WORLD FERTILITY SURVEY

**THE
KOREAN
NATIONAL
FERTILITY
SURVEY**

1974

FIRST COUNTRY REPORT

**NATIONAL BUREAU OF STATISTICS
OF THE ECONOMIC PLANNING BOARD
KOREAN INSTITUTE FOR FAMILY PLANNING**

PREFACE

This report is a result of the 1974 Korean National Fertility Survey which was jointly undertaken by the National Bureau of Statistics of the Economic Planning Board and the Korean Institute for Family Planning with a close collaboration of the WFS London Office and the International Statistical Institute. Although fertility and other demographic surveys have been undertaken in Korea since 1964, this study is considerably more detailed and comprehensive than any other previous surveys. It provides data which will permit a thorough assessment of fertility trends, and which will enable us to have deeper insights into the myriad patterns of fertility and family planning behavior.

I hope that these data will not only make a material contribution to the improvement of national welfare of Korea by providing better information for social and economic planning, but also will be of interest and use to other countries.

This first report covers only basic findings and tables. Plans are underway for an indepth analysis of certain portions of the large amount of data. A series of monographs reporting further findings will be issued over the next few years.

The successful implementation of this project would not have been possible without the active and dedicated efforts of a large number of persons. I wish to acknowledge in particular the support and technical assistance from WFS London and from Professor Yuzuru Takeshita, the Country Co-ordinator. I wish also to thank Messrs. John Cheland, Vijay Verma and M. Pasaba, and Miss Marie Argana for their valuable contributions. Special thanks are due to the Korean Institute for Family Planning and its Research Director, Mr. Ehn Hyun Choe, and his staff. Mr. Choe and his staff carried a major responsibility for the field operation of the survey and the preparation of final report.

I wish also to acknowledge the cooperation and assistance rendered by Dr. Richard Moore, the UNFPA Coordinator in Korea.

Seung Kun Park
Director General
National Bureau of Statistics
Economic Planning Board

Seoul, Korea

PREFACE	
CHAPTER 1. THE BACKGROUND OF THE STUDY	17
1.1 STATEMENT OF THE MAIN OBJECTIVE	17
1.2 COUNTRY BACKGROUND	19
1.3 EXECUTING AGENCIES, FUNDINGS, STEERING AND TECHNICAL ADVISORY COMMITTEES (AND CONSULTANTS)	23
1.4 TIME SCHEDULE OF THE PROJECT: PROJECTED AND ACTUAL	26
CHAPTER 2. METHODOLOGY OF THE STUDY	27
2.1 THE QUESTIONNAIRES	27
2.1.1 The Household Schedule	27
2.1.2 The Individual Questionnaire	28
2.1.3 The Community Questionnaire	30
2.2 PRE-TEST, INSTRUCTION MANUAL AND TRANSLATION	30
2.2.1 Pre-tests	30
2.2.2 Instruction Manuals	32
2.2.3 Translation	32
2.3 SAMPLE	32
2.3.1 Sample Size	32
2.3.2 The Sample Design	33
2.3.3 Sampling Frame	33
2.3.4 Sampling Fraction of Households	33
2.3.5 First Stage: Sampling of ED's	34
2.3.6 Mapping and Listing	35
2.3.7 Second Stage: Selection of Households	35

	Page
2.3.8 Third Stage: Selection of Individuals	36
2.3.9 Details of Sampling Implementation.....	36
2.3.10 The Results of Sampling Implementation	37
2.4 THE ORGANIZATION AND EXECUTION OF THE FIELD WORK	38
2.4.1 Recruitment of the Field Personnel	38
2.4.2 Training of Field Personnel.....	39
2.4.3 Field Work and Supervision.....	40
2.4.4 Case Load and Length of Interviews	43
2.5 MANUAL EDITING, CODING AND KEY-PUNCHING.....	44
2.5.1 Preparation of Codes	44
2.5.2 Manual Editing and Coding.....	44
2.6 PREPARATION OF CLEAN TAPES, RECODING AND TABULATION.....	45
 CHAPTER 3. COMMENTARY ON THE MAIN FINDINGS	 46
3.1 GENERAL INTRODUCTION	46
3.2 POPULATION ENUMERATED IN THE HOUSEHOLD SCHEDULE	47
3.2.1 Introduction.....	47
3.2.2 Overall Population Composition	47
3.2.3 Population Distribution by Size of Community	51
3.2.4 Age-Sex Composition by Size of Community	53
3.2.5 Population Distribution by Marital Status.....	53
3.2.6 Population Distribution by Educational Attainment.....	54
3.2.7 Summary	55
3.3 BACKGROUND CHARACTERISTICS OF INDIVIDUAL SURVEY RESPONDENTS.....	56
3.3.1 Introduction	56
3.3.2 Age and Marital Duration.....	56
3.3.3 Education and Literacy.....	57

	Page
3.3.4 Type of Place of Residence.....	60
3.3.5 Religion	60
3.3.6 Husband's Occupation	60
3.3.7 Pattern of Work	61
3.3.8 Number of Modern Objects.....	63
3.3.9 Summary	63
3.4 NUPTIALITY AND EXPOSURE TO CHILDBEARING	65
3.4.1 Introduction	65
3.4.2 Trends in Proportion Single by Age Group.....	65
3.4.3 Trends in Age at First Marriage	66
3.4.4 Differentials in Age at First Marriage	67
3.4.5 Marital Stability	70
3.4.6 Exposure Status	73
3.4.7 Summary.....	73
3.5 FERTILITY	76
3.5.1 Introduction	76
3.5.2 Cumulative Fertility by Birth or Marriage Cohort.....	76
3.5.3 Differentials in Cumulative Fertility	80
3.5.4 Fertility in the First Years of Marriage	86
3.5.5 Current Fertility	88
3.5.6 Mean Number of Live Births in the Past Five Years and Proportion Currently Pregnant.....	94
3.5.7 Summary.....	95
3.6 SURVIVORSHIP OF CHILDREN	98
3.6.1 Introduction	98
3.6.2 Infant Mortality	98
3.6.3 The Effects of Mortality on Family Size	99
3.6.4 Summary	100

CHAPTER 1

THE BACKGROUND OF THE STUDY

1.1 STATEMENT OF THE MAIN OBJECTIVES

The 1974 Korean National Fertility Survey (KNFS) was undertaken as part of the World Fertility Survey (WFS), an international programme of research into human fertility. The WFS was launched in 1972 in response to the announcement of World Population Year 1974 and the United Nations' call for concerned, world action on population matters. It is a project of the International Statistical Institute (ISI) undertaken with the collaboration of the United Nations and in cooperation with the International Union for the Scientific Study of Population (IUSSP).

1.1 WFS OBJECTIVES

The basic aim of the WFS is to assist as many countries as possible to acquire the scientific information that will permit them to describe and interpret their fertility levels and patterns, and to facilitate national efforts in economic, social, and health planning. By providing such assistance, the WFS aims further to increase national capacities and eventually global capacity by enrolling as many as 40 to 50 countries world-wide for fertility and other demographic research by the provision of a cadre of trained personnel. More immediately, the WFS aims to collect and analyze data on fertility which are internationally comparable, therefore permitting comparisons across countries and regions, and promote world understanding of its fertility and population situation. An important subsidiary aim, a by-product in effect, is the provision of a body of methodological and substantive literature on fertility studies, thus contributing to the cumulative, scientific knowledge about human fertility.¹⁾

1.1.2 KNFS OBJECTIVES

These aims of the WFS were seen as eminently consistent with the needs in Korea, when an invitation to participate was received from the ISI in early 1973. Korea accepted quickly and embarked upon a survey in 1974, thus becoming one of the very first countries to mount a survey under the WFS programme.²⁾

The Government of the Republic of Korea has very specific demographic targets built into its economic development plans: an annual population growth rate of 1.7 per cent by 1976 and 1.6 per cent by 1981. The national family planning programme, underway since 1961, has been carefully articulated with these targets. A periodic assessment of the demographic situation and the impact of the organized family planning programme is a necessary exercise. In Korea, however, this effort is handicapped in no small measure by the absence of a reliable vital

1) A fuller statement, from which this paragraph is adapted, is found in the WFS document, *Survey Organization Manual*, WFS/TECH. 134, January 1975, pp. 2-3.

2) One compelling reason for mounting the survey so soon in 1974 was to avoid an overlap with the quinquennial population census that is scheduled for October, 1975.

statistics registration system. She has had to rely on sample surveys and other indirect means to estimate her vital rates. The WFS programme was seen as a timely opportunity to obtain these estimates-fertility, in particular and other related data to provide another measure in a series of periodic assessments conducted, over the years. The findings were expected to contribute to the Government's development planning efforts generally and to its evaluation of the national family programme in particular.

The WFS programme, with its emphasis on obtaining data of the highest quality, was seen also as an opportunity to improve Korea's fertility estimates and enhance further her capacity for fertility and demographic research. The last decade had seen marked improvements in both these respects. The present exercise was seen to fit in well with Korea's continued striving for excellence in this sphere.

Finally, for a long time concerned with the national population problem, the Government of the Republic of Korea had earlier endorsed the United Nations' call for concerted, world action on population matters³⁾ and saw participation in the WFS programme as an appropriate way to commemorate the World Population Year 1974. The survey was announced and promoted throughout the country as an activity of the World Population Year. This is illustrated in the prize winning poster commemorating that year, reproduced here as Figure 1. This poster was distributed throughout the country to announce the 1974 Korean National Fertility Survey.

Figure 1. KOREAN NATIONAL FERTILITY SURVEY POSTER

3) President Chung Hee Park was one of the signatories of the UN call publicized in 1973.

1.2 COUNTRY BACKGROUND

1.2.1 GEOGRAPHY AND LOCATION

The Republic of Korea, traditionally known as the Land of the Morning Calm, occupies the Korean peninsula, a mountainous arm of land which extends roughly 1,000 km. in length and is 216km. wide at its narrowest point. The peninsula is separated from China and the Soviet Union to the north by the natural boundary of the Yalu and Tuman Rivers. To the east, the Japanese archipelago lies across the East Sea on the west, the Yellow Sea separates Korea from the Chinese mainland. (See Figure 2.)

The coastline is much indented, with several major ports in Korea; Incheon, Pusan, Masan and Mogpo. There are several thousand offshore islands, though relatively few are of habitable size.

Korea is a mountainous land, with numerous ranges of steep, rock-faced peaks covering about 70 per cent of the total land area. Rivers are mostly short and swift; notable exceptions are the Nakdong, Kum, and the 500km. long Han, which flows through the capital city of Seoul on its course to the Yellow Sea. Korea has a temperate climate with a rainy summer season when as much as half of the annual rainfall occurs.

The land area of the Republic of Korea is slightly under 100,000 sq.km., about the size of Austria or Portugal. Its population, according to the most recent Census (1975), numbered 34.7 million, with a resulting density of 351 persons per sq. km., among the highest in the world.

Administratively, the Republic of Korea is divided into nine provinces and two special cities. In addition to its role as the national capital, Seoul is by far the largest city, with a 1975 population of 6.9 million. Seoul is the financial, cultural, and educational centre of the nation, and is the home of one out of five Koreans. The other special city, Pusan is the nation's second largest (1975) population of 2.5 million), and the major port along Korea's southern coast. Currently, 48 per cent of the national population lives in cities of over 50,000 population.

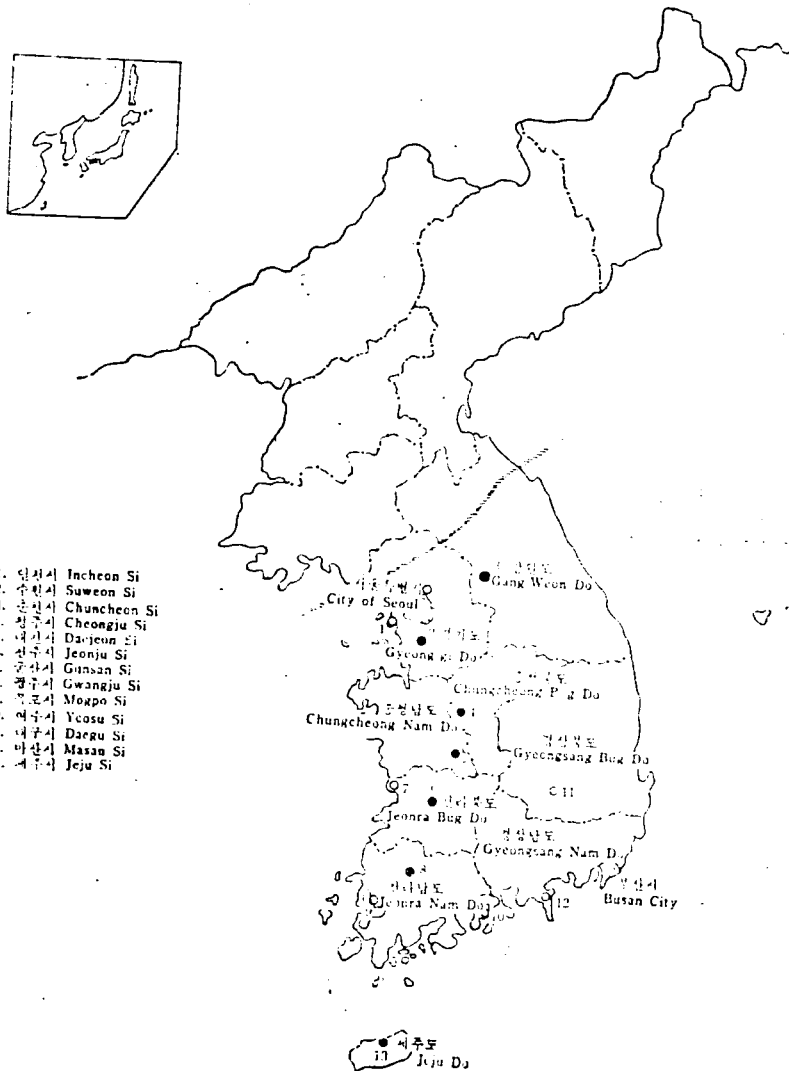

1.2.2 SOCIAL AND ETHNIC BACKGROUND

The Korean population is essentially a single homogeneous ethnic group, distinct from its Chinese and Japanese neighbours. The original settlers of Korea are thought to have been various Mongol tribes who migrated southward from what is now Manchuria onto the peninsula in prehistoric times.

As part of their common cultural heritage, present day Koreans share a single written and spoken language, and literacy is quite high. The combination of these two factors greatly enhances internal communications in Korea, and facilitates the successful implementation of such surveys as the present one.

The basic ideology of Korean society has been, for many hundreds of years, a form of neo-Confucianism. This ideology has fostered the evolution and persistence of several traditional characteristics of marriage and family life, including the near-universality of marriage monogamy extended family structure, and strong social pressure for having sons. Until relatively

Figure 2. MAP OF THE REPUBLIC OF KOREA

recently, the strong family and regional ties deriving from Confucian teachings acted against the emergence on the Korean peninsula of a modern nation. Ruled by a series of dynasties until Japanese annexation in 1910, Korea was not "opened" to the West until the latter part of the 19th century.

