 *Validity and Reliability Analyses*

1442 Model evaluation involves estimation of internal consistency, convergent

1443 discriminant validity tests to achieve construct validity, as well as reliability (Chin &

1444 Todd, 1995). Construct reliability is calculated by Cronbach's Alpha and composite

1445 reliability (Fornell & Lacker, 1981). The Cronbach's Alpha coefficients for all constructs

1446 in this study were greater than the threshold of 0.7 indicating very strong reliability for

1447 the constructs measured. The composite reliability implicitly assumes that each indicator

1448 has the same weight and it relies on actual factor loadings, which can be considered as

1449 the best measure for internal consistency (Fornell & Lacker, 1981). The composite

1450 reliability should be greater than 0.7 to reflect internal consistency. According to Table 5,

1451 all multi-item constructs measured have demonstrated very high composite reliability

1452 coefficients that are greater than 0.7, further validates the high reliability of all constructs

1453 measured. Convergence validity was assessed using average variance extracted (AVE).

1454 Fornell and Lacker (1981) suggested that greater than 0.5 is standard. All AVE were

1455 above 0.5 with exception of CMI being 0.434. AVE can be used to evaluate the

1456 discriminant validity. The value obtained from each construct should be greater than the

1457 variance divided between that construct and other variables in the model (Chin, 1998;

1458 Fornell & Lacker, 1981). Discriminant validity can be obtained by observing whether

1459 correlations between variables are less than the square of average variance extracted.

1460 Table 6 shows that the squared value of average variance extracted for each construct is
 1461 larger than the correlations in the same column (Chin, 1998; Fornell & Lacker, 1981).

1462

1465

1466 T-value has been obtained by running bootstrapping in SmartPLS. Given the data
 1467 obtained, some adjustments in the proposed model path testing had to be taken into
 1468 consideration for the model testing to reflect a viable model, which is slightly different
 1469 than the one originally proposed. However, majority of the model path proposed were
 1470 included in the tested model. T-value is used to identify the significance level of each
 1471 path in the model. Based on this study with 184 degrees of freedom (df), T-values greater
 1472 than 1.960 are significant at a p-value less than 0.05, T-values greater than 2.576 are
 1473 significant at a p-value less than 0.01, and T-values greater than 3.291 are significant at a
 1474 p-value less than 0.001 (Gravetter & Wallnau, 2009). Table 7 shows the coefficient and
 1475 T-value of each set of constructs path. A correlation coefficient is a number between -1
 1476 and 1, which measures the degree to which two variables are linearly related. If there is a
 1477 perfect linear relationship with positive slope between the two variables, then it is a
 1478 correlation coefficient of 1; if there is positive correlation, whenever one variable has a
 1479 high (low) value, so does the other. If there is a perfect linear relationship with negative
 1480 slope between the two variables, then it is a correlation coefficient of -1; if there is
 1481 negative correlation, whenever one variable has a high (low) value; the other has a low
 1482 (high) value. A correlation coefficient of 1 means that the two numbers are perfectly
 1483 correlated while a correlation coefficient of -1 means that the numbers are perfectly
 1484 inversely correlated. A correlation coefficient of zero means that there is no linear
 1485 relationship between the variables (Chin & Todd, 1995; Fornell & Larcker, 1981).

1486 Table 7. Path coefficients significance (N=184)

Path	Coefficients	T Statistics	Significant
CAS -> CMI	-0.152762	1.118844	p = 0.265 Not supported

1487 *p<.05 (two-tailed tests).

1488 **p<.001 (two-tailed tests).

1489

1490 PLS was used to address the four hypotheses. Results of the standardized PLS
 1491 path coefficients model for this study is presented in Figure 3. The numbers noted on the
 1492 arrows in the model represent the rounded path coefficient to the nearest hundredths
 1493 value, where results indicated that five out of the construct 12 path coefficients (not
 1494 including the demographic indicators) (CIS → CMI, CSE → CSS, UAC-M → CCS,
 1495 UAC-M → CMI, & UAS-P → CAS) were significant at least at the p value of .05 level
 1496 or greater (p<.001). The rest of the model paths (CSS → CMI, CAS → CMI, CSE →
 1497 CMI, UAS-P → CCS, UAS-P → CIS, UAS-P → CMI, UAS-T → CMI, Age → CMI,
 1498 Gender → CMI, Job Function → CMI, Education → CMI, Work Length → CMI, &
 1499 Veteran Status → CMI) that were tested indicated path coefficients with non-significant
 1500 p-values. Results of the R-squared (R^2) values are indicated below the given constructs
 1501 where R^2 is applicable. R-squared (R^2) on CMI is 0.296 or nearly 0.30, an indicated
 1502 acceptable model fit.

