Innovations in technologies for early detection of diseases like breast cancer, dementia, and atrial fibrillation are gaining increasing attention. The media is a key avenue through which tests are promoted to asymptomatic individuals, and could have an important role in encouraging realistic expectations of benefits and harms of early detection, including unnecessary diagnoses.¹ Evidence suggests medical media coverage tends to overplay benefits, downplay harms and ignore conflicts of interest,² but there are few data on coverage of early detection tests.

METHODS

We performed a cross-sectional study to examine global media coverage of benefits and harms of early detection tests for asymptomatic individuals. We also examined conflicts of interest among commentators in stories, as well as media disclosure of conflicts. We studied five early detection tests: 1. Blood-based liquid biopsy tests for cancer(s); 2. 3D mammography for breast cancer; 3. Apple Watch Series 4 electrocardiogram for atrial fibrillation; 4. Blood biomarker tests for dementia; and 5. Artificial intelligence technology for dementia. Our published protocol³ provides detail regarding selection of these tests.

We searched for all English-language stories from 2016 to 2019 in LexisNexis, ProQuest and Google News. We included all non-fictional story types from newspapers, blogs, magazines, broadcast and podcast transcripts, wire feeds/services, and webnews if they mentioned/implied a test benefit or harm. Pairs of independent reviewers screened stories for inclusion and coded stories for coverage of health benefits (e.g. early treatment, saves lives) and/or harms (e.g. false positives, overdiagnosis) and inclusion of commentator views with or without disclosure of conflicts of interest.

RESULTS

We included 1,173 stories: liquid biopsy (n = 124), 3D mammography (n = 579), Apple Watch (n = 273), blood biomarker tests (n = 128), artificial intelligence (n = 69).

Overall, 97% [95% CI 96-98%] reported on the benefits. (Figure 1) 37% (95% CI 34-40%) reported any harms, and only 34% (95% CI 31-36%) reported on both benefits and harms. 63% (95% CI 60-66%) of stories reported on benefits only, while only 3% (95% CI 2-4%) reported on harms only. There was variation between tests in the percentage reporting any harms (from 14% for artificial intelligence to 58% for Apple Watch and liquid biopsy) and both benefit and harm (from 14% for artificial intelligence to 54% for liquid biopsy). Harms were mentioned but deemphasized in just over one quarter (27%) of stories.

Overdiagnosis was only mentioned in 13% of stories that mentioned any harms – 5% of stories overall.

Overall, 39% of stories quantified a benefit. However, only 14% of these used absolute numbers. Overall 29% of stories quantified a harm. Almost half (46%) of these provided absolute numbers.

Over half (55% [95% CI 52-57%]) of all stories included the views of commentators with conflicts of interest, but these conflicts were only disclosed in 12% (95% CI 10-14%) of these stories. (Figure 2)

DISCUSSION

In this study, we examined how innovative early detection tests are covered in the media. The findings are important because of the potential of such tests to harm healthy people, in contrast to tests promoted for investigation of symptoms. Yet coverage emphasised benefits far more than harms, and the risk of overdiagnosis received little coverage. Our findings align with other medical media coverage studies.^{2,4,5} Coding benefits and harms involves subjective judgments, although we piloted an explicit coding scheme and had pairs of independent coders to minimise bias. We did not examine social media coverage. Higher quality reporting by journalists could encourage more healthy scepticism towards health options⁶ and curb overdiagnosis.¹ Strategies to improve media reporting so professionals, patients and public receive more balanced information about early detection tests are urgently needed.

Author contributions

Dr O’Keeffe had full access to all of the data in the study and takes responsibility for the integrity of the data and the accuracy of the data analysis.

Study conception: O’Keeffe