The life of a Korean is marked by a number of significant milestones, formal "rites of passage," which are duly celebrated and recorded by his family. The two most important, *dol* and *hwangap*, respectively mark the first and sixtieth anniversaries of an individual's birth. The latter further denotes the completion of five 12-year animal cycles, a landmark of life (and until recently a rarely-achieved one) calling for family celebration. One result of the importance of these and other age-graded observances is the highly accurate record keeping by parents of the birth dates of their children. Misreporting of age is rare in Korea; the validity of age data in censuses and surveys may be assumed to be uniformly high.

1.2.3 ECONOMY

Any discussion of the recent economic history of Korea must include reference to the wrenching effects of foreign intervention on national development. Liberated in 1945, from a 36-year period of Japanese occupation, Korea soon afterwards became the battleground of a destructive three-year war which ended in 1953 in an uneasy armistice and political division roughly following the 38th parallel.

Traditionally an agrarian society, the recent economic growth of Korea has transformed the country into an industrial and rapidly urbanizing nation, with all the associated advantages -and disadvantages- of a such rapid development. Since the early 1960's, the Gross National Product has grown at an average annual rate of about ten per cent; per capita income has increased six-fold in the past fifteen years. Agriculture has been modernized; the limited energy and mineral resources are being exploited, and exports continue to increase. Such progress, however, creates new problems of its own. Cities are growing faster than their capacities to absorb additional population, resulting in housing shortages, congestion, and rising unemployment. Rapid industrial development has raised the standard of living and contributed greatly to the balance of trade, but it has also created serious problems of air and water pollution in some of the nation's most densely populated areas.

Transportation and communication facilities, a pre-requisite to economic development, are well developed. In 1970, a fourline highway was completed between Seoul and Pusan; numerous tributary routes to this main north-south link have brought all parts of the country into much closer accessibility.

Guiding the course of recent economic development has been the series of Five-Year Plans, initiated in 1962, with the goal of sustained and balanced growth in all sectors of the economy. The targets of the fourth plan, beginning in 1977, are the establishment of a base for a self-sufficient economy, the promotion of social development, and increased efficiency and technological innovation.

Also an integral part of the nation's developmental effort is the Saemaul (New village) Movement a campaign to raise the living conditions of the Korean people, particularly in rural areas, begun in 1971. The theory behind the movement is that a "self-supporting" community will be able to break the cycle of backwardness and poverty that has marked most of rural Korea for centuries, and lead to increased individual productivity and income, with a consequent higher living standard.

1.2.4 EDUCATION

As already noted, literacy in Korea is quite high generally and nearly universal in the younger ages. Education through the primary level (six years) is compulsory, and the government plans to extend this through junior high school by 1981. Vocational training has been emphasized at the university level, and the student population is rapidly increasing, proportionately as well as in absolute numbers. Noteworthy in the past decade is the growing number of young women in secondary and higher education, reflecting the rising status of women.

1.2.5 POPULATION GROWTH AND FAMILY PLANNING

In 1960, the population was about 25 million and was growing at the rate of three per cent a year. The total fertility rate was about six children per woman and life expectancy at birth, 57 years. Fifteen years later, the population had increased by forty per cent to 35 million, but the annual rate of increase had been cut to 1.7 per cent. The total fertility rate had declined to 3.5 children by 1975, and life expectancy had risen to 68 years.

Much of this improvement in Korea's demographic outlook may be attributed to the national family planning programme, initiated in 1962 as part of a newly formulated national population policy. The First Five-Year Economic Development Plan, introduced in 1962, included a declaration that "a measure to control population will be needed" due to the increasing growth rate resulting from rapidly improving health conditions in the decade following the Korean War. The goals of this policy were to reduce annual rates of growth to 2.5 per cent in 1966 and further to 2.0 per cent by 1971; explicit annual contraceptive targets were set towards the realization of these goals.

These declines in the growth rate were reached partly by the achievement of target levels of acceptors, but also as a result of socio-economic changes. Age at marriage rose rapidly during the 1960's and induced abortion became more widespread. Health programmes improved and reached greater proportions of the population. Urbanization and rapid economic growth of the 1960's and early 1970's contributed to the decline in the natural increase rate.

The Ministry of Health and Social Affairs is the implementing agency of the national family planning programme. In 1970, the National Family Planning Centre, now the Korean Institute for Family Planning, or KIFP, was established to support the national programme in the areas of training, evaluation, and research. Specifically, it provides training for family planning workers, maintains ongoing records of program acceptance and continuation, and undertakes the series of national surveys in fertility and family planning.

The Planned Parenthood Federation of Korea (PPFK), a voluntary organization affiliated with the International Planned Parenthood Federation, was founded in 1961. PPFK maintains offices in each of the nine provinces as well as a central staff in Seoul and, through its intermediary role between the government and the public, provides much of the information, education and communication (IE&C) activities that support the family planning programme in Korea.

1.3 EXECUTING AGENCIES, FUNDINGS, STEERING AND TECHNICAL ADVISORY COMMITTEES AND CONSULTANTS

1.3.1 EXECUTING AGENCIES

The 1974 Korean National Fertility Survey was undertaken jointly by the Bureau of Statistics (BOS) of the Economic Planning Board (EPB) and the Korean Institute for Family Planning (KIFP), supported by the Ministry of Health and Social Affairs. The involvement of these particular agencies reflects the Government's interest in undertaking this survey for the purpose of obtaining data of relevance to economic planning and the national family planning programme.

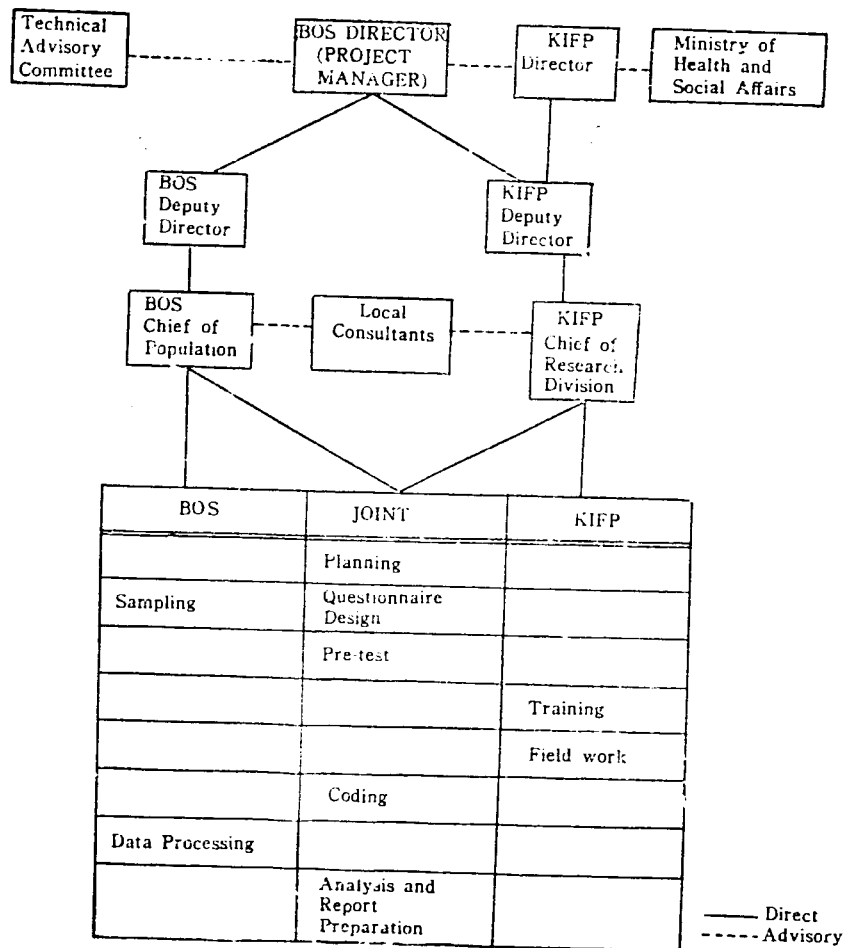

The Economic Planning Board is the chief planning unit of the Government. The Bureau of Statistics, placed under this body, is responsible for collecting a wide range of statistics for the Government, including population and vital statistics. Since the Korean War, it has mounted five national censuses (1955, 1960, 1966, 1970 and 1975). It is also experienced in survey work, as it is frequently commissioned to take special purpose surveys ranging from unemployment to vital statistics.⁴ It has facilities for, among other things, sampling, field work, coding and data processing.

The Korean Institute for Family Planning, unlike the Bureau of Statistics, is a semi-autonomous agency, formally established in 1971 as an adjunct to the national family planning programme, which is supervised by the Ministry of Health and Social Affairs. It originated in 1965 from a small Evaluation Unit in the Family Planning Section of the Ministry of Health and Social Affairs, became a Centre in 1970, and finally an Institute in 1971. It now has a professional staff of about 50 and is engaged in the training of family planning workers; family planning and population education of community leaders, students and other groups; the evaluation of the national family planning programme; and research in population and programme related areas. Its experience in fertility surveys is impressive, having mounted prior to 1974 full-scale national surveys in 1968, 1971 and 1973⁵.

These two agencies, with staff and facilities that complement each other, joined forces for the first time on a formal basis to carry out the 1974 Korean National Fertility Survey under the WFS programme. The Director of the Bureau of Statistics served as the overall Project Manager with support from the Director of the Korean Institute for Family Planning. Both were assisted by their respective Deputy Directors in overseeing the administrative and financial aspects of the project. The day-to-day activities, both administrative and technical, were supervised by the Chief of the Population Division at the BOS and the Chief of the Research Division at the KIFP. The latter served as the Field Director during the field period (September-December, 1974) in as much as the KIFP, by pre-arrangement, was charged with organizing and overseeing all field activities. Listed in Appendix 12 are the individuals who served in these and other capacities.

4) For example, a Special Labour Force Survey was taken in 1974, a Special Demographic Survey in 1966, and series of quarterly vital statistics surveys since 1963.
5) See the following reports from these surveys:
The Korean 1968 Fertility and Family Planning Survey, Seoul: National Family Planning Center, 1970
Report on 1971 Fertility-Abortion Survey, Seoul: Korean Institute for Family Planning, 1973
1973 National Family Planning and Fertility Survey: A Comprehensive Report, Seoul: Korean Institute for Family Planning, 1974

FIGURE 3. CHAIN OF COMMAND AND DIVISION OF LABOUR : 1974 KNFS

The overall responsibility for the project was shared by the two agencies from beginning to end, but responsibilities for some specific tasks were divided according to the special facilities available at each agency. Figure 3 shows diagrammatically the chain of command and division of labour for this survey.

Project headquarters was at the BOS, except for the five-months period (August-December, 1974) when the KIFP served as headquarters for training and field work.

1.3.2 STEERING AND TECHNICAL ADVISORY COMMITTEE

A Steering Committee was set up soon after Korea accepted the ISI invitation to participate in the WFS programme and provided the initial impetus in planning for the local project. Its membership represented the three agencies sponsoring the project.

Both the Economic Planning Board and the Ministry of Health and Social Affairs, by serving as sponsoring agencies, provided the legitimacy for this project in the public's eyes and facilitated its successful implementation at all levels.

Early in the project, the Project Manager, in his capacity as the Director of the Bureau of Statistics, requested the subcommittee for Population and Social Statistics of the Statistical Council, an advisory body to the Bureau of Statistics, to serve as the Technical Advisory Committee for the 1974 Korean National Fertility Survey. Its membership represented the whole spectrum of local expertise whose collective counsel was indispensable for an undertaking of such national significance as the present survey. The committee reviewed the study design—the survey instruments in particular—and provided overall guidance to the project at several critical stages.

In addition to the counsel of the Technical Advisory Committee, the project called on several individual consultants from the local universities for advice and guidance on specific technical matters.

1.3.3 FUNDING AGENCY

The funding for the project was secured, with the assistance of the ISI, from the United Nations Funds for Population Activities (UNFPA), which granted a sum covering 60 per cent of the total budget of the project, outside of the regular UNFPA country allocation and prior to its approval of a grant for the WFS to ISI. The grant was administered in Korea by the UNFPA Country Co-ordinator under the supervision of the UNDP Resident Representative's office. The local project manager was accountable to UNDP/Korea on a monthly basis through a financial report and on a quarterly basis through both a financial and a technical progress report, copied to the ISI in the Hague.

Government contribution to the project amounted to about 40 per cent of the total budget including, among other items, the salaries of the senior staff and all computer costs. UNDP/Korea assisted in buying abroad two tax free station wagons and five cassette tape recorders, and also permitted on several occasions substantial increases on particular budget items and/or shifts among them when unanticipated expenditures had to be made.

1.4 TIME SCHEDULE OF THE PROJECT: PROJECTED AND ACTUAL

As a guide to planning, the project activities were identified in detail and time schedule projected. In the course of implementation several adjustments had to be made. Presented below are the major survey activities with both the projected and the actual time schedule:

ACTIVITY	TIME SCHEDULE	
	PROJECTED	ACTUAL
1. Project Preparation	Jan 1974	Approved in May 1974
2. Sampling	Jan. -July 1974	Feb. -Aug. 1974
3. Questionnaire Design and Pre-test	May. -June 1974	Apr. -Aug. 1974
4. Training and Field Operation	Jul. -Nov. 1974	Aug. -Dec. 1974
5. Tabulation Plan	July 1974	April 1975
6. Data Processing	Oct. -Dec. 1974	Jan. 1975-Dec. 1976
a) Coding	—	Jan. -May 1975
b) Field reconciliation	—	May-Jun 1975
c) Machine editing	—	Jul. -Nov. 1975
d) Additional age corrections of household data	—	Dec. 1975-Feb. 1976
e) Variable recode	—	Jan. 1976
f) Sample coverage check	—	May. -June 1976
g) Sample adjustment	—	Jul. -Aug. 1976
h) Tabulation of tables	—	Sep. 1976-May. 1977
7. Preparation of Country Report	Apr.-Aug. 1975	Aug. 1977-Nov. 1977

CHAPTER 2

METHODOLOGY OF THE STUDY

2.1 THE QUESTIONNAIRES

Three questionnaires were used in the 1974 Korean National Fertility Survey: the household schedule, the individual questionnaire, and the community questionnaire. Each of these instruments was modelled after the respective WFS versions that were available as of August 1974. To meet the specific local needs and interests, however, each instrument was expanded, without sacrificing basic comparability with all other efforts under the WFS programme either by incorporating the WFS modules that were available by then or by adding new questions pertinent to the Korean situation.

2.1.1 THE HOUSEHOLD SCHEDULE (SEE APPENDIX 1)

The household schedule in Korea was used not only as a screening device to identify the sample for the individual survey but also as an important source of data in its own right. It was to be administered in a sample of households large enough to provide an adequate basis for obtaining at least national if not also regional estimates of fertility and mortality—sorely lacking in Korea, as was noted earlier, from routine sources.

The WFS model includes the following items: a list of all household member, by relationship to head of household, age, sex, education, and marital status of each member; and for each ever-married woman, the total number of children living and deceased by sex, the date of birth of the most recent child, its sex, and its survivorship.