1503

1504 Figure 3. Results of the PLS analysis (N=184)

1505 The results of the PLS model showed that UAC-M and CIS were significant
 1506 contributors ($p < .05$) to CMI. UAC-M was also found to be a significant contributor (p
 1507 $< .05$) to CCS. UAS-P was found to be a significant contributor ($p < .05$) to CAS. CSE
 1508 made a significant contribution ($p < .001$) to CCS while it did not show significant
 1509 contribution to CMI.

1510 While this study found that CSE had no influence on CMI, which appears to be
 1511 in support by prior research by D'Arcy and Hovav (2009) who found that CSE had also
 1512 no effect on misuse intention. However, it might be that the relationship between CSE
 1513 and CMI is just not linear. That is, those users with very low CSE are likely to engage in
 1514 misuse unintentionally or out of ignorance, while users with very high CSE are likely to
 1515 engage in misuse because they believe they can circumvent the system successfully and

1516 get away with it. As such additional research should be done on assessing such potential
1517 hyperbolic relations between the two constructs of CSE and CMI.

1518 The mean scores of the CMI and CSE were obtained for the 184 records (see
1519 Figure 4). The findings show that by-in-large, only seven cases out of the total of 184
1520 cases were CMI high, meaning that the majority (nearly 97%) of the respondents were
1521 ethical as their CMI was low. The most important finding is that majority (nearly 93%) of
1522 the participants had a high CSE while at the same time had a low CMI. This makes
1523 evident that there is a strong association between high CSE and low CMI. This suggests
1524 that, by-in-large, users with higher CSE have lower CMI, while such relationship may not
1525 be linear in nature and therefore, the low coefficient and T-value (i.e. high p-value)
1526 observed in this study. Phelps (2005) found that users with higher CSE were more
1527 effective at implementing system security. Crossler and Belanger (2006) stated that a
1528 user's level of CSE directly impacted his or her use of security tools. The plotting of the
1529 taxonomy of the mean scores of CMI and CSE as a 2x2 matrix summary is presented in
1530 Table 8. This study considered CSE and CMI < 4 to be note as "Low" and 4 > to be
1531 "High".

1532 Table 8. CMI mean and CSE mean (N=184)

<u>Item</u>	<u>Cases</u>

1542

Similar to the CSE to CMI path that suggested the case of the few high-CSE and high-CMI computer savvy users (e.g., users with high CCS), they feel that they can overcome the computer monitoring capabilities of their organizations and that they are less likely to be caught when engaging in computer misuse. Perhaps users with high CCS (e.g., hackers) might be more likely to engage in misuse because they believe they can circumvent the system successfully and get away with it. Therefore, someone with higher CCS could also appear to have higher CMI.

Summary

1543

1544

1545

1546

1547

Chapter 4 reported on the results of all data analysis performed in order to answer the four hypotheses set in this study. In this chapter, the results of the contribution of CSE, CCA, and CS to CMI, as measured by the weight of their contribution to the prediction of CMI, are presented. Prior to the statistical analyses, pre-analysis data screening was performed to ensure the accuracy of the data collected. Following this

1548 screening, Cronbach's Alpha reliability tests were conducted for each construct to
1549 determine how well the items for each scale were internally consistent with one another.
1550 The results demonstrated high reliability for all constructs measured. In order to
1551 determine the representativeness of the sample, demographic data were requested from
1552 the survey participants. The distribution of the data collected appeared to be
1553 representative of the population of government employees.

