**Table S1** - Periodic assessments of previously unrecorded tree mortality in the both the high density ( $\rho_H$ ) and low density ( $\rho_L$ ) plots and scaled up to a hectare (ha).

Year	No. trees (ha)	No. trees (plot)	Mortality (ha)	Mortality (ha)	Stand
1955	3805	400	30	12	$\rho_H$
1969	3241	341	154	16	$\rho_H$
1974	2823	297	413	43	$\rho_H$
1980	2471	260	351	37	$\rho_H$
1985	2148	226	323	34	$\rho_H$
1990	1929	203	218	23	$\rho_H$
1955	1258	152	27	11	$\rho_L$
1969	1240	150	16	2	$\rho_L$
1974	1215	147	24	3	$\rho_L$
1980	1157	140	53	6	$\rho_L$
1985	1074	130	82	10	$\rho_L$
1990	1008	122	66	8	$\rho_L$

**Table S2** – Results of the pairwise comparison of slopes between the three drought years. *Df* = degrees of freedom, SE = standard error.

<b>Drought year comparison</b>	<b>Estimate</b>	<b>SE</b>	<b><i>df</i></b>	<b>t.ratio</b>	<b>p.value</b>
1976 - 1984	-0.142	0.051	773	-2.809	0.014
1976 - 1995	0.148	0.050	773	2.951	0.009
1984 - 1995	0.290	0.050	773	5.763	<0.001

**Table S3** - Post-hoc analyses of estimated marginal means for BAI between the three drought events (1976, 1984 and 1995) in the drought year (Year 0) and four post-drought years (Years 1-4).

Significant values ( $p < 0.05$ ) are highlighted in bold.

**Table S4** - Post-hoc pairwise comparison of estimated marginal means for the proportion of trees growing at < 2 SD of the SPEI-constrained pre-drought growth averages (BAI1976<sub>con</sub>, BAI1984<sub>con</sub>, BAI1995<sub>con</sub>) for all three drought events (1976, 1984 and 1995). Pairwise comparisons were conducted annually between all three droughts for events (Year = 0) and in the four post-drought years (Year = 1, 2, 3 and 4). Significant results are highlighted in bold, and *p-values* were adjusted using a Bonferroni correction to adjust for multiple tests and SE = standard error.

**Supplementary Figure S1** - Individual tree and mean percentage growth change relative to  $RWI_{1976_{con}}$ ,  $RWI_{1984_{con}}$  or  $RWI_{1995_{con}}$  values for the 1976 (a, b), 1984 (c, d) and 1995 (e, f) droughts respectively, calculated annually for both high density ( $\rho_H$  – a, c, d) and low density ( $\rho_L$  – b, d, f) stands.  $RWI_{con}$  values represent the pre-drought growth averages calculated using the same approach as for BAI in the main text but from ring width data detrended using a cubic smoothing spline with a 30-year cut off. Grey lines are individual trees, while solid green lines and green shaded area are the annual mean  $\pm$  1SD across all trees at a given density. Solid horizontal dashed black lines indicate no detectable difference between a given years growth and  $RWI_{con}$  (growth rates have recovered to  $RWI_{con}$  levels for each drought). High density ( $\rho_H, n = 29$ ) and low density ( $\rho_L, n = 27$ ).

**Supplementary Figure S2** – Change point analysis showing the years where abrupt changes (e.g. thresholds - vertical black dashed lines) in growth dominance ( $G_d$ ) (grey lines) were detected for (a) the high ( $\rho_H$  – 1973, 1983 and 1990) and (b) low ( $\rho_L$  – 1970 and 1985) density treatments along with the corresponding 95% confidence intervals (red error bars). Horizontal yellow lines indicate the null model (linear regression line with no change points) and blue lines represent fitted regression lines of linear models with break points. Note the year indicated by each change point is the last year of the previous period (i.e., 1 year before a change to a lower or higher  $G_d$  level, so a change point in 1983 would indicate a change occurred in 1984).