In addition to these questions on household membership and fertility, the Korean version included questions on mortality, adapted from the WFS General Mortality Module, and several questions on household characteristics to permit analysis of differential fertility and mortality. The added mortality questions are of two types: (1) the Brass-type questions (columns 9-14) on the survivorship of the parents of each person listed as a *de jure* (i.e., usual residence) or *de facto* (i.e., slept there "last night") member of the household; and (2) a question (No. 35) on any deaths in the household during the past two years. The objective was to obtain reliable estimates of deaths within the last 12 months without having to worry about boundary problems associated with such questions when asked in terms of a time reference of exactly one year. The 12-months estimate could be obtained from the date of death asked of each such event.

The added questions on household characteristics included: number and type of modern objects owned (No. 36), type of living quarters and ownership status (No. 37-38), size of living quarters (No. 39-40), and farm status and size (No. 41-45). These, in addition to the educational status... of each household member (from the WFS model) and the location of the sample households (urban, town, or rural—for example), could be used to analyze differential fertility and mortality.

The Korean household schedule varies from the WFS model in one other significant way. In asking for the date of birth and age of each household member (columns 6, 7 and 8) and the

date of death, if appropriate, of the most recent live birth (column 27), certain cultural factors associated with the reporting of dates in Korea are taken into account:

1. In the first place, dates tend to be reported interchangeably in either the solar (or Western) calendar or the lunar (or Korean) calendar. By referring to an almanac, or a conversion table adapted from it, dates are mutually convertible from one calendar to another once the calendar used in reporting the dates has been identified. Hence, in columns 6 and 27, the supplementary question: Is that solar or lunar calendar? follows the earlier question that asks for the date of the event.
2. In the second place, age tends to be reported according to a system where-by a person is one year old at birth and gains a year on the first of each subsequent year, thus complicating the calculation of the year of one's birth from the reported age. A person's Korean age, as age reported by this system is called, would differ from his or her exact age (i.e., age as of last birthday) by one to as much as two years. Thus, the question on age in column 7 must be followed in Korea by an additional question in column 8.
3. The third cultural practice is one quite common in this part of Asia long under the influence of pre-modern Chinese civilization: Korea, Japan, a number of countries bordering China in Southeast Asia, and of course China proper. The practice involves the use of a 12-animal cycle to identify any given calendar year—especially in identifying the year of birth. The full cycle actually contains 60 years, as the 12 animals (Rat, Ox, Tiger, Hare, Dragon, Snake, Horse, Ram, Monkey, Cock, Dog, and Boar) are combined with 5 elements (Wood, Fire, Earth, Metal and Water), alternating between positive and negative, but the usual practice is to refer to the year of birth (and age) by just the animal year of birth. Thus, by asking for a person's Korean age and the animal year of birth, the calendar year of birth can be determined accurately.

2.1.2 THE INDIVIDUAL QUESTIONNAIRE (SEE APPENDIX 2)

The individual questionnaire, which was administered to all ever-married women under 50 in a sub-sample of households subject to the household survey, is basically an extended version of the WFS Core (Mark I) available as of August 1974. The Korean questionnaire, therefore, is comparable with other surveys in the WFS programme where the Mark I Core has been used as a minimum, except for minor variations due to the revision of the model itself in London after August 1974. The major components of the questionnaire are indicated by the section headings:

- Section 1: Respondent's Background
- Section 2: Maternity History
- Section 3: Marriage History
- Section 4: Contraceptive Knowledge and Use
- Section 5: Fertility Planning
- Section 6: Family Size Values
- Section 7: Work History and Opportunity
- Section 8: Current (Last) Husband's Background

The Korean questionnaire extends the Core in several respects:

- 1) It incorporates some of the features of the WFS Core (Mark II) for low fertility countries such as, the integrated full pregnancy history (Section 2), the interval-by-interval full

contraceptive history (Section 5), and the more detailed probing with regard to the "wantedness" of the more recent pregnancies and future expectations (Section 5). These features were by and large present in past fertility surveys in Korea.

- 2) The Korean questionnaire includes selected items from three of the WFS-recommended modules: the Family Planning Module, the Abortion Module, and the Economic Module.

The emphasis of the family planning questions (Q 422-468) was on ascertaining the relative accessibility of service outlets and availability of follow-up services, on the premise that these factors contribute to both acceptance and continuation of contraception. Questions on the actual length of use of contraception were not included, however.

The inclusion of questions adapted from the Abortion Module was appropriate for Korea as abortion is a widely practiced form of birth control and is known to play an important role in limiting the Korean women's achieved fertility. In the pregnancy history chart, question 243 is intended to ascertain, for each non-fertile pregnancy, whether or not it was terminated by induced abortion. Further, for each pregnancy interval, there is a probe (Q245) as to whether there was another abortion.

Additional sets of questions concern knowledge and accessibility of places where abortion can be obtained (Q469-471); attitude towards induced abortion (Q472-473); and the likelihood of the respondent ever resorting to it in the future (Q474-475). The attitude scale recommended in the Abortion Module was not adopted in order to keep the length of the questionnaire manageable. Priority was given to seeking good estimates of the incidence of abortion over an attempt to ascertain the attitudinal dimensions of this practice, which is known to be widespread.

Questions dealing with the wife's work opportunity (Q722-731), the parent's aspiration for children's education (Q732-734), and the parent's expectation with regard to children's traditional role in the family (Q735-742) were adapted from the WFS Economic Module. Korean society is in a state of flux today, with changes taking place in the role of women and children in the family. These questions supplement the questions about the wife's work experience, included in the WFS Core, and were expected to yield data significantly related to fertility behaviour.

- 3) The third respect in which the questionnaire varies from the WFS Core is the inclusion of several questions that were dictated by the special interests and circumstances peculiar to Korea's fertility situation, not covered by the Core or any of the modules. For example, Section 6 includes the so-called Coombs' scales for family size and sex preferences. These and other additions are discussed in detail in Appendix 3.

In addition to supplementation in content, the Korean questionnaire includes a few variations from the Core that are more pragmatic than substantial:

- a. An unusual approach was adopted for recording the pregnancy history. This is presented in Appendix 4.
- b. As indicated for the household schedule, special questions were required to obtain dates of events.
- c. Other minor variations in the structure of questions which are too minor to discuss.

A more detailed account of deviations from the Core Questionnaire may be found in Appendix 3,

2.1.3 THE COMMUNITY QUESTIONNAIRE

The community questionnaire, adapted from the WFS model, was administered by the field supervisors in every *ri*, or natural village, in which a rural sample enumeration district (ED) was found, 120 in all. There are plans, under separate UNFPA funding, to supplement the original data from secondary sources and to analyze in detail the relationship between community characteristics and individual fertility and family planning behaviour through a linkage of the two sources of data: the community and the individual surveys.

Discussion of the community survey, therefore, will be reserved for the report planned for the new project to run for about sixteen months starting in mid-1977.

2.2 PRE-TEST, INSTRUCTION MANUAL AND TRANSLATION

The drafting and finalization of the household schedule and the individual questionnaire took place from April through July, 1974. After consultations between local experts, the project staff and the WFS professional staff, a draft of the questionnaire was prepared for the first pre-test.

2.2.1 PRE-TEST

- 1) The first pre-test (held on June 21-26, 1974) was conducted in *Daejeon*, a middle-sized city, and *Yusong Mun*, a near by rural community, in *Chungnam* Province to the South of Seoul, the capital city.

Ten female interviewers with previous experience in fertility and family planning surveys were recruited and instructed in the use of the household and individual questionnaires for three days. It became clear during the training that the pregnancy history and the fertility planning sections required further revisions, and so they were excluded from the pre-test.

Two hundred interviews were completed with the full household schedule and the curtailed individual questionnaire. Each day meetings were held to detect problems of wording, question sequence, format, timing comprehensibility, acceptability, etc. These meetings were used as training sessions to supplement the 3-day formal training the interviewers received prior to the pre-test and also to experiment with the revisions called for in the questionnaire design.

Maps-prototypes to be used in the main survey-were provided by the Bureau of Statistics for the purpose of identifying boundaries of census enumeration districts in which pre-test interviews were assigned. The senior staff tested these maps for unambiguous boundary lines and sufficient number of identifiable landmarks. A number of them were found to be inadequate, and this information was conveyed to the Bureau of Statistics so that they could improve their mapping operation for the main survey.

The first pre-test version of the individual questionnaire, even without the sections on pregnancy history and fertility planning, was found to be too long, requiring more than 60 minutes to administer. Questions on migration, attitude items on induced abortion (the scale items from the WFS Abortion Module), several questions on the cost of contraceptive supplies,

questions on kinship involvement, among others, were removed or reduced in an attempt to shorten the instrument to a more manageable length.

Some of the questions relating to parental expectation with regard to children, adapted from the Economic Module, were difficult to convey not only to the respondents but even to the interviewers, because of the questions' impersonal reference to parents in general. They were reworded, as they are now in the final version, to refer to the respondents' own expectations.

The Coombs' scales, introduced experimentally, were found to be usable. The interviewers could be taught how to administer the questions, and they were understood and accepted by the respondents. Their responses appeared reasonable.

Respondents found it hard to recall dates of separations from their husbands. The pre-test suggested the advisability of keying periods of separation to pregnancy intervals and the use of a chart like the one developed for the main survey.

The questions on extended family relationships did not differentiate between husband's and wife's relatives, causing considerable confusion in the respondents' minds as to which relatives to include. The pre-test suggested the advisability of restricting the questions to the parents and distinguishing between the respondent's own parents and her in-laws.

There were other problems; for example, the questions about contraceptive methods recommended by the WFS Core were found cumbersome, and divorces were reluctant to talk about their ex-husbands. Most of these were handled as problems of interviewing technique and dealt with in the training sessions.

- 2) The second pre-test, held on July 2-7, 1974, was conducted in *Chuncheon*, another middle-sized city, and *Chunseong-gun* its rural hinterland area, in *Gangweon* Province, in a mountain valley to the east of Seoul.

Five of the interviewers from the first pre-test, chosen for their demonstrated ability and continued availability, were joined by five female research staff members of the KIFP to serve as the interviewing team for the second pre-test. The team was instructed in the use of the revised household schedule and the individual questionnaire, complete with both the pregnancy history and the fertility planning sections, in a one-day session in Seoul. Further training continued in the field following the completion of at least one interview each.

Two hundred and fifty interviews were completed. As before, daily feed-back sessions were conducted to learn of problems and to discuss ways to meet them. Except for minor revisions in question wording and skip instructions, the instruments were judged to be workable and were also of manageable length. The household schedules averaged about 15-20 minutes to administer, and the individual questionnaires-with all sections included-took about 60 minutes on the average.

Both the pregnancy history chart (described in detail in Appendix 4) and the skip instructions of the section on fertility planning worked smoothly. The pre-test experience with the latter section suggested the advisability of adopting the colour scheme recommended in the WFS Core to further reduce the apparent complexity of this section.

This pre-test mobilized all those who were to serve as senior supervisors in the main survey and was used as a means to familiarize them with both the survey instruments and field conditions.

One persistent field problem that was revealed during the pretests was the difficulty of obtaining privacy for the individual interview. In the training sessions for the main survey, this problem was given special attention and the interviewers were instructed to make every effort before the start of the interview to get others to leave.

2.2.2 INSTRUCTION MANUALS

Comprehensive, detailed instructions in the use of the household schedule and the individual questionnaire were prepared. Given the relative complexity of the survey instruments, the instructions were prepared, question by question, in great detail, stating the question objectives - in a manner consistent with WFS objectives, where common questions were involved - and illustrating the use of the many charts and skip instructions included in these instruments.

These instructions were bound together in loose leaf form (to permit easy replacement or supplementation, as needed) as part of the Interviewers' Manual, distributed to each interviewer and used in training as a text as well as a reference for the interviewers in the field.

2.2.3 TRANSLATION

All the questionnaires and the supporting documents were drafted in English. The translation into Korean was done by several senior staff from the cooperating agencies: BOS, and KIFF. Translations were checked for accuracy by every translator checking each other's work.

In the case of the household schedule and the individual questionnaire, a further independent check was done by back-translation. There were no major mistranslations by the original translators, though numerous refinements - some extremely subtle - were required in the effort to produce a Korean version as faithful to the English original as possible. In a handful of instances, the English wordings were changed slightly to reflect the Korean wordings when it was mutually agreed that there was no way to render into Korean the exact English original.

2.3 THE SAMPLE

2.3.1 SAMPLE SIZE⁶⁾

One of the basic aims of the 1974 Korean National Fertility Survey, as noted earlier, was to obtain reliable estimates of vital rates-fertility, in particular.

Figures based on simple random sampling indicated that a sample size of at least 15,000 to 20,000 households was needed to obtain precisions within 5 per cent for estimating the crude birth rate, and within 10 per cent for estimating the age specific fertility rates.

The complexity of the individual questionnaire, however, precluded the option of our using it on too large a sample lest the non-sampling error exceed the sampling error. Hence, it was decided to use the simpler households schedule, with its fertility questions, on a large a sample as the

⁶⁾ See "Appendix 1: Sample Size Required for Korean National Fertility Survey (prepared by J.S. park)," in "General Features of Sampling procedure for the World Fertility Survey, Korea, 1974 (edited by Ehn Hyun Choe)," In Journal of Family Planning Studies, Seoul: Korean Institute for Family Planning Vol.3 (April, 1976), pp.84-118.

project could bear without adversely affecting the quality of the operation and restrict the use of the more complex individual questionnaire on a much smaller subsample of the former. The latter could tolerate a substantially smaller sample, as its main aim would be to provide data of use in studying the correlates and patterns of fertility and family planning behaviour rather than in providing estimates of current rates.

On the advice of both the local consultant and the WFS professional staff, it was concluded that samples of about 18,000 for the household survey and about 5,000 for the individual survey would meet the objectives, and would be within manageable limits of the survey capacities of the executing agencies.

2.3.2 SAMPLE DESIGN

The sample design for the 1974 Korean National Fertility Survey aimed for a self-weighting, nationally representative, probability sample, using basically a two-stage design for the household survey with a further sampling stage for the individual survey. Census enumeration districts (ED's) were used as the primary sampling units (PSU's), with households in the selected PSU's constituting the ultimate sampling units. The definition of a household, as used in the population census and applied in this survey, is a group of persons who share both living quarters and expenditure. By this definition, persons sharing living quarters could belong to a different household if they happened not to share expenditure. The first two stages of selection was designed to obtain about 18,000 households for the household survey, and the third stage was designed to obtain about 5,000 eligible respondents for the individual survey, where eligibility was defined in terms of women under 50 years old who had ever been married.

2.3.3 SAMPLING FRAME

The list of census enumeration districts (ED's), available on the computer at the Bureau of Statistics, with the counts of households and population from the 1970 Population and Housing Census, served as the sampling frame. This was a convenient frame on at least two counts: (1) the average size of the ED's was about 80 households, a useful size of unit from the points of view of both sampling and field work efficiency, and (2) each ED had an accompanying map prepared in 1970, which could be easily updated.