1554 PLS was used to address the four hypotheses and test the model fit. Given the
1555 type of data collected and the amount of constructs measured, modifications were needed
1556 from the original model proposed in order to test the path coefficients among the
1557 constructs measured. The results of the PLS model showed that UAC-M and CIS were
1558 significant contributors ($p < .05$) to CMI. UAC-M was also found as a significant
1559 contributor ($p < .05$) to CCS. UAS-P was found as a significant contributor ($p < .05$) to
1560 CAS. CSE demonstrated the most significant contribution ($p < .001$) to CCS while it
1561 didn't show significant contribution to CMI.

Chapter 5

1566 Conclusions, Implications, Recommendations, and Summary

1567

1568 **Conclusions**

1569 This chapter begins with conclusions drawn from the results of this study. The
1570 main goal and hypotheses investigated are detailed next, and the implications of the study
1571 are discussed. Moreover, contributions of this study to the body of knowledge are
1572 presented followed by the limitations of this study. The chapter ends with
1573 recommendations for future research and a summary of this study.

1574 The main goal of this research study was to empirically test a predictive model on
1575 the impact of computer self-efficacy (CSE), cybersecurity countermeasures awareness
1576 (CCA), and cybersecurity skills (CS) on computer misuse intention (CMI) at government
1577 agencies along with a set of six demographic indicators. The population of this study was
1578 working professionals from a government agency located in northeastern U.S. The
1579 original projected response rate was seeking 30% out of 500 potential participants, while
1580 the actual survey response rate obtained was nearly 37%, 184 usable records.

1581 The first specific goal of this study was to empirically assess CSE and its
1582 contribution to CCA (UAS-P, UAS-T, & UAS-M) dimensions. The results of the PLS
1583 model indicated that CSE did not make any significant contribution to CCA. While not
1584 originally hypothesized, CSE demonstrated a significant contribution ($p < .001$) to CCS.

1585 The second goal of this study was to empirically assess CCA (UAS-P, UAS-T, &
1586 UAS-M) dimensions and its contribution to CS (CCS, CIS, & CAS). Based on the PLS
1587 model, UAS-P demonstrated a significant contribution ($p < .05$) to CAS. UAC-M was
1588 found to be a significant contributor ($p < .05$) to CCS. Interestingly, UAS-T did not make
1589 any significant contribution to any of the CS dimensions.

1590 The third goal of this study was to empirically assess CS (CCS, CIS, & CAS) and
1591 its contribution to CMI. The PLS model revealed that UAC-M and CIS were found to be
1592 significant contributors ($p < .05$) to CMI. CCS was found to demonstrate limited
1593 significant contribution ($p = 0.052$) to CMI.

1594 The fourth goal of this study was to empirically assess to empirically assess age,
1595 gender, job function (i.e., job title), education level, length of working in the
1596 organization, and military status (e.g., veteran) and their contributions to CMI. The PLS
1597 model showed that most of the demographic latent variables didn't show any significance
1598 except for age, which showed limited significant difference ($p = 0.087$) to CMI.

1599 The last goal was to empirically assess the fit of the model by using CSE, CCA
1600 (i.e., UAS-P, UAS-T, & UAC-M), CS (i.e., CCS, CIS, & CAS), CMI, and control
1601 variables. The PLS model presented the results of the study (see Figure 3). The results
1602 indicated that UAC-M and CIS made significant contributions ($p < .05$) to CMI. UAC-M
1603 showed significant contribution ($p < .05$) to CCS. UAS-P indicated significant
1604 contribution ($p < .05$) to CAS. Lastly, CSE demonstrated a significant contribution ($p <$
1605 $.001$) to CCS while it did not show significant contribution to CMI.

1606 The purpose of our study was to assess the role of user computer self-efficacy,
1607 cybersecurity countermeasures awareness, and cybersecurity skills toward computer

1608 misuse intention at government agencies. The results showed that UAS-P demonstrated a
1609 significant contribution to CAS and UAC-M demonstrated a significant contributor to
1610 CCS. This finding is consistent with the recommendations of IS security advocates who
1611 contend that security countermeasures awareness are important when it comes to
1612 cybersecurity skills. One area that did not demonstrate significant contribution from CCA
1613 was CIS. This suggests that, in the context of the data collected in this study, CCA
1614 increases users' CCS and CAS while it doesn't have a significant contribution on users'
1615 CIS. However, additional research maybe needed to further investigate these findings.

