

Contribution to the Odonata fauna of Albania and Montenegro

DÁVID MURÁNYI & TIBOR KOVÁCS

ABSTRACT: Faunistical data of 37 Odonata species collected in Albania since 2007, and 20 species collected in Montenegro during the past ten years are enumerated. *Selysiothemis nigra* (Vander Linden, 1825) is new to the fauna of Albania. Notes and figures are given concerning the taxonomy, distribution, and ecology of 15 taxa.

Introduction

Until the past ten years, the Odonata fauna of Albania and Montenegro was rather poorly studied. The previous research in Albania was discussed and contributed by MURÁNYI (2007), since then date were added regarding faunistics and taxonomy (KITANOVA et al. 2013, MURÁNYI 2010, OLIAS et al. 2007), and some ecofaunistical aspects (e.g. HALIMI et al. 2010). Very recently, another comprehensive overview and contribution was published on the Odonata fauna of Montenegro (DE KNIJF et al. 2013).

In this paper we publish the Odonata material gathered as side targets by researchers and collaborators of the Hungarian Natural History Museum, the Mátra Museum of the Hungarian Natural History Museum, and the Hungarian Academy of Sciences during the last ten years in Montenegro, and in Albania since 2007. Besides the enumeration of faunistical data, we give notes and figures for taxonomy, distribution, and ecology of the some species found.

Material and methods

Specimens were collected by singling, with waternet, or sweeping net. They are stored in 70% ethanol and deposited in the Collection of Lesser Insect Orders, Department of Zoology, Hungarian Natural History Museum (HNHM), and in the Invertebrate Collection of the Mátra Museum of the Hungarian Natural History Museum (MM).

Nomenclature and works used for identification are as in MURÁNYI (2007). The localities are shown on a map of the Central-West Balkans (Fig. 1).

Females caught and observed at Omarë spring lake are androchrome, while all females at the Drin River were normal coloured. At Qukës Shkumbin we observed both forms. The small sized male from the Kir River seems to be intermediate towards *C. splendens splendens*, having less extended blue on the wings. Subspecific identity of the exuviae found at the Cijevna River are questionable.

Subspecific identity of larvae and exuviae can be presumed on the basis of the range of *C. virgo festiva*, covering all the territory of Albania and Montenegro.

LESTIDAE Calvert, 1901

Lestes dryas Kirby, 1890 – **Albania**, Bulqizë district, Çermenikë Mts, Ballenjë, marshy puddle beneath the settlement, N41°22.570', E20°15.516', 1395 m, 21.06.2012, FZ-KT-MD, 2 ♂, 2 ♀ (HNHM: 2012/57) – Korçë district, Vallamarë Mts, alpine lake on the N slope of a mountain S of Mt. The female from the Vallamarë Mts was reported as the first occurrence of *L. dryas* in Albania (MURÁNYI 2010). However, details were not included in the abstract of that presentation, so we report it herein again, together with a further new locality.

Lestes parvidens Artobolevskii, 1929 – **Albania**, Shkodër district, Prokletije Mts, Theth, Shalë River beneath the village, N42°23.138', E19°46.845', 715 m, 09.10.2012, JP-KT-MD-PG, 1 ♀ (HNHM: 2012/18).

As larvae of these two species are not sufficiently known, we cannot identify our larvae to species. However, data can be informative to a further check for the imagos.

Subspecific identity of larvae can be presumed on the basis of the range of *P. pennipes nitidula*; the nominotypical subspecies is known only from the NE of Montenegro in the area studied. Short black markings on tibiae, characteristic for *P. pennipes nitidula*, conspicuous on all of our imagos (Figs 2–3).

As already reported by DUMONT et al. (1993) and MURÁNYI (2007), the southern Albanian specimens have more extensive yellow markings (Figs 6–7) than the usual form (Figs 8–9). Unfortunately, our specimens were not suitable for the recent molecular studies (FROUFE et al. 2013). It is worth to mention that a last-year larva caught in October 2008 above Stari Bar, Montenegro, was found beneath a large stone some 10 meters above the stream. The gorge is covered with dry macchia vegetation, and the larva possibly lived in a temporary seep that was drought since months. This peculiar case contradicts the suggestion of DEKNJIF et al. (2013) that *Cordulegaster* larvae can live only in permanent waterflows.