The institutional population and the most inaccessible islands were excluded from the frame; the resulting "effective" frame covered about 97.6 per cent of the total population and nearly all (99.8%) of the ever-married women under 50 years of age.⁷⁾

2.3.4 SAMPLING FRACTION OF HOUSEHOLDS

The basic sampling fraction for the study was determined as follows; given the growth of population during 1970-74, a sampling fraction using 17,000 households as the numerator over the total number of households in 1970 was thought sufficient to produce the required household sample size of 18,000; hence the sampling fraction was:

$$\frac{17,000}{5,846,288} = \frac{1}{344}$$

⁷⁾ The 75,771 ED's included in the effective frame contained, according to the 1970 Census, 5,846,288 households and about 5,000,000 ever-married women under age 50.

2.3.5 FIRST STAGE: SAMPLING OF ED's

Conveniently, all the ED's were listed separately for the urban and the rural sectors and within each sector by administrative units—from the largest to the smallest units, all in geographical sequence, so that an urban-rural and an implicit geographical stratification was built into the list as it was filed. There was no attempt to stratify the ED's any further, since the urban-rural split in population distribution was about 40-60 and a systematic application of an interval of selection to the existing list would have produced a sample of ED's spread evenly over the population of the entire nation without necessarily raising travel costs, as compared to the costs of a more clustered sample design. (In retrospect, the field cost for this project probably did not justify the sampling efficiency gained. This view can be tested later by comparison with other fertility surveys, conducted recently in Korea, using stratified, area sampling designs.)

The distribution of households in the ED's around the mean of 80 was as follows: 90 per cent of the ED's contained 50 to 120 households, 6 per cent contained less than 50 and 4 per cent contained 120 or more. To keep the assignments in the sample places fairly uniform, a "combine and split" operation was introduced: those ED's with less than 50 households were combined with neighbouring ED's so that together they would contain at least 50 households and those ED's that contained 120 or more households—either originally or after reconstitution by combining were "split" by the assignment of measures of size (M) as follows:

Number of households	Measures of size (M)
50-119	1
120-219	2
220-289	3
290-389	4
390-459	5

These procedures produced 76,061 measures of size (32,748 in the urban and 43,313 in the rural sectors) from the 75,811 original ED's (32,569 in the urban and 43,251 in the rural sectors).

The ED's were selected by systematic sampling with a random start from the list of measures of size, so that each ED was selected with probability proportional to its measure of size. Two intervals of selection were chosen, I=171 for the urban sector and I=342 for the rural sector. Thus the probability of selection was twice as large for the urban ED's as for the rural ED's. The aim was to get a greater spread of the ultimate sample of households in the urban sector, where ED's tend to be physically smaller but more densely populated than the ED's in the rural sector. In order to maintain a self-weighting model this difference is corrected in the second stage of selection.

The systematic selection from the rural sector yielded 127 ED's. Thus, the probability of selection of the *i*th rural ED was:

$$f_i = \frac{127M_i}{\sum M_i} = \frac{127M_i}{43,313} \approx \frac{M_i}{341}$$

The urban sector yielded 192 ED's in the sample, with a corresponding probability of selection of the *i*th urban ED of:

$$f'_i = \frac{192M'_i}{\sum M'_i} = \frac{192M'_i}{32,748} \approx \frac{M'_i}{171}$$

2.3.6 MAPPING AND LISTING

Thirty staff members from the Bureau of Statistics and the Korean Institute for Family Planning were trained and sent, over a two-month period (July and August), to each of the 319 sample ED's to update the maps originally prepared in 1970. The boundaries were checked and revised on the basis of changes that may have occurred since the 1970 Census and landmarks—structures, topographical features, etc.—confirmed or added as needed. The technical staff of the BOS checked each map upon completion, sending it back, if necessary, for any corrections or clarifications. There was no relisting of the households at this stage because of the shortage of time before the actual field work planned for the last quarter of the year.

Listing of the households was carried out in each sample ED at the time of the actual survey, starting in late September, 1974, by each team of interviewers supervised by their respective field supervisors. The sequence of activities for each team, one ED at a time, was as follows:

- 1) The ED was located and its exact boundary identified, with the use of the updated map as guide but revising it further as needed. The more difficult problems in this effort were immediately referred back to the technical staff of the BOS for quick resolution.
- 2) All the living quarters (LQ's) within the ED boundary were listed and serial numbers assigned to them in some geographical order by the field supervisor.
- 3) The supervisor assigned the LQ's to the interviewers, who visited them to list the households occupying them. Each household was assigned a number within each LQ, the listing consisting of the name of the head of the household, its address, and the number of household members who were usual resident there and/or "slept there" the night before.
- 4) The supervisor consolidated the household listings prepared by the interviewers into a master list for the ED, showing the households by LQ's arranged in some geographical sequence and indicating the size of each household as follows:

LQ NO.	HH. NO.	Number of household members					
		1	2	3	4
001	01	x					
	02			x			
002	01				x		
003	01						x
	02	x					
	03		x				

2.3.7 SECOND STAGE: SELECTION OF HOUSEHOLDS

The consolidated household list was ordered by household size and a systematic sample taken with random start and probability of selection.

$$g_i = 1/M_i$$

for the *i*th rural ED, and probability of selection

$$g'_i = 1/2M'_i$$

for the *i*th urban ED. (Note that for most ED's $M_i=1$, corresponding to a complete take of rural ED's). Hence the overall probability of selecting a rural household was

$$f_i \cdot g_i = \frac{127M_i}{\sum M_i} \cdot \frac{1}{M_i} = \frac{127}{\sum M_i} = \frac{127}{43,313} \approx \frac{1}{341}$$

and the overall probability of selecting an urban household was

$$f'_i \cdot g'_i = \frac{192M'_i}{\sum M'_i} \cdot \frac{1}{2M'_i} = \frac{96}{\sum M'_i} = \frac{96}{32,748} \approx \frac{1}{341}$$

an overall sampling fraction slightly higher than that suggested in sub-section 2.3.4 above.

2.3.8 THIRD STAGE: SELECTION OF INDIVIDUALS

A subsample of 6,000 households was expected to yield the desired number of 5,000 eligible women for the individual survey. This was based on an expected 95 per cent response rate, estimated from similar surveys in Korea, and an average of 0.876 eligible women per household, estimated from the 1970 census. Thus,

$$6,000 \times 0.95 \times 0.876 \approx 5,000.$$

Hence the subsampling fraction for the individual survey was set at ($h_i=1/3$) of the sample of households, with the expectation of obtaining (18,000 \times 1/3=6,000) households, in which every eligible woman would be subject to the individual survey. Again the sub-sample was selected by systematic sampling with a random start, with interval $I=3$.

2.3.9 DETAILS OF SAMPLING IMPLEMENTATION

Each interviewer was assigned a set of households to be visited either for the household survey alone or for both the household and the individual surveys. The household survey was taken with any responsible adult member of the given household. Up to about three callbacks were made during the team's stay in the ED if no responsible adults could be contacted on earlier visits.

If in a given LQ, a non-listed household was found either because it was originally missed or a new household had moved in or been formed in the brief interim since the listing, that household was subject to the household survey along with the original household that was listed. If a household had moved out by this time, it was not followed to its new address unless it was in an ED where all households were subject to the household survey (a rural ED with a measure of size of 1) and it had moved to another address within the ED. These rules permitted the inclusion in the sample of newly formed and newly moved-in households. (Those moving out had a chance of being included at their destinations.) Such cases, however, could not be numerous, given the brevity of the interval between initial listing and interviewing. The interval was a day for most ED's and two to three days only in the most unusual instances.

In the subsample of households subject to the individual survey, the individual questionnaire was administered immediately following the household survey to every eligible woman, if any, who happened to have "slept there" the night before. Up to about three callbacks were made during the team's stay in the ED if any of the eligible women could not be interviewed on earlier visits. There was no attempt made to follow-up a woman who left the ED after the first visit to the household.

If a newly formed or newly moved-in household or a previously missed household was found in an LQ where a household was subject to the individual survey, both the household and the individual surveys (assuming presence of eligible women) were taken.

In 5 ED's, where there were many more households than anticipated, varying subsampling fractions were employed to reduce the work load to manageable limits: 1/2 in two ED's, 3/5 in one ED, and as much as 1/4 in one ED where several apartment buildings had been constructed near a booming industrial site. The reductions in the sample "take" in these ED's were made by either increasing the interval of selection or subselecting segments and applying longer intervals of selection than originally called for. The interviews obtained from these ED's were weighted back up by duplication as needed in the final data files.

2.3.10 THE RESULTS OF SAMPLING IMPLEMENTATION

The application in the field of the foregoing procedures yielded samples of 21,248 and 6,849 households for the households and the individual surveys, respectively. Household schedules were completed in 20,932 or 95.6 per cent, of the total household sample. Of the 6,849 households subject potentially to the individual survey, 5,271 households, or 77.0 per cent, were known to contain at least one eligible woman. In fact, 5,724 eligible women were identified in the 5,271 households and 5,417 (94.6%) of them successfully interviewed.

Outcome	Household Sample		Individual Sample	
	Number	per cent	Number	per cent
All Cases	21,248	100.0	5,724	100.0
Completed	20,932	95.6	5,417	94.6
Partially completed	12	0.1	10	0.2
Not completed	304	1.4(100.0)	297	5.2(100.0)
Not at home	229	1.1(75.3)	132	2.3(44.4)
Refusal	35	0.2(11.5)	19	0.3(6.4)
Other ^{a)}	40	0.2(13.2)	51	1.0(17.2)
No call-back	--	--	95	1.6(32.0)

^{a)} Includes "no competent respondent," "respondent was ill," etc.

The larger than expected "take" of households for the household survey and the relatively fewer eligible respondents for the individual survey suggest that the "nuclearization" of the families has progressed at a fairly rapid pace in recent years- the consequence being more independent households but fewer members in each⁸⁾

The response rates for the household survey and the individual survey were high, as can be seen in the summary below of how the samples were disposed: About 95 per cent of both the

⁸⁾ The comparison of the censuses of 1970 and 1975 confirms this trend, the increase in the number of households during 1970-75 was 2.5 per cent, substantially greater than the growth of the total population (1.75%) and the average household size declined from about 5.0 in 1970 to about 4.8 in 1975

household and the individual samples yielded completed interviews with only a handful (less than half a per cent) of outright refusals. The small percentages of samples from which interviews could not be obtained were due primarily to difficulties in locating a responsible informant in the case of the household survey and the appropriate respondent (i.e., eligible woman) in the case of the individual survey.

A subsequent review of the field work revealed the following minor errors in implementation;

- 1) Inclusion of households outside of the ED (47 cases)
- 2) Duplicate listing of household (9 cases)
- 3) A series of minor errors in the application of intervals;
 - (a) Use of a wrong interval of selection
 - (b) Use of a wrong random start
 - (c) Misapplication of the interval of selection

All erroneously selected households and duplicates were removed, and suitable adjustments made to the data files.

2.4 THE ORGANIZATION AND EXECUTION OF THE FIELD WORK

The Korean Institute for Family Planning (KIFP) was charged with the responsibility of recruiting and training the field staff and actually mounting the survey in the field. To facilitate the various tasks during this important phase of the project, the survey headquarters were set up at the KIFP from August through December 1974.

2.4.1 RECRUITMENT OF THE FIELD PERSONNEL

Field personnel for this survey had to be recruited either by secondment from the two executing agencies or other institutions or by open advertisement. Three levels of field personnel were required; field supervisors, field editors, and interviewers.

FIELD SUPERVISORS

In early August 1974, 22 persons were recruited to serve as field supervisors. Seven were seconded from the BOS, three from the KIFP, and the remainder from the local universities and other outside agencies. Supported by the pre-test experience, tradition was broken by deliberately recruiting 5 females to serve as field supervisors, heretofore customarily regarded as a male job. Most recruits had supervisory experience and proven leadership qualities and many had previous survey experience.

FIELD EDITORS AND INTERVIEWERS

The primary recruitment sources for the field editors and interviewers were advertisements

in a Seoul newspaper. Given the cultural and linguistic homogeneity of the Korean population, interviews could be recruited centrally in Seoul. Female applicants over 22 years old with at least high school education were sought. Marital status was not specified. All applicants were required to take a written examination, which tested their general intelligence, general knowledge about surveys, and ability to write legibly. They were interviewed by a selection committee to evaluate their verbal skills, poise, appearance, grooming, and suitability for team work and travel over an extended period of time.

From over 300 applicants, 135 were selected, and 129 actually accepted the offer of employment. Twenty one field editors were eventually selected from among the 129 trainees on the basis of superior performance during training. Characteristics of the field supervisors, field editors and interviewers are summarized in the following table:

Characteristics	Field Supervisors	Field Editors	Interviewers
Total	22	21	108
Age:			
23-24	9	19	35
25-29	14	52	50
30-34	36	24	15
35 and over	41	5	—
Total	100%	100%	100%
Median Age	33.8	28.0	26.5
Education:			
High school	—	29	56
College	14	33	28
Graduate school	86	38	16
Total	100%	100%	100%
Marital Status:			
Single	41	52	76
Married	59	48	24
Total	100%	100%	100%

2.4.2 TRAINING OF FIELD PERSONNEL

The training program was implemented in three stages: trainers' training (3 days), field supervisors' training (7 days), and interviewers' training (18 days). The curricula for the training sessions of the field supervisors and the interviewers are reproduced in Appendix 6. It should be added that the field supervisors participated in the interviewer's training sessions as well as in the sessions provided solely for them. The trainer's instruction consisted of a review of the survey instruments and the field procedures to be used for this survey. Each trainer's assignments were fixed and clarified also at this time.

The basic documents used in the training were the Supervisor's Manual for the field supervisors and the Interviewer's Manual for the field supervisors, the field editors, and the interviewers. The tables of contents of these manuals are reproduced in Appendix 5. They were both modelled after the corresponding WFS documents but supplemented with materials needed for the specific survey procedures—sampling, in particular—and instruments adopted for the Korean National Fertility Survey.

Tape recorders and video tapes were used as training aids. The tape recorders were used to record practice interviews, which were played back for instructional purposes. The video tapes were used to demonstrate the setting of an actual interview and the use of the more complicated sections of the individual questionnaire.

Other training aids included the use of "blown-up" versions of several of the charts from the individual questionnaire and the recruitment of married women from the local community to serve as "live" practice respondents.

The interviewers had four days of practice in the field during the training period. The completed interviews were reviewed and discussed in detail after each field practice. At least 8 practice interviews were taken by each trainee. The last two days of practice included ED listing and sampling as well as administering the household schedules and the individual questionnaires.

One shortcoming was the very little time devoted to field editing procedures and supervised practice in editing. Possibly another three days of intensive training for the supervisors and the field editors specifically on editing procedures would have been beneficial. A little more practice in ED listing and subsampling procedures could also have reduced difficulties encountered later by the office staff in correcting the errors in implementation committed by the field staff. The errors were minor, as can be judged from the review of the sampling procedures, but they could have been avoided.

2.4.3 FIELD WORK AND SUPERVISION

The so-called "team approach" recommended by WFS was adopted in organizing the field work, as in all previous major fertility surveys in Korea. A diagrammatic view of the field work organization is shown in Figure 4.