1616 CSE showed significant contribution to CCS while it did not show significant
1617 contribution to CMI. The results suggest that while the CSE to CCS path is in accordance
1618 with the recommendations of IS security advocates who contend that computer self-
1619 efficacy by employees are valid to enhance as they also significantly measure their
1620 security countermeasures awareness. The non-significant result found in this study of
1621 CSE to CMI path suggests that in the case of the few high-CSE and high-CMI computer
1622 savvy users, they feel that they can overcome the computer monitoring capabilities of
1623 their organizations and that they are less likely to be caught when engaging in computer
1624 misuse. Computer savvy users may also know that security personnel cannot actively
1625 monitor all computing activities, even though such activities might get automatically
1626 logged and recorded by monitoring technologies. While these issues appear to be valid
1627 for the high-CSE and high-CMI computer users, the results indicated that 96% of the
1628 participants demonstrated, by-in-large, to be ethical with varied CSE, but a low CMI.

1629 UAC-M and CIS were significant contributors to CMI. This is consistent with the
1630 recommendations of IS security advocates and researchers. CCS showed limited

1631 significant contribution ($p = 0.052$) to CMI. Contrary to expectations, UAS-T did not
1632 make any significant contribution to any of the CS dimensions or CMI. This finding was
1633 surprising since literature suggested that UAS-T should have a significant contribution to
1634 CS dimensions. One possible explanation for these results could be the relatively high
1635 age of the survey participants. In this study, majority of the participants were in the 40
1636 years old and older age group, representing 78.7% of the participants. In addition, age
1637 was the only control variable that demonstrated limited significant contribution ($p =$
1638 0.087) to CMI. As such, the impact of UAS-T on CS and CMI should be further
1639 investigated with different professional computer users to investigate if such results are
1640 specific for the data collected in this study or indeed due to the age issue.

1641

1642 **Study Implications**

1643 This research study has a number of implications for the existing body of
1644 knowledge in the areas of IS and cybersecurity within government agencies. A prediction
1645 model was developed with CSE, CCA, and CS in an attempt to validate a model to
1646 predict employees' CMI in a government agency. These independent variables were
1647 selected for the model based on the literature search that was conducted. There are two
1648 key contributions that this study makes to IS and cybersecurity research. The first one is
1649 to develop and empirically validate a model for predicting government employees' CMI.
1650 While significant number of information security studies have been conducted using
1651 college students as participants, the second key contribution of this study is the
1652 investigation of the most significant constructs that contribute to professional employees'
1653 (non-students) CMI in government agency environment.

1654 This investigation also contributes to the IS and cybersecurity practice in that it
1655 provides valuable information that can be used in government agencies in an effort to
1656 significantly reduce computer user's misuse and, therefore, increase productivity and
1657 effectiveness. With computer abuse being reported in more than half of the business
1658 environments surveyed by the Computer Security Institute (CSI), computer user's misuse
1659 is problematic and continues to significantly increase. With this investigation and the
1660 existing body of knowledge, government agencies may be better positioned to understand
1661 and reduce computer users' misuse, starting with reducing their CMI.

1662

1663 **Study Limitations**

1664 Like any other empirical research, this study also had several limitations. Three
1665 limitations were identified for this study. First, the study was comprised of working
1666 professionals at a single local government agency located in the northeastern U.S. Non-
1667 government organizations and government agencies of other states or countries were not
1668 covered in this study. Second, the survey for this study was completed within a four-week
1669 timeframe. Leonard and Cronan (2005) stated that a longitudinal study is needed as CSE,
1670 CCA, and CS influence may shift over time. Organizations must periodically reassess
1671 their employee's CSE, CCA, and CS and adjust the constructs that influence CMI
1672 (Leonard & Cronan, 2005). Third, self-reported CMI were measured instead of actual
1673 behaviors. Prior research indicates there is a reluctance of survey participants to report
1674 computer misuse (Foltz, 2004; Parker, 1998; Straub, 1990). While there is a significant
1675 body of research in IS (Ajzen, 1975; Davis, Bagozzi, & Warshaw, 1989) supporting
1676 intention as a predictor of actual behavior, actual behavior could be tracked by system

1677 monitoring tools instead of self-reported CMI. While actual misuse behaviors are
1678 difficult to measure, it is still measure that needs to be done by future work.

1679 User awareness of computer sanctions (UAC-S) was initially included in this
1680 study, but it was removed due to some survey issues. The agency was concerned about
1681 the questions asked in UAC-S that might not comply with the agency's strict union rules.
1682 Another issue was that the expert panel reviewing the survey were concerned that the
1683 overall instrument was too long. The survey had 51 questions not including the UAC-S'
1684 six questions. Therefore, it was decided to rely on D'Arcy et al. (2009), Hovav and
1685 D'Arcy (2012), as well as Pahnla et al. (2007) research on the role of UAC-S in CMI.
1686 They found that perceived severity of sanctions was associated with reduced CMI, but
1687 perceived certainty of sanctions was not a significant predictor of CMI. In addition, they
1688 also stated that UAC-S may be significantly different across national cultures (e.g., U.S.
1689 vs. Korea). Additional work may investigate the role of UAC-S, if possible, in CMI.

1690 The R-squared (R^2) of the latent variables on CMI was found to be 0.296 or
1691 nearly 30%. Wetzels et al., (2009) suggested a global fit measure (GoF) for PLS path
1692 modeling as a geometric mean of the average communality and average R^2 . They
1693 indicated three cut-off points for GoF which are $\text{GoF}(\text{small}) = 0.1$, $\text{GoF}(\text{medium}) = 0.25$,
1694 and $\text{GoF}(\text{large}) = 0.36$. This study's R-squared (R^2) fits within the $\text{GoF}(\text{medium}) = 0.25$
1695 and $\text{GoF}(\text{large}) = 0.36$, while a higher R^2 might have been able to demonstrate more
1696 significant results, thus, additional work is needed to re-validate the model proposed on
1697 another group of participants and in other more diverse organizations.

1698

1699 **Recommendations for Future Research**

1700 Many areas of future research were identified as a result of this work. This study
1701 investigated working professionals at a single local government agency. This study could
1702 be replicated at another government agency in another part of the country or level (e.g.,
1703 federal, state, or local government agency). In addition, this study can be also replicated
1704 in a private sector business environment as compared to a government agency. Future
1705 research could also be completed by incorporating and measuring user awareness of
1706 computer sanctions (UAC-S) and its role in reducing users' CMI in organizations.
1707 Research of system monitoring tools could also be completed to determine the percentage
1708 of computer use in government agencies that is non-work related (i.e. cyber-slacking) and
1709 test for various security countermeasures that could reduce the nonproductive work in the
1710 agency. Finally, as noted in the results section, future research is recommended to assess
1711 the potential hyperbolic relations between CSE and CMI constructs to better understand
1712 their non-linear relationship.

1713

1714 **Summary**

1715 This dissertation investigation addressed the problem of computer misuse
1716 intention (CMI) by employees in a government agency, which contributes to
1717 cybersecurity vulnerabilities. While computer technology is generally intended to
1718 increase employee productivity and effectiveness, that same computer technology may be
1719 used in negative ways that reduce productivity and increase cybersecurity vulnerabilities.
1720 Computer users play a large role in information security (Veiga & Eloff, 2007). Users are
1721 one of the weakest links in the information systems security chain because many users
1722 appear to have limited or no cybersecurity awareness and skills (Albrechtsen, 2007;

1723 Clifford, 2008). Many users are complacent with potential computer security risks when
1724 protective technologies (e.g., antivirus software) are not used or installed in their
1725 computer. They are willing to accept the security risks rather than addressing them due to
1726 the nuisances caused by security measures and cost (Dinev et al., 2008). Most users are
1727 not aware of the importance of protecting computer information systems, and this lack of
1728 awareness is reflected in their negligence in cybersecurity practices (Thomson & Solms,
1729 2005). D'Arcy and Hovav (2009) as well as Straub (1986) have suggested that additional
1730 research investigating the factors that influence CMI is needed. After completing a
1731 comprehensive literature review, three constructs were identified as possible factors that
1732 may contribute to employee CMI.

1733 The first construct identified in the literature as a possible contributor to CMI was
1734 computer self-efficacy (CSE). Bandura (1977), Compeau and Higgins (1995), Fischera
1735 (1980), Levy and Green (2009), Marakas et al. (1998), McCoy (2010), and Piccoli et al.
1736 (2001) suggested that CSE is a construct that contributes to CMI. Therefore, the
1737 contribution of CSE to employee CMI in government agency was investigated.