Twenty-one teams were organized with each team having the following composition: 1 supervisor, 1 field editor, and 5-6 interviewers. The teams were assigned to one of three zones into which the whole country was divided for operational and supervisory efficiency:

- Zone A. Eastern and South Central Provinces; Gangwon, Chungbuk, and Gyungbuk
- Zone B. Southern and South Western Provinces; Jeonnam, Jeonbuk, Gyungnam, and Jeju
- Zone C. West Central Provinces; Chungnam, Gyunggi, and Seoul Special City

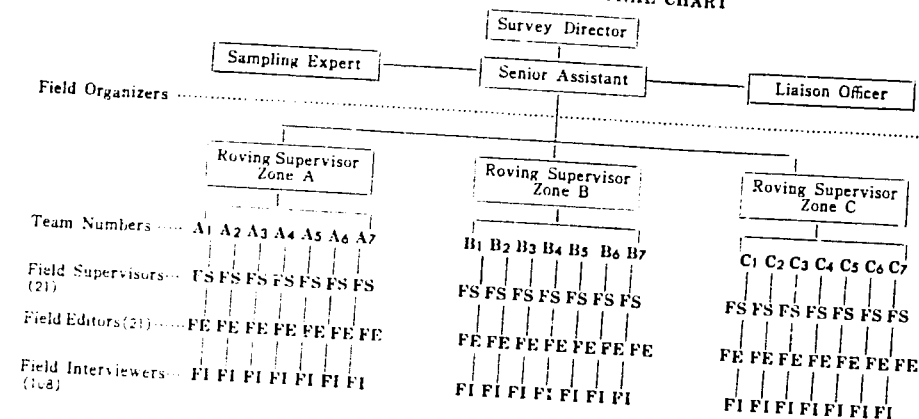

A roving supervisor was assigned to each zone, to circulate continuously among the teams serving as a "trouble-shooter" and maintaining quality control. The Field Director and one senior officer served as central supervisors, stationed at the field headquarters in Seoul but travelling frequently to monitor the field work.

One of the KIFP officers initially recruited and trained as a field supervisor was assigned to serve as the central liaison officer, stationed in Seoul to receive calls and inquiries from the field.

The sampling expert from the BOS was on call for any field problems related to sampling. If necessary, he too travelled to the field to deal with the more difficult problems.

The team itineraries were fixed at the outset as to dates and locations and were followed closely by each team during the entire field operation. The central and the roving supervisors could travel to exactly where the teams were expected and locate them without having to contact

FIGURE 4. FIELD WORK ORGANIZATIONAL CHART

them before-hand. The element of surprise could be expected to improve quality control.

The day-to-day supervision of the field work was carried out by the field supervisors. Their responsibilities were numerous:

Arrange the transportation and accommodation of the team members;

- Gain entry to the communities-talking to local officials if necessary;
- Locate the sample EDs;
- Check the maps;
- Coordinate the listing operation;
- Select the households for both the household and the individual surveys;
- Assign the households to the interviewers;
- Scrutinize the completed interviews;
- Check the sample addresses, including spot-checks;
- Assist the field editor in editing, as needed;
- Assign reinterviews to the field editor;
- Complete the control sheets, shipping all materials to the headquarters upon completion of each ED;
- Maintain contact with the central headquarters, calling for central staff assistance as needed;
- Maintain the team morale;
- Administer the Community survey in the rural places.

The following control sheets were prepared by each field supervisor:

- Summary of Household Survey Interviewing Activities
- Summary of Individual Survey Interviewing Activities
- Summary Report by ED

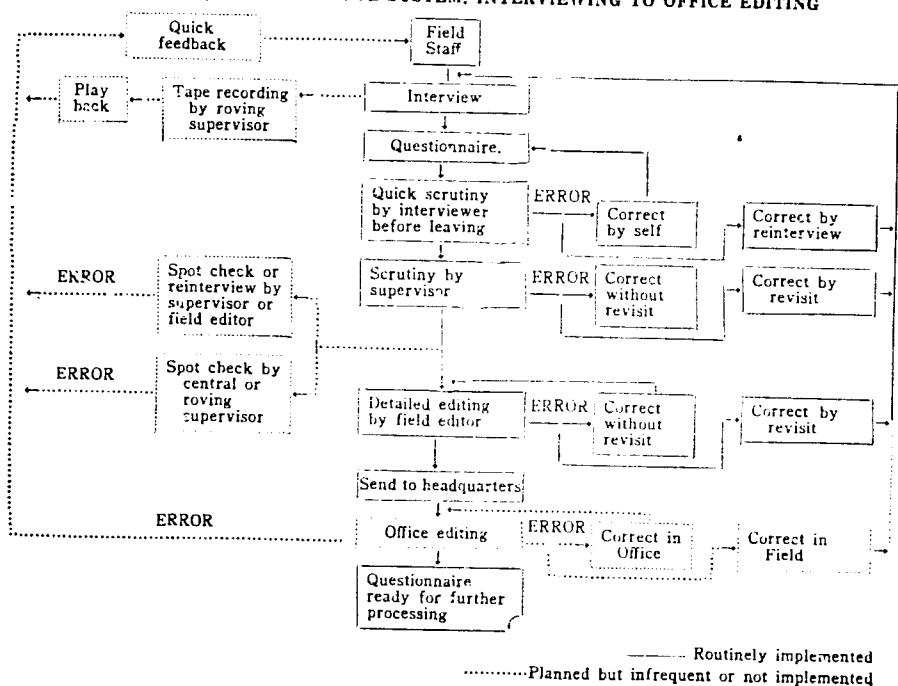

- Daily Summary Report of Events from Completed Interviews
- Household Listing Sheet
- Sample Selection Sheet

The field editors, often assisted by their supervisors, edited all interviews completed by their respective team interviewers at the end of each day, whenever possible. Supported by their supervisors, they held feed-back sessions with the interviewers to correct any errors in interviewing and recording. Some return visits were requested if the errors were difficult to resolve. They sometimes took the more difficult interviews if the regular interviewers failed in their efforts. They were instructed to reinterview some of the cases as a quality control measure, but few actually did so.

The roving supervisors carried with them cassette tape recorders for evaluation purposes, but their use was limited by the lack of experience and training in their use.

The plan to do systematic office editing throughout the field work failed to materialize due to shortage of personnel at the headquarters. The Field Director and WFS consultants did some initial office editing which brought out the more common errors of execution being committed by the interviewers and field editors. However the Field Director and his senior assistant were called into the field for supervision so frequently that they had little time to do much else at headquarters. These staffs were more useful as trouble-shooters than as quality control agents,

FIGURE 5. QUALITY CONTROL SYSTEM: INTERVIEWING TO OFFICE EDITING

although in the process of trouble-shooting many errors were detected and corrected. High level supervision of systematic quality control and more explicit plans for office editing are recommended for future surveys.

The quality control system originally planned for the Korean survey is diagrammed in Figure 5. Those activities that were weak, if not virtually absent, are shown in boxes or arrows with broken lines.

2.4.4 CASE LOAD AND LENGTH OF INTERVIEWS

The 109 interviewers completed approximately 20,327 household schedules and 5,265 individual questionnaires over a 75 day period from September 16 to December 5, 1974. The average load was thus 186.5 household schedules and 48.3 individual questionnaires for the entire period for each interviewer, and 2.5 household schedules and 0.6 individual questionnaires per day per interviewer. These grossly underestimate the actual work efficiency of the teams in that at least one day a week was a day of rest and travel time between sample ED's varied considerably. Besides, field conditions faced by the teams and individual interviewers varied considerably. In the absence of more detailed documentation, however, the above gross averages must suffice.

The time of completion of the household schedules had the following distribution:

Number of minutes	
Under 10 minutes	42
10-14 minutes	34
15-19 minutes	14
20 minutes or more	10
All schedules	100%
Mean:	11.5 minutes

The individual questionnaires took substantially longer. The distribution was as follows:

Number of minutes	
Under 30 minutes	3
30-39 minutes	11
40-49 minutes	20
50-59 minutes	22
60-69 minutes	17
70-79 minutes	11
80-89 minutes	5
90 minutes or more	11
All questionnaires	100%
Mean:	59.5 minutes
Median:	56.4 minutes

2.5 MANUAL EDITING, CODING AND KEY-PUNCHING

As the completed interviews and control sheets were received at the headquarters from the teams scattered throughout the country, the central supervisors, the liaison officer, and the sampling expert-assisted by several clerks-scrutinized the interviews and the sample selection sheets to uncover quickly any major errors of execution so that corrective measures could be instituted while the teams were still in the field. This was done carefully at least during the first few weeks of the field period, but the heavy demand in the field made it difficult for the central staff to continue this activity throughout the entire field period. The bulk of the checking, therefore, took place only after the field work was completed. Several problems discovered then had to be resolved by return to the field by the central staff several months after the field period.

The clerks checked the completed interviews against the control sheets to make sure that all could be accounted for and then filed by binding the household schedules and the individual questionnaires separately by ED units. In this way, the FD-by-ED progress of the field work could be recorded and the completed interviews themselves made easily accessible for later processing.

2.5.1 PREPARATION OF THE CODES

The codes were prepared in consultation with the WFS professional staff to ensure that international comparability would be maintained and that variables needed for the standard table of the Country Report would be derived. Four card types were prepared for the household schedule and 15 for the individual questionnaire. The basic principle followed in the construction of the codes was to code the data in their raw forms and use recode programs on the computer to bring them together as needed for tabulation. The aim was to maximize the utility of the data for further analysis beyond the First Country Report. Later, however, in order to facilitate the production of the tables required for the First Country Report, some manual recoding (e.g., the Pattern of Contraceptive Use) was added to the original coding scheme.

2.5.2 MANUAL EDITING AND CODING

Thirty-five of the regular coders at the BOS were mobilized to edit and code the 20,000 or so household schedules. In addition, 20 coders were recruited from among the interviewers to process the 5,000 or so individual questionnaires. The regular coding supervisor at the BOS supervised the former, and the liaison officer during the field work was assigned to serve as supervisor of the 20 individual survey coders.

The editing and coding was done in stages: manual editing, solar data conversion, special coding of the more difficult codes, and producing coding.

The editing consisted basically of checking to see that all skip instructions were properly followed and that every question appropriate to a case was asked or accounted for. Also dates given in lunar form were converted to the solar calendar using the solar date conversion chart prepared by the KIFP. All dates-after conversion to the solar calendar-were checked for consistency between events: the woman's birth date, her date of marriage, and her children's birth

dates, for example. In a small number of cases where months were missing, one of four seasons was randomly assigned and the middle month of the season imputed. For missing days, 15 was imputed.

The individual Questionnaires were systematically checked for consistency between responses in Section 2 (Maternity History), Section 4 (Contraceptive knowledge and Practice), and Section 5 (Fertility Planning). All editing activities, including the solar date conversion, were verified by the coders checking each other's work.

The more difficult codes such as occupation and open-ended questions were done by a special team of coders before producing coding and checked independently on a 100 per cent basis.

Upon completion of the manual edit and special coding, all coders went into production coding, going through each interview card type by card type. The original coding was verified on a 100 per cent basis.

The supervisors checked the completed production coding sheets to ensure that all ED's and all cases in a given ED had been included.

The coding sheets were then key punched, followed by 100 per cent verification of the punched cards on the verifier. Finally, the card images were transferred onto magnetic tape for further processing.

2.6 PREPARATION OF CLEAN TAPES, RECODING AND TABULATION

Before the tapes could be used for tabulation, they were subject to further editing and adjustment to correct for errors or departures from the original sample design during field implementation.

Computer editing consisted of range checks for illegal codes, consistency checks between codes, arithmetic checks of calculations such as exact age, and interval checks for overlapping events in the birth and marriage history. The CONCOR computer edit package recommended by WFS was not available for use in Korea, and the computer editing involved considerable assistance from the WFS London staff. The programming of edit specifications proved troublesome and extremely time consuming, and delayed the progress of the project by at least 5 months.

Separate tapes, or files, of the computer-edited household and individual questionnaire data were adjusted for a small number of large ED's where a smaller sampling fraction was employed. The relevant data were weighted to the original sampling rate by duplication. The files were also checked for completeness and consistency between the household and individual data.

Finally a recode tape and a tape of marginal frequencies to check the tabulations were prepared. The recode tape provided input for the COCENTS tabulation program, which was adapted to produce the standard tables for this report. Special programs were prepared by local programmers to produce tables that were not in the WFS guidelines but were of special local interest.

CHAPTER 3

COMMENTARY ON THE MAIN FINDINGS

3.1 GENERAL INTRODUCTION

Intensive analysis of the results from a complex study such as the Korean National Fertility Survey is a very lengthy process. It requires a detailed appraisal of the quality of the data obtained, with possible adjustments to minimize or correct deficiencies. It also involves the application of progressively more refined demographic and statistical techniques in the attempt to elucidate inter-relationships, as well as in depth studies of particular issues such as fertility change. Faced with the probability that exhaustive analysis of data might delay publication of major findings by several years, the WFS adopted a policy that requires participating countries to publish their basic results as soon as possible in the form of tables with a short accompanying text. Toward this end, detailed guidelines as to the contents of a first report have been provided by the WFS.⁹⁾

This chapter, following WFS recommendations, takes the form of a broad and preliminary review, which leaves many topics incompletely explored and many questions unanswered. While a large number of tables have been prepared and published in this report, no effort has been made to comment on each of them, as this would be tedious and serves little purpose. Instead, the commentary has been confined to the major points that emerge from the data, leaving the specialist reader to examine the tables in detail as interests dictate. Despite the necessarily tentative nature of the discussion, the review is not intended to be purely descriptive. Rather, preliminary interpretations and explanations are presented, wherever the importance of the topic, the nature of the data, or the needs of policy makers justify such an approach. It is expected, however, that further analysis in due course will yield additional as well as more definite conclusions than those drawn in this first report.

This chapter is organized into ten sections; a general introduction, eight substantive sections devoted to major findings from the household schedules and the individual interviews, and concluding comments. Except for a few tables that are based on special tabulations made for this report, the tables on which the substantive comments are selectively based are presented at the end of this chapter. They bear the same numbering system as that recommended by WFS in the *Guidelines for Country Report No. 1*, to permit easy cross-reference between the first reports of all participating countries. Included are several tables unique to the Korean survey. In the text, reference is made to the tables wherever appropriate. In addition, some key findings are presented in this chapter in the form of summary tables, with cross-references-if appropriate-to the original, detailed tables from which they are drawn. In each case, a distinction is made as to whether it is based on the household survey (HHS) or the individual survey (KNFS) unless it is clear from the context in which it is presented. These summary tables, unlike the original tables, do not usually show the frequencies on which the percentages and the means are based. As a safeguard for the reader, the following symbols have been used for the summary tables unless otherwise noted. Where the frequency on which a percentage or a mean is based is less than 50 cases, the appropriate cell entry is enclosed in parentheses. If fewer than 20 cases, an asterisk (*) is entered; and a dash (-) signifies no cases or a non-zero percentage less than 0.5 when the percentage are rounded to the nearest integer.

9) See *Guidelines for Country Report No. 1*. WFS/TECH. 225, 13th August 1975, p. 112 and appendices

The effective samples used in the basic tabulations are: 21,253 households, with 17,157 ever-married women in the ages 15-49, from the household survey and 5,420 ever-married women in the ages 15-49 for the individual survey.