1738 The second construct identified in the literature as a possible contributor to CMI
1739 was cybersecurity countermeasures awareness (CCA). Additional research was suggested
1740 by Boss et al. (2009), D'Arcy et al. (2009), Lee and Lee (2002), Straub (1990), Straub
1741 and Welke (1998), Torkzadeh and Lee (2003), Wybo and Straub (1989), as well as
1742 Urbaczewski and Jessup (2002) to the contribution of UAS-P in reducing employee CMI.
1743 Thus, the contribution of CCA to employee CMI in government agency was also
1744 investigated.

1745 The third construct identified in the literature as a possible contributor to CMI
1746 was cybersecurity skills (CS). Albrechtsen (2007), Aytes and Connolly (2004), Cone et
1747 al. (2007), Cronan et al. (2006), Drevin et al. (2007), as well as Ramim and Levy (2006)
1748 suggested that CS is a factor that contributes to CMI. Hence, the contribution of CS to
1749 employee CMI in government agency was investigated.

1750 A predictive model was designed to assess employees' CMI in government
1751 agencies based on the contribution of CSE, CCA, and CS, as measured by their
1752 contribution to CMI. The four specific hypotheses addressed were:

1753 H1: Computer self-efficacy (CSE) of users will show significant positive
1754 influence on the cybersecurity countermeasures awareness dimensions (UAS-P,
1755 UAS-T, & UAC-M).

1756 H2a: User awareness of security policy (UAS-P) will show significant positive
1757 influence on the three cybersecurity skills (CCS, CIS, & CAS).

1758 H2b: User awareness of security-training programs (UAS-T) will show significant
1759 positive influence on the three cybersecurity skills (CCS, CIS, & CAS).

1760 H2c: User awareness of computer monitoring (UAC-M) will show significant
1761 positive influence on the three cybersecurity skills (CCS, CIS, & CAS).

1762 H3: The three cybersecurity skills (CCS, CIS, & CAS) of users will show
1763 significant negative influence on Computer Misuse Intention (CMI).

1764 H4a: Users' *age* will show no significant influence on Computer Misuse Intention
1765 (CMI).

1766 H4b: Users' *gender* will show no significant influence on Computer Misuse
1767 Intention (CMI).

1768 H4c: Users' *job function* will show no significant influence on Computer Misuse
1769 Intention (CMI).

1770 H4d: Users' *education level* will show no significant influence on Computer
1771 Misuse Intention (CMI).

1772 H4e: Users' *length of working in the organization* will show no significant
1773 influence on Computer Misuse Intention (CMI).

1774 H4f: Users' *military veteran status (i.e. 'yes' or 'no')* will show no significant
1775 influence on Computer Misuse Intention (CMI).

1776 To address the specific hypotheses above, a survey instrument was developed by
1777 using previously validated survey items from the following research pool: D'Arcy et al.
1778 (2009), Levy and Green (2009), Levy, (2005), Hovav and D'Arcy (2012), as well as
1779 Torkzadeh and Lee (2003). CSE was measured using a validated three-item instrument
1780 developed by Levy and Green (2009). UAS-T and UAS-P were measured by utilizing the
1781 five validated survey items developed by D'Arcy et al. (2009). UAC-M was measured by
1782 using the six validated survey items developed by D'Arcy et al. (2009). CCS was
1783 measured by utilizing the six validated survey items developed by Torkzadeh and Lee
1784 (2003). CIS and CAS were measured by using the six validated survey items developed
1785 Levy (2005). CMI was measured using a validated eight-item instrument developed by
1786 Hovav and D'Arcy (2012). The demographics were measured by using validated survey
1787 items recommended by the expert panel.

1788 A conceptual research model was proposed (see Figure 1). Partial Least Square
1789 (PLS) was utilized to test predictive power. It was predicted that CSE, CCA, and CS
1790 would have a significant ($p < .05$) impact on user's CMI. The results demonstrated that

1791 UAC-M and CIS were significant contributor ($p < .05$) to CMI. CSE demonstrated a
1792 significant contribution ($p < .001$) to CCS while it did not show significant contribution
1793 to CMI.

1794 Following the analyses, the results and conclusions were discussed. This study's
1795 implication and limitations were identified and discussed. Recommendations for future
1796 research were outlined to build on this research and add to the existing body of
1797 knowledge.

APPENDIX A

Survey Instrument

Please respond to each of the following statements.

Computer Self-Efficacy

A1. I am comfortable working with computers. *

1 2 3 4 5 6 7

Strongly disagree Strongly agree

A2. If I am given some training, I can learn to use most computer programs. *

1 2 3 4 5 6 7

Strongly disagree Strongly agree

A3. I can learn to use most computer programs just by reading the manuals and help. *

1 2 3 4 5 6 7

Strongly disagree Strongly agree

1807
1808

End-User Awareness of Security Policies

B1. My organization has specific guidelines that describe acceptable use of email. *

1 2 3 4 5 6 7

Strongly disagree Strongly agree

B2. My organization has established rules of behavior for use of computer resources. *

1 2 3 4 5 6 7

Strongly disagree Strongly agree

B3. My organization has a formal policy that forbids employees from accessing computer systems that they are not authorized to use. *

1 2 3 4 5 6 7

Strongly disagree Strongly agree

B4. My organization has specific guidelines that describe acceptable use of computer passwords. *

1 2 3 4 5 6 7

Strongly disagree Strongly agree

B5. My organization has specific guidelines that govern what employees are allowed to do with their computers. *

1 2 3 4 5 6 7

Strongly disagree Strongly agree

1809

End-User Awareness of Security-Training Programs

C1. My organization provides training to help employees improve their awareness of computer and information security issues. *

1 2 3 4 5 6 7

Strongly disagree Strongly agree

C2. My organization provides employees with education on computer software copyright laws. *

1 2 3 4 5 6 7

Strongly disagree Strongly agree

C3. In my organization, employees are briefed on the consequences of modifying computerized data in an unauthorized way. *

1 2 3 4 5 6 7

Strongly disagree Strongly agree

C4. My organization educates employees on their computer security responsibilities. *

1 2 3 4 5 6 7

Strongly disagree Strongly agree

C5. In my organization, employees are briefed on the consequences of accessing computer systems that they are not authorized to use. *

1 2 3 4 5 6 7

Strongly disagree Strongly agree

1810
1811

End-User Awareness of Computer Monitoring

D1. I believe that my organization monitors any modification or altering of computerized data by employees. *

1 2 3 4 5 6 7

Strongly disagree Strongly agree

D2. I believe that employee computing activities are monitored by my organization. *

1 2 3 4 5 6 7

Strongly disagree Strongly agree

D3. I believe that my organization monitors computing activities to ensure that employees are performing only explicitly authorized tasks. *

1 2 3 4 5 6 7

Strongly disagree Strongly agree

D4. I believe that my organization reviews logs of employees' computing activities on a regular basis. *

1 2 3 4 5 6 7

Strongly disagree Strongly agree

D5. I believe that my organization conducts periodic audits to detect the use of unauthorized software on its computers. *

1 2 3 4 5 6 7

Strongly disagree Strongly agree

D6. I believe that my organization actively monitors the content of employees' e-mail messages. *

1 2 3 4 5 6 7

Strongly disagree Strongly agree

1812
1813

E. Computer User Intentions

Scenario 1: Taylor is a manager in a company where he was recently hired. His department uses inventory application software to make inventory purchases. To ensure that only authorized individuals make inventory purchases, the company has a firm policy that employees must log out or lock their computer workstation when not in use. However, to make work more convenient, Taylor's boss directs him to leave his user account logged-in for other employees to freely use. Taylor expects that keeping his user account logged-in could save his company time.

INT1a. If you were Taylor, what is the likelihood that you would have kept your user account logged-in in order to save your company time? *

1 2 3 4 5 6 7

Very unlikely Very likely

INT2a. I could see myself keeping my account logged-in to save my company time if I were in Taylor's situation. *

1 2 3 4 5 6 7

Strongly disagree Strongly agree

1814
1815

Scenario 2: Alexandra is a supervisor in a company where she was recently hired. Her company has a strong policy that each computer workstation must be password-protected and that passwords are not to be shared. However, Alexandra is working out in the field for the week and one of her co-workers needs a file on her computer. She expects that sharing her password could save her company a lot of time. Alexandra shares her password with her co-worker.