The sampling errors for the present survey were not computed in time to be incorporated into the discussion of findings. They are presented for some of the key variables of the study in Appendix 8 for those readers who wish to consult them. A more detailed presentation and interpretation of sampling errors will be published at a later date.

3.2 POPULATION ENUMERATED IN THE HOUSEHOLD SCHEDULE

3.2.1 INTRODUCTION

In Korea, the household survey was based on a sample of sufficient size to yield national, if not regional, estimates of fertility and mortality. In other words, the household survey in Korea was used not only as an instrument to identify the women eligible for the individual survey but also as an important source of data on vital statistics sorely needed in Korea. Furthermore, as an important by-product, the household survey yields data on age and sex composition of the population which can be compared with available census data to assess the representativeness of the sample vis-a-vis the national population from which it was drawn. Also possible are comparisons of distributions by size of community, marital status, and educational attainment.

This listing of the household members was done on both a *de jure* and a *de facto* basis, following WFS recommendations. Usual household members absent the previous night were listed in addition to all persons who "slept" in the household the night before, including temporary visitors. A total of 104,893 persons were listed on the household schedules obtained from 21,253 sample households. Of these, 103,462 persons, or 98.6 per cent, were usual residents (*de jure*), thought not necessarily present the night before, 1,431 persons were temporary visitors.

The tabulations from the household survey are based on all listed persons (both *de jure* and *de facto*, totalling 104,893) unless otherwise noted. When data are compared with earlier censuses, the *de jure* population (103,462 persons) is used as base for comparability since the Korean censuses are taken on a *de jure* basis.

3.2.2 OVERALL POPULATION COMPOSITION

Table 1 shows the age-sex composition of the *de jure* population from the 1974 household survey as compared to the 1966 and 1970 population censuses. The age distributions from the 1974 survey and the 1970 census are remarkably close for both males and females with one notable exception in the ages 20-24 for the males. There is an undercount of the latter in the 1974 survey due to the exclusion from the sampling frame of the special enumeration districts containing military installations. This is reflected further in the comparison of the sex ratios between the survey and the census: for ages 20-24, the sex ratio is as low as 70 in the survey as compared to 106 in the 1970 census.

Both the 1974 survey and the 1970 census show relatively fewer persons in the ages under 10 as compared to the 1966 census. This is consistent with the decline in the crude birth rate during the past decade, from 35 in 1966 to 27 in 1974. The differences in age distribution between the 1974 survey and the 1966 census are shown graphically by five-year age groups in Figure 6.

FIGURE 6. AGE-SEX COMPOSITION FOR THE SURVEY COMPARED TO THE EARLIER POPULATION CENSUS

— 48 —

FIGURE 7. AGE-SEX COMPOSITION BY SINGLE YEAR FOR THE SURVEY COMPARED TO THE 1966 POPULATION CENSUS

— 49 —

The age-sex distribution from the 1974 household survey sample appears to represent closely the national population from which it was drawn (with one exception in the ages 23-24 for males, as noted). The index of dissimilarity between the two distributions is quite low: 4.4 for males and 2.9 for females. The quality of age-reporting too appears to be good. This is seen graphically in Figure 7, where the age-sex structure from the 1974 survey is shown by single years. While there are some irregularities, the Myer's index, which measures the degree of digital preference in age-reporting and can range in value from 0 to 180, is low for both males (5.1) and females (3.5).¹⁰⁷

TABLE 1. AGE AND SEX COMPOSITION OF THE 1974 HOUSEHOLD SURVEY POPULATION COMPARED TO POPULATION CENSUSES OF 1966 AND 1970

Age	Male			Female			Sex Ratio		
	1966 Census	1970 Census	1974 KNFS	1966 Census	1970 Census	1974 KNFS	1966 Census	1970 Census	1974 KNFS

Unknown	—	—	0.1	—	—	—	—	—	—
All ages	100.0	100.0	100.0	100.0	100.0	100.0	101.4	100.8	100.0
Index of dissimilarity ¹⁰⁷ (1970 v. 1974)	4.4			2.9					

¹⁰⁷ Index of dissimilarity = 1/2 the sum of absolute differences between the percentages in each age group for 1970 and 1974

The calculated value represents the number of percentage points that must be shifted between the two distributions to make them equal. Hence, the lower the value the more similar the distributions under comparison.

3.2.3 POPULATION DISTRIBUTION BY SIZE OF COMMUNITY

The communities of Korea are classified by population size as follows:

Area	Population size
Urban:	
Seoul Special City	50,000 or more
Pusan Special City	6,000,000+
Other Large City	2,000,000+
Medium City	500,000 or more
Small City	100,000-499,999
	50,000-99,999
Rural:	
Town	Less than 50,000
Village	20,000-49,999
	Less than 20,000

The 1974 survey was based on a self-weighting probability sample of all the households found in these communities throughout the Republic except for a few special places. Thus, if the sample design was properly implemented, the distribution in these types of communities of the population enumerated in the survey should be similar to the distribution of the total population. A comparison of the 1974 survey and the preliminary counts from the 1975 census shows that they are indeed quite close. The data are summarized in Table 2.

TABLE 2. PERCENTAGE DISTRIBUTION OF POPULATION BY SIZE OF COMMUNITY: 1974 HOUSEHOLD SURVEY COMPARED TO 1975 CENSUS

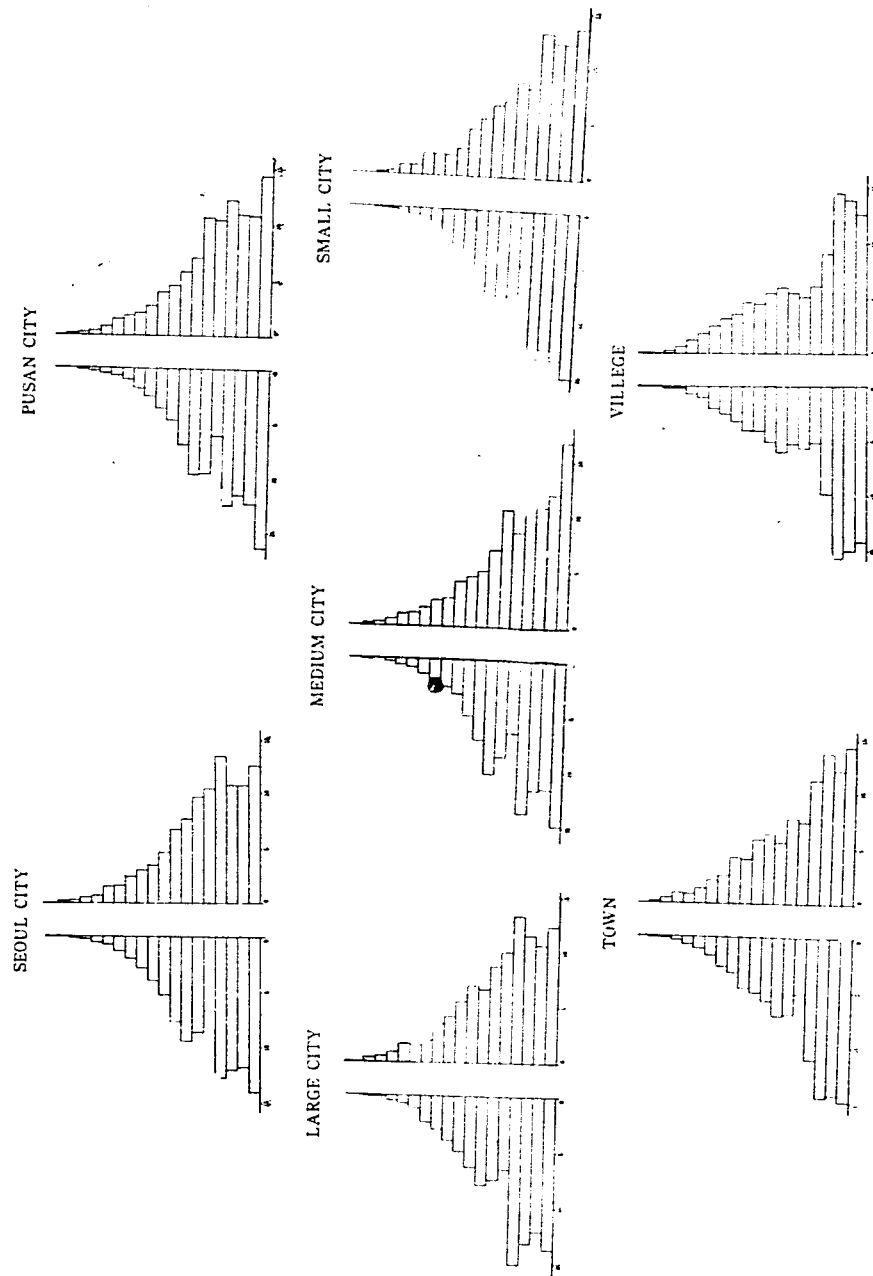

Size of Community	Total		Male		Female	
	1974 Survey	1975 Census	1974 Survey	1975 Census	1974 Survey	1975 Census
	Urban:	48	48	47	48	48
Seoul	20	20	19	20	20	20
Pusan	8	7	8	7	8	7
Large City	7	8	7	8	7	8
Medium City	9	9	9	9	9	9
Small City	4	4	4	4	4	4
Rural:	52	52	53	52	52	52
Town	7	11	7	11	7	11
Village	45	41	46	41	45	41
Total	100%	100%	100%	100%	100%	100%

Source: 1) Preliminary Count of 1975 Population and Housing Census, Bureau of Statistics, Economic Planning Board, Seoul, March, 1976

2) 1974 KNFS, HHS, Table 11.1

If anything, the survey seems to have a slight undercount of the village population and an overcount of the town population, for both males and females. When the population is dichotomized broadly into the urban and the rural sectors, however, the distributions in the survey and the census are identical for all practical purposes: 48 per cent urban and 52 per cent rural.

FIGURE 8. AGE-SEX COMPOSITION BY SIZE OF COMMUNITY

3.2.4 AGE-SEX COMPOSITION BY SIZE OF COMMUNITY

The communities vary considerably in demographic structure (i. e., age-sex composition), depending on their degree of urbanization as measured crudely by size of population. Generally speaking, the larger the size and hence more urban the community, the greater the proportion of population in the productive ages 15-59. The proportionate distribution of the population in each type of community by the conventional three-way groupings—youth, productive ages, and old ages—is shown in Table 3.

TABLE 3. PERCENTAGE DISTRIBUTION OF POPULATION BY THREE MAJOR AGE GROUPS BY SIZE OF COMMUNITY: 1974 HOUSEHOLD SURVEY

Age group	Size of Community							
	Whole Nation	Seoul	Pusan	Large City	Medium City	Small City	Town	Village
Under 15	40	36	38	37	40	40	42	43
15-59	54	60	58	59	56	56	53	49
60 and over	6	4	4	4	4	4	5	8
Total	100%	100%	100%	100%	100%	100%	100%	100%

Source: 1974 KNFS, IHS, table II. 1

Seoul has the largest proportion in the productive ages (60%) and the smallest proportion in the dependent ages (36% under 15 and 4% for 60 and over). The villages by contrast have the smallest proportion in the productive ages (49%) and the largest proportions both in the younger and in the older ages (43% and 8%, respectively). The other community types rank themselves in between these extremes more or less in order by size of community. The comparisons are presented graphically in Figure 8. In every pyramid, the deficit of males in the ages 20-24 shows up clearly. It is also clear that the base which represents recent births is relatively wider for the cities and towns as compared to the villages due obviously to the fact that there is a greater proportion of persons in the productive—and hence, reproductive as well—ages in the cities as compared to the villages. The towns, though they are classified as rural in this report following census definitions, resemble the cities more than the villages in demographic structure. These differences presumably reflect differential employment opportunities and occupational structures in these communities.

3.2.5 POPULATION DISTRIBUTION BY MARITAL STATUS

Since the household survey was used as a screening device to identify the ever-married women in the ages 15-49, a subsample of whom were to be interviewed in the individual survey, it was important that the ever-married be properly enumerated in the household survey. We can test the adequacy of the coverage by comparing the proportion of women ever-married in each age group in the reproductive years as enumerated in the 1974 household survey against the 1970 census. Table 4 shows the comparison.

TABLE 4. PERCENTAGE OF WOMEN EVER-MARRIED IN EACH AGE GROUP IN THE REPRODUCTIVE YEARS: 1974 HOUSEHOLD SURVEY COMPARED TO 1970 CENSUS

Age of women	Percentage ever-married	
	1974 HHS	1970 Census
15-19	3.3	2.9
20-24	44.6	42.6
25-29	90.1	90.3
30-34	96.6	98.5
35-39	99.4	99.6
40-44	99.7	99.9
45-49	99.7	99.8
All ages: 15-49	67.2	68.5

Source: 1) 1970 *Population and Housing Census Report*, Vol. 1, Whole Country, Bureau of Statistics, Economic Planning Board, Seoul, November, 1973.
2) 1974 *KNFS, HHS*, Table II.3

We can safely conclude that the 1974 household survey succeeded in canvassing the ever-married women in the reproductive ages adequately and provided a good frame from which to draw the sample for the individual survey.

3.2.6 POPULATION DISTRIBUTION BY EDUCATIONAL ATTAINMENT

The household survey includes education as a background characteristics. The comparison by sex of the distribution by educational attainment among those age six and over in the 1974 household survey and the 1970 censuses presented in Table 5.

TABLE 5. PERCENTAGE DISTRIBUTION OF POPULATION AGE SIX AND OVER BY EDUCATIONAL ATTAINMENT BY SEX: 1974 HOUSEHOLD SURVEY COMPARED TO 1970 CENSUS

Education	Male		Female	
	1974 HHS	1970 Census	1974 HHS	1970 Census
No schooling	13	14	25	25
Primary	42	49	47	54
Middle	21	18	14	12
High	17	13	10	7
College or higher	7	6	2	2
Total	100%	100%	100%	100%

Source: 1) 1970 *Population and Housing Census Report*, Vol. 1, Whole Country, Bureau of Statistics, Economic Planning Board, Seoul, November, 1973.
2) 1974 *KNFS, HHS*, table II.2.

The proportion with no schooling and the proportion with college education are virtually identical between the two data sources. There is, however, some underrepresentation of those which primary education for both males and females in the 1974 survey as compared to the 1970 census. In the two remaining categories, middle and high school education, there is a slight overrepresentation in the 1974 survey. These differences probably are not large enough to require any adjustment in the kind of analysis presented in this report. The estimate of the non-schooled, an important subgroup, at least is in close agreement between the two distributions.