INT1b. If you were Alexandra, what is the likelihood that you would have shared your password with co-workers to save your company a lot of time? *

1 2 3 4 5 6 7

Very unlikely Very likely

INT2b. I could see myself sharing my password with co-workers to save my company a lot of time if I were in Alexandra's situation. *

1 2 3 4 5 6 7

Strongly disagree Strongly agree

1816
1817

Scenario 3: Jordan is given a personal computer (PC) at work. The new PC came with a label containing her username and password. Jordan believes it would make her more effective on the job by leaving the username and password as it is since she has too many passwords, while it is difficult to remember them all. Jordan leaves her username and password visible.

INT1c. If you were Jordan, what is the likelihood that you would have left your username and password visible? *

1 2 3 4 5 6 7

Very unlikely Very likely

INT2c. I could see myself leaving my username and password visible if I were in Jordan's situation. *

1 2 3 4 5 6 7

Strongly disagree Strongly agree

1818

Scenario 4: Chris is a manager in a company where he has worked for several years. Chris is currently working on a report that requires the analysis of the company's employee database. This database contains employees home addresses, names, phone numbers, and social security numbers. Chris will travel for several days and would like to analyze the database on the road. Chris expects that copying the data to his personal USB drive and taking it on the road could save the company a lot of time and money. Chris copies the corporate database to his portable USB drive and takes it with him for the travel.

INT1d. If you were Chris, what is the likelihood that you would have copied the data to your personal USB drive? *

1 2 3 4 5 6 7

Very unlikely Very likely

INT2d. I could see myself copying the data to my personal USB drive if I were in Chris's situation. *

1 2 3 4 5 6 7

Strongly disagree Strongly agree

APPENDIX B

Approval Letter to Collect Data from the Agency

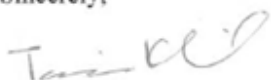

February 24, 2012

To Whom It May Concern:

Please be advised that Min Suk Choi has my permission to collect data from the computer end-users related to assessing the role of end-user computer self-efficacy, cybersecurity countermeasures awareness, and cybersecurity skills toward computer misuse intention at government agencies in furtherance of his doctoral studies at Nova Southeastern University.

Please, let me know if you have any questions.

Sincerely,

Tariq Habib
Chief Technology Officer

Re: *Assessing the Role of End-User Computer Self-Efficacy, Cybersecurity Countermeasures Awareness, and Cybersecurity Skills toward Computer Misuse Intention at Government Agencies*

IRB Approval Number: wang04151201

I have reviewed the above-referenced research protocol at the center level. Based on the information provided, I have determined that this study is exempt from further IRB review. You may proceed with your study as described to the IRB. As principal investigator, you must adhere to the following requirements:

- 1) **CONSENT:** If recruitment procedures include consent forms these must be obtained in such a manner that they are clearly understood by the subjects and the process affords subjects the opportunity to ask questions, obtain detailed answers from those directly involved in the research, and have sufficient time to consider their participation after they have been provided this information. The subjects must be given a copy of the signed consent document, and a copy must be placed in a secure file separate from de-identified participant information. Record of informed consent must be retained for a minimum of three years from the conclusion of the study.
- 2) **ADVERSE REACTIONS:** The principal investigator is required to notify the IRB chair and me (954-262-5369 and 954-262-2020 respectively) of any adverse reactions or unanticipated events that may develop as a result of this study. Reactions or events may include, but are not limited to, injury, depression as a result of participation in the study, life-threatening situation, death, or loss of confidentiality/anonymity of subject. Approval may be withdrawn if the problem is serious.
- 3) **AMENDMENTS:** Any changes in the study (e.g., procedures, number or types of subjects, consent forms, investigators, etc.) must be approved by the IRB prior to implementation. Please be advised that changes in a study may require further review depending on the nature of the change. Please contact me with any questions regarding amendments or changes to your study.

The NSU IRB is in compliance with the requirements for the protection of human subjects prescribed in Part 46 of Title 45 of the Code of Federal Regulations (45 CFR 46) revised June 18, 1991.