3.2.7 SUMMARY

1. The Korean household survey, covering 21,253 sample households, enumerated 104,893 persons, 98.6 per cent of whom were usual residents though not necessarily present the night before. 1,431 persons were temporary visitors.
2. The age-sex composition of the household members enumerated in the household survey was similar to that obtained in the 1970 census with the exception in the ages 20-24 for the males. This undercount was due to the exclusion from the sampling frame of the special enumeration districts containing military installations.
3. Age-reporting in the household survey appears to be quite accurate as suggested by the low Myer's index value for both males (5.1) and females (3.5). This index measures the degree of the digital preference in age-reporting, with low scores such as those calculated for this survey indicating little digital preference.
4. The distribution of the surveyed population by size of community basically resembles the preliminary counts from the 1975 census. While there appears to be slight under-representation of village population and an over-representation of the town population in the survey, the distribution by broad urban and rural classification is virtually identical between the two sources of data: 48 per cent urban and 52 per cent rural.
5. A comparison of the age-sex structures of the different sized communities, as obtained in the survey, reveals contrasting patterns between the cities and towns at one end and the villages at the other end. The cities and towns have relatively more persons in the productive ages, 15-59, and fewer persons in the dependent ages, under 15 and 60 and over, as compared to the villages. In comparing the population pyramids, the deficit of males in the ages 20-24 shows up clearly in every type of community and the base representing recent births is relatively wider for the cities and towns than for the villages, reflecting the larger proportion of persons in the productive (and hence, reproductive) ages in the former as compared to the latter.
6. The proportion ever-married by five-year age group covering the reproductive years, 15-49, is very close between the survey and the 1970 census, indicating the adequacy of the 1974 household survey as a sampling frame for the individual survey, which was based on a subsample of the ever-married women 15-49 who were enumerated in the household survey.
7. In both the survey and the 1970 census, no schooling was reported for about 13 per cent of the males and 25 per cent of the females in the ages 6 and over. The proportion of college educated too was nearly identical between the two data sources, but the proportion with primary education was slightly under-represented as the proportion with middle and high school education was slightly over-represented in the survey as compared to the 1970 census.
8. In general, we can conclude that the 1974 household survey sample reflects quite closely the universe from which it was drawn, as the comparison of several characteristics between the surveyed population and the population enumerated in either the 1970 or 1975 census reveals.

3.3 BACKGROUND CHARACTERISTICS OF INDIVIDUAL SURVEY RESPONDENTS

3.3.1 INTRODUCTION

We present in this section a brief description of the background characteristics of women who were subject to the individual survey. The purpose is two-fold. First, it will introduce the reader to the subjects of the inquiry so that it can place the main findings, presented in later sections, in their proper context. Second, by making explicit the associations among the key background variables, a more critical understanding of the data might be facilitated. The relationship between background characteristics and fertility and family planning is often confounded by two demographic variables: wife's age and marital duration. Presented in Tables 5 and 6 are the distributions of the women, respectively, by five-year age group and by marital duration, within each category of the several background characteristics to be examined. In the discussion to follow, some of the background characteristics will be examined in relation to each other as well as in relation to age and marital duration.

3.3.2 AGE AND MARITAL DURATION

The age distribution of the women interviewed in the individual survey is representative of the universe of ever-married women under age 50 from whom they draw, as can be seen in Table 6 where a comparison is made between the 1974 individual survey (KNFS) and the 1970 census.

TABLE 6. PER CENT DISTRIBUTION BY AGE OF EVER-MARRIED WOMEN; 1974 KNFS COMPARED TO 1970 CENSUS

Age	1974 KNFS	1970 census
15-19	1	1
20-24	10	10
25-29	22	20
30-34	20	22
35-39	19	19
40-44	15	15
45-49	12	13
All ages	100%	100%
Index of dissimilarity*		3.0

*See note under Table 1 for meaning of this index.

Source: 1) 1970 *Population and Housing Census Report*, Vol. 1, Whole Country, Bureau of Statistics, Economic Planning Board, Seoul, November, 1973
2) 1974 KNFS, Table 1.1.1

The paucity of respondents in the ages below 20 is of course a reflection of the relatively high ages at which women in Korea marry today. (See Section 3.4 below.) The median age is about 34.

The distribution by marital duration is presented in Table 7.

TABLE 7. PER CENT DISTRIBUTION OF 1974 KNFS SAMPLES BY MARITAL DURATION

Marital duration	Per cent
Less than 5 years	22
5-9 years	19
10-14 years	15
15-19 years	15
20-24 years	12
25-29 years	10
30 years or more	7
All durations	100%

Source: 1974 KNFS, Table 1.2.1

The relatively small number of women found in the last category reflects the fact that few women subject to this survey were married before age 15. (See Section 3.4 below.) The median duration of marriage for these women is about 13 years.

The importance of these two demographic variables is that they are related to several of the background characteristics as well as to fertility and family planning behaviour—the main focus of the present survey—and therefore must be taken into account in any analysis involving the background characteristics in relation to the latter. Often the observed bivariate relationship between a background variable and fertility or family planning behaviour hides an age or marital duration effect.

3.3.3 EDUCATION AND LITERACY

Educational level is grouped in five categories: no education, primary school, middle school, high school, and college. As shown in Tables 8 and 9, 21 per cent report no schooling, 50 per cent report only primary school education, and 29 per cent middle school or more. College education is reported by only 3 per cent. It is clear from these tables that educational attainment is closely related to both age and marital duration. Those who report no schooling are definitely concentrated in the older ages and the longer marital durations, while those with middle school education or more are concentrated in the younger ages and the shorter marital durations. These trends result from the recency of improvement in educational opportunities in Korea for women, in particular.

That the better educated tend to be younger and more recently married must be taken into account when education is examined in relation to fertility and family planning. The age and marital-duration effects are further confounded by the fact that the better educated tend to marry late. (See Section 3.4.3 below.) We note that the college-educated are grossly underrepresented in the youngest category due obviously to the fact that they generally tend to marry late and most of them would not be eligible for this survey. This truncation effect does not appear when their distribution by marital duration is considered.

Literacy is not used as a variable in this report because of its close relationship with education. Eighty-two per cent of the respondents are classified as literate. This percentage is as high as 97 per cent for those under 25 years of age, reflecting again the diffusion of education in recent times.

TABLE 8. PERCENTAGE DISTRIBUTION OF EVER-MARRIED WOMEN BY AGE, WITHIN CATEGORIES OF SELECTED BACKGROUND VARIABLES; INDIVIDUAL SURVEY

Source: 1974 KNFS, Table 1.5.2

3.3.4 TYPE OF PLACE OF RESIDENCE

The respondent's current place of residence is classified into three categories: "city", defined to include the 35 cities of Korea with population 50,000 or over; "town", defined as rural places with population between 20,000 and 50,000; and "village", defined as places with population under 20,000. Fifty-two per cent of the respondents were from cities, 8 per cent from towns, and 40 per cent from villages.

Tables 8 and 9 show that the city residents are slightly younger and more recently married as compared to the general population of ever-married women, while the village residents show the reverse trends. The town residents, on the other hand, show an age composition and marital duration distribution similar to the general population of ever-married women. As in the case of education, both age and marital-duration effects must be taken into account when type of place of residence is examined in relation to fertility and family planning.

There are also large variations in the respondent's level of educational attainment by type of place of residence. From Table 6.1.1 we can calculate that 44 per cent of city residents had more than primary level education, compared to 20 per cent of town residents and only 11 per cent of village residents. Thus, level of education too should be an important factor potentially in accounting for some of the differences in fertility and family planning behaviour by type of place of residence.

Data from Table 6.2.5, where the type of place of residence in childhood is shown by the type of current residence, reveal that most of the current city residents are migrants from other types of places. For example, only 27 per cent of the current city residents spent their childhood in cities. By contrast, 88 per cent of the current village residents spent their childhood also in villages.

3.3.5 RELIGION

Religion has not been an important factor in previous fertility surveys in Korea. The majority of respondents (61%) professed no religion. Twenty-four per cent reported being Buddhists, 10 per cent Protestants, 4 per cent Catholics, and 1 per cent "other" religions (such as, confucianism).

There is very little variation between the religious groups in age composition and marital-duration distribution, as can be seen in Tables 8 and 9. There is, however, some variation by type of place of residence and education, the latter substantially more than the former. Respondents with no religion are slightly more frequent in villages (69%) than in towns and cities (56%), according to Table 6.2.1. Protestants and Catholics have had better education generally than Buddhists and those who profess no religion. Forty-two per cent of the Christians as compared to 23 per cent of the Buddhists and 25 per cent of those with no religion have had more than primary level education. (From Table 6.1.2.) These relationships suggest that the effect of religion, if any, on fertility and family planning is likely to reflect to some extent the effects of type of place of residence and education. At least, such possibilities must be taken into account in analysis.

3.3.6 HUSBAND'S OCCUPATION

Husband's occupation tells us something about the status and life style of the couple. Although information on husband's employment status, education, and childhood place of residence

too was obtained, attention is restricted to his occupation in this report. The seven groups of occupations in Tables 8 and 9 are based on the International Classification of Occupations and the slight modifications recommended by V.R.S. The largest group in the sample consisted of agricultural workers (35%), followed by skilled or semi-skilled manual workers (25%), sales and service workers (15%), professional and managerial workers (9%), clerical workers (7%), unskilled manual workers (7%), and those who never worked (2%).

Differences in the composition of these groups by wife's age and marital duration are slight, except for the agricultural workers whose wives tend to be somewhat older and married longer than the others. (See Tables 8 and 9.)

As would be expected, husband's occupation is closely associated with respondent's type of place of current residence and her educational background. For example, from Table 6.2.2, we can see that 70 per cent of the husbands of village residents are classified as agricultural workers, compared to 40 per cent of town residents and 6 per cent of city residents. Wives of professional and managerial workers are the most highly educated group: 72 per cent had formal education beyond the primary level. (From Table 6.1.3) The percentages of wives educated beyond the primary level for other groups were: 61 per cent for clerical workers, 43 per cent for wives whose husbands had never worked, 36 per cent for sales and service workers, 33 per cent for skilled and semi-skilled manual workers, 10 per cent for unskilled manual workers, and 6 per cent for agricultural workers.

3.3.7 PATTERN OF WORK

Wife's pattern of work is a composite variable derived from details of her work history at three points in time: before marriage, after marriage, and at interview. Fifty per cent of the respondents had worked before marriage, 60 per cent after marriage, and 48 per cent were working at interview. Twenty-two per cent had never worked either before or after marriage. As can be seen in Tables 8 and 9, the pattern of work variable comprises of mutually exclusive categories that result from the combination of work experience at these three points in time. The first two categories are made up of those currently working and the next three categories, of those not currently working. Further subdivisions within these broad groupings are based on whether the respondent worked before or after marriage. The ordering of these categories assumes that commitment to extra-familial activities is stronger the greater the work involvement measured at these three points in time (though further refinement is needed, with data available from the present survey, to distinguish between those who worked at home on a farm or family business or away from home, among other things).

As already noted, nearly half the respondents (48%) were currently working and of these 25 per cent had worked before marriage also and 23 per cent after marriage only. Seven per cent had worked both before and after marriage and another 5 per cent only after marriage, though not working at the time of the interview. Eighteen per cent had worked before marriage only.

The relationship between pattern of work and age or marital duration presents a complicated picture. There is suggestion that possibly pattern of work is a function of the stages in a woman's life cycle. In Tables 8 and 9, for example, those who worked only before marriage tend to be young (81% are under 35) or recently married (77% have been married less than 10 years), while those who worked after marriage only, whether currently working or not, tend to be older (66-67% are 35 and over) or married longer (47% have been married 20 years or

TABLE 10. PERCENTAGE OF WIVES CURRENTLY WORKING BY HUSBAND'S OCCUPATION

Unskilled manual	39
Never worked	27
Total	49

Source: 1974 KNFS, Table 6.3.2

more). A much more refined analysis than offered here is needed to fully understand these relationships.

There is a strong relationship between the respondent's pattern of work and her husband's occupation. In particular, the proportion of women currently working varies greatly with the nature of husband's occupation, as shown above in Table 10.

More than three-fourths of the women whose husbands are agricultural workers are currently working—presumably also as agricultural workers. Sales and service workers too have relatively high proportion of currently working wives.

The relationship between pattern of work and education appears to be confounded by age and type of work. For example, currently working women are not better educated than those who are not currently working: 71 per cent of the former as compared to 90 per cent of the latter had education beyond the primary level. Of those not currently working, the ones who worked before marriage tend to be somewhat better educated (90% had more than primary education) than the ones who did not work before marriage (88% had more than primary education). These relationships must be interpreted with caution, given the earlier observations that suggest some complicated relationship between pattern of work and age and also type of work (for example, a fair proportion of those currently working are likely to be in agriculture as suggested by the fact that 48 per cent are village residents).

The respondent's most recent occupation, if she had ever worked, was also asked in the interview, although this variable is used for analysis only briefly in this report (See, for example, Table 35). As expected, this variable is closely associated with education, as shown below in Table 11.

TABLE 11. PERCENTAGE OF WOMEN HAVING MORE THAN PRIMARY SCHOOL EDUCATION BY THEIR MOST RECENT OCCUPATION

3.3.8 NUMBER OF MODERN OBJECTS

The WFS recommends that the household schedule include questions on household availability of certain modern objects. The Korean survey included a list of nine objects: clock or watch, bicycle, radio, sewing machine, television set, phonograph, telephone, refrigerator, and piano or organ. The purpose of these questions is to derive an index of modernity, which is assumed to be linked to the modernity values of any women in the household selected for the individual interview. This index will be used in further analysis of the data beyond the scope of this report. The tables presented at the end of this chapter do include a simple index, the number of modern objects owned, as one of the background characteristics.

The distribution of the sample according to number of modern objects owned is shown below in Table 12.

TABLE 12. PERCENT DISTRIBUTION OF EVER-MARRIED WOMEN BY NUMBER OF MODERN OBJECTS OWNED

Number of modern objects	Per cent distribution of ever-married women
None	4
One	12
Two	23
Three	27
Four	18
Five	9
Six or more	8
Total	100%

Source: 1974 KNFS, Table 6.2.3

Number of modern objects owned is strongly related to other background variables, including education, type of place of residence, and husband's occupation. (From Table 6.1.4, 6.2.3, and 6.3.1). Ownership of five or more modern objects is prevalent among the better educated, the city residents, and associated occupations such as professional, managerial, and clerical work.

3.3.9 SUMMARY

1. The individual survey, based on 5,420 ever-married women in the ages 15~49 a subsample of the ever-married women in these ages enumerated in the household survey, provides the basis for much of the analysis presented in this report, dealing with fertility and family planning as related to several demographic and socioeconomic background variables.
2. The two most important demographic variables that must be controlled when examining the relationship of socioeconomic background characteristics to fertility or family planning are: age and marital duration. These two variables are closely related to fertility and family planning and to some of the background characteristics in distinctive ways and therefore must be taken into account in any analysis involving fertility or family planning, on the one hand, and socioeconomic characteristics, on the other. The background characteristics too are interrelated in such a way as to sometimes confound the analysis of the relationship between a given characteristic and fertility or family planning. In this section, an attempt was made to show (1) the age and marital duration composition of the women classified by several background characteristics to be examined in this report and (2) the relationship of some of the background characteristics to each other.

3. The age distribution of the 1974 individual survey sample is virtually identical with the age distribution of ever-married women 15-49 in the 1970 census, indicating that the former provides an adequate representation of the universe from which it was drawn.

4. To give a profile of the respondents, we can summarize some of their background characteristics as follows:

- a. Median age: 34 years
- b. Median duration of marriage: 13 years
- c. Current residence: 52 per cent resided in cities, 8 per cent in towns, and 40 per cent in villages.
- d. Education: 21 per cent reported no schooling but 79 per cent had more than primary level education, with 3 per cent reporting college level education.
- e. Religion: 61 per cent reported no religious preference, 21 per cent are Buddhists, 10 per cent Protestant, 4 per cent Catholics, and 1 per cent "others" such as Confucianists.
- f. Husband's occupation: 35 per cent were in agriculture, 32 per cent in white-collar jobs (professional and managerial, 9%; clerical, 7%; and sales and services, 15%), 32 per cent in nonagricultural manual jobs (skilled, 25% and unskilled, 7%), and 2 per cent had never worked.
- g. Wife's work experience: 48 per cent were working at the time of interview, 12 per cent had worked since marriage though not now working, 18 per cent had worked only before marriage, and 22 per cent had never worked.
- h. Number of modern objects owned: Only 4 per cent of the respondent's household owned none of the objects listed in the survey as modern objects; 35 per cent owned 1 to 2 objects; 45 per cent 3 to 4; and 16 per cent 5 or more.

5. Educational attainment is closely related to both age and marital duration. The non-schooled are concentrated in the older ages and the older marriage cohorts. The better educated by contrast are younger in age and tend to be in the more recent marriage cohorts as well, due both to the tendency of improvement of educational opportunities in Korea for women, in particular and to the tendency of the better educated to marry late. The college-educated in particular are grossly underrepresented in the youngest age category due to the fact that they generally tend to marry late and most of them would not be eligible for this survey.

6. Type of place of residence is also closely related to both age and marital duration. The city residents tend to be younger and more recently married as compared to the village residents, with the town residents, in-between. Educational composition varies also by type of place of residence. The city residents are generally better educated than the town residents, who in turn are better educated than the village residents.

7. Religious groups do not show much variation in age or marital duration composition. They do, however, vary some in educational composition and place of residence. The Christians tend to be better educated than either the Buddhists or those who profess no religion, who in turn are slightly more frequent in villages than in cities and towns.

8. Husband's occupation is related to wife's age and marital duration only slightly, except for the agricultural workers whose wives tend to be somewhat older and married longer than the others.

It is related in significant ways to type of place of residence and wife's education, as might be expected. The agricultural workers are obviously more frequent in villages and the wife's educational attainment is higher for the professional, managerial, and clerical workers as

compared to the others. The wives of unskilled manual workers and agricultural workers are the least educated.

9. Wife's pattern of work is related to age and marital duration in ways difficult to unravel at this stage of analysis. There is, however, a discernible tendency for those who worked only before marriage to be still relatively young and only recently married. Those who worked after marriage only by contrast tend to be older and married longer. It appears that pattern of work is related to the stages in the women's life cycle. Wife's pattern of work is related to husband's occupation. The proportion of women currently working is highest for those whose husbands are in agriculture, followed by those in sales and services.

The relationship of pattern of work to education is confounded by age composition. There is some suggestion, however, that those who are not currently working but worked before marriage tend to be somewhat better educated than those who did not work before marriage. Educational attainment is also closely related to the type of work the woman has been engaged in most recently: professional and clerical workers are the best educated and the agricultural workers, the least.

3.4 NUPTIALITY AND EXPOSURE TO CHILDBEARING

3.4.1 INTRODUCTION

For women in most societies, exposure to childbearing commences at the time of entry into a more or less stable sexual union. In Korea, this occurs usually at marriage defined in formal terms. Although reliable data on illegitimate births are not easily obtained, it appears safe to assume that in Korea childbearing takes place largely within marriage, given that strong social sanctions exist to discourage widespread illegitimacy. In any case, the individual survey in Korea was confined to ever-married women, applying a formal definition of marriage. Timing of first marriage, therefore, becomes an important factor in defining the period of exposure to childbearing.

Following marriage, the persistence and intensity of exposure to childbearing depends on many factors, including marriage dissolution and remarriage, temporary separation of spouses, coital frequency and patterns of sexual abstinence, and sterility. Some of these factors (other than coital frequency and patterns of sexual abstinence) were measured in the present survey, though the discussion of their full implications must await further processing of the data. In this report, marriage dissolution, remarriage, and sterility along with timing of first marriage, will be considered in a preliminary way as a basis for assessing their possible contribution to the explanation of the observed patterns of Korean fertility.

3.4.2 TRENDS IN PROPORTION SINGLE BY AGE GROUP

The household survey data permit the examination of the distribution of males and females by marital status. A time perspective is provided when the 1974 survey results are compared with census results from previous years. Table 13 summarizes the data on proportion single by age group for different time periods.

33

Looking at the 1974 survey results, we see that marriage for males is rare in the ages before 25 and for females, in the ages before 20. On the other hand, there is nearly universal marriage after age 35 for males and after age 30 for females. The time series comparison reveals that these trends were already established by 1966. The contrast of these trends with 1935 and 1955 is remarkable. In these years, marriage was much earlier for both sexes. For example, in 1935, nearly one-quarter of the males and two-thirds of the females were already married before age 20 and all but 4 per cent were married in the ages 20-24. By 1955, there is evidence of considerable delay in marriage for both sexes, though still earlier than for 1966 and thereafter.

3.4.3 TRENDS IN AGE AT FIRST MARRIAGE

The singulate mean age at marriage calculated from data on proportion never married at each age obtained in the 1974 household survey can be compared with similar means calculated from censuses in previous years.¹¹⁾ The results, summarized in Table 14., confirm the observations made above in Section 3.4.2. Mean age at marriage for males has risen steadily from 21.1 in

11) The singulate mean age at marriage is an indirect estimate of the mean age at first marriage. It is based on data on marital status by age. More specifically, it represents an estimate of the mean number of years lived by a cohort of males or females before their first marriage. For a description of the method, see Henry S. Shryock, Jacob S. Siegel, and Associates, *The Methods and Materials of Demography*, Volume 1, Washington, D.C.: U.S. Bureau of the Census, 1971, p. 295. In interpreting the statistics, it should be cautioned that the mean summarizes the experience of all the persons enumerated in the different ages at a given point in time and does not refer to any cohort in the real sense of the word.

1935 to 23.7 by 1955 and to 27.1 in 1970 and 27.2 in 1974. For females, it has risen from 17.1 in 1935 to 22.8 by 1955 and to 23.3 in 1970 and 23.2 in 1974. For both sexes, there is hint of stabilization since 1970. Interestingly, the age difference at marriage between males and females has remained more or less constant over these years at about 4 years on the average.

Mean age at marriage can be calculated for each age cohort for women interviewed in the individual survey, although generalizations with regard to trends must be made with caution because of the problem of gross censoring of data inherent in a sample confined to ever-married women. Table 15 summarizes the data. If attention is focused on the age groups above 25, the rise in age at marriage noted earlier is demonstrated here also. Mean age at marriage for women currently aged 45-49 was 17.1, as compared to 21.7 for women currently aged 25-29. The age groups under 25 suffer from censoring effect as those already married are selected by their early marriage and are not fully representative of those in these ages. The bias is reflected in the low calculated mean for these age groups: 17.1 and 20.0, respectively, for ages 15-19 and 20-24. The last column in Table 15 gives the proportion ever-married by age group, based on the household survey, and can be used as a reference in assessing the meaningfulness of the calculated mean age at marriage in each age group.

3.4.4 DIFFERENTIALS IN AGE AT FIRST MARRIAGE

Differentials in women's age at first marriage can be examined by two variables using household data: size of community and education. The singulate mean age at marriage for women by these background variables can be calculated from data on proportion single by age group as presented in Table 16. Mean age at marriage for women is higher the larger and more urban the community. Women in Seoul, for example, married on the average at 24.1 as compared to women in villages who married on the average at 22.8. The women in other types of communities generally rank themselves between these two extremes more or less in order of community size, though the differences are not large.

TABLE 14. SINGULATE MEAN AGE AT MARRIAGE FOR MALES AND FEMALES: 1974 HOUSEHOLD SURVEY COMPARED TO CENSUS OF 1935, 1955, 1960, 1966, AND 1970

Year	Male	Female	Difference in Years
1935 Census ¹⁾	21.1	17.1	4.0

TABLE 15. MEAN AGE AT FIRST MARRIAGE BY CURRENT AGE: ALL EVER-MARRIED WOMEN (1974 INDIVIDUAL SURVEY); AND PERCENTAGE EVER-MARRIED (1974 HOUSEHOLD SURVEY)

Current age	Mean age at first marriage (1974 KNFS)	Per cent ever married (1974 IHS)
15-19	17.1	3.3
20-24	20.0	44.6
25-29	21.7	90.1
30-34	21.3	98.6
35-39	20.0	99.4
40-44	18.4	99.7
45-49	17.1	99.7
All ages	20.0	67.2

Source: 1974 KNFS, IHS, Table II.3

Educational differentials are much more marked. The college educated and those with high school education, for example, married on the average at 25.6 and 25.0, respectively, as compared to those without any schooling who married on the average at 21.3. The others are intermediate to these: those with primary education marrying at 21.9 and those with middle school education at 22.8.

TABLE 16. PERCENTAGE OF WOMEN SINGLE (NEVER MARRIED); BY CURRENT AGE AND SINGULATE MEAN AGE AT MARRIAGE, BY CURRENT RESIDENCE AND EDUCATION; 1974 HOUSEHOLD SURVEY

Background characteristics	Age of women								Singulate mean age at marriage

Source: 1974 KNFS, IHS, Table II.3

The individual survey data permit the exploration of differentials in mean age at marriage by several other background characteristics, though interpretation must be tempered somewhat by the censoring effect noted earlier. In order to remove some of the censoring effect, mean age at marriage is calculated for only those who were age 25 or older at interview and who had married before age 25 (about 80 per cent of the sample). Such a restriction serves to exclude the youngest cohorts who are selected by their early marriage and the late marriages among the cohorts above age 25, both of which suffer from gross censoring effects. The analysis of

differentials in mean age at marriage, based on the individual survey, must therefore exclude observations on the most recent trends and also use data that necessarily underestimate the mean age at marriage for each cohort, especially among those with background characteristics associated with relatively late marriage. Even with these restrictions, the findings are nevertheless still suggestive of interesting trends. Table 17 summarizes the data. Education has the strongest association with age at marriage. In every age group, the college-educated have the highest average age at marriage and those with no schooling, the lowest. Overall, the mean age at marriage among the college-educated was 21.9, as compared to 17.5 for those with no schooling. The actual differentials are likely to be even greater as witness in Table 18 the fact that the proportion married after age 25 and therefore excluded from the analysis is larger the higher the educational level.

TABLE 17. MEAN AGE AT FIRST MARRIAGE OF THOSE WOMEN WHO WERE MARRIED BEFORE AGE 25 BY BACKGROUND CHARACTERISTICS AND CURRENT AGE

Background characteristics	Current age					
	All ages	25-29	30-34	35-39	40-44	45-49
All women	19.4	21.1	20.5	19.5	18.1	16.9
Level of education:						
No schooling	17.5	19.5	19.2	18.5	17.1	16.2
Primary school	19.5	20.7	20.4	19.6	18.3	17.2
Middle school	21.2	21.8	21.3	20.6	(19.1)	*

Unskilled manual	19.1	20.8	19.7	19.4	17.7	(16.4)

In this and all subsequent tables in the text, () refers to figures based on less than 50 cases and an asterisk (*), to figures based on less than 20 cases.

Source: 1974 KNFS, Table I.1.3

Those who spent their childhood in cities tend to marry slightly later than those who spent their childhood in towns or villages, though the differences are diminished among the more recent

cohorts. Differences in mean age at marriage by religious affiliation are small. If anything, the Buddhists and those with no religion tend to marry at slightly younger ages than the Protestants or Catholics, though again the differences are substantially reduced among the most recent cohort. Some of the religious differences probably reflect the urban-rural composition of the different religious groups. As we noted earlier, Buddhists and those with no religion tend to be more rural in composition than any of the Christians.

College	46
Total	9

Source: 1974 KNFS, Table 1.1.3, 6.1.1

A higher mean age at marriage is found generally among those who worked before marriage. But if the work was family-related, the mean age at marriage is as low as for those who did not work. These patterns are found in every age group. It is likely that level of education and place of residence influence these patterns.

Wives married professional and managerial workers tend to have married later than the others. Wives of farmers on the average married earliest. These differentials are evident in every age group.

It is worth noting in Table 17 that mean age at marriage has risen from the oldest to the youngest cohort in every category of the several background characteristics examined, suggesting that the observed secular trend of rising age at marriage is a pervasive phenomenon affecting every sector of Korean society.

3.4.5 MARITAL STABILITY

Any marriage is subject to dissolution sooner or later either by one of the spouses dying before the other or by divorce or separation due to marital discord. Fertility certainly would be affected to the extent that there is disruption in exposure to risk of childbearing when marriage is dissolved and remarriage, if any, does not follow immediately. How soon and how often marital dissolution and remarriage occur are known to vary by time and place, not only between countries but also within any given country. Korea is no exception.

Table 19 shows the percentage of ever-married women who were widowed, divorced, or separated in 1974 based on the household survey: 5.5 per cent were widowed, 1.0 per cent divorced, and 1.8 per cent separated. Over the years, widowhood has probably decreased, due to the improvement in adult mortality, but unfortunately comparable figures are not easily available from previous years to confirm this.

For the ever-married women subject to the individual survey, we can examine both the status of the first marriage and the current marital status by marital cohort. Table 20 summarizes the data.

TABLE 19. PER CENT DISTRIBUTION OF EVER-MARRIED WOMEN 15-49 BY CURRENT MARITAL STATUS: 1974 HOUSEHOLD SURVEY

Current marital status	Per cent
Currently married	91.7
Widowed	5.5
Divorced	1.0
Separated	1.8

Source: 1974 KNFS, Table 1.2.1

About 10 per cent of all first marriages of women interviewed had been dissolved 7.2 per cent by death of the husband and 3.2 per cent by divorce or separation. (These data underestimate the true rate of marital dissolution by death of a spouse since only those first marriages in which the wife has survived are included in the sample.) The proportion experiencing dissolution of their first marriages is higher the older the marital cohort. This presumably is a function both of elapsed time since first marriage and of cohort differences. For example, the higher rate of widowhood for the older cohort can be explained by the greater risk of mortality with advance in age and the occurrence of the Korean War some 25 years ago. Note that the rate of widowhood is as high as 23.4 per cent and 26.2 per cent for the two oldest cohorts. The present tabulations do not permit us to differentiate the effect of aging from the differential circumstances affecting the cohorts.

About 4 per cent of the women have been married more than once. As expected, the proportion who have been married more than once is higher the older the cohort. The effect of remarriage is to raise the proportion who are currently married as of the date of interview (93.2%) to a level somewhat above the proportion whose first marriages remained intact (89.6%). Altogether 40 per cent of those whose first marriages were dissolved had remarried by the time of the interview. (See the "total" column in Table 1.3.2.A, for example.)

Some differentials in the stability of first marriages are shown in Table 21. Ostensibly, those with some schooling and those residing in cities have fared better (i. e., more first marriages have remained intact) than those with no schooling and those residing in towns or villages. There are also no apparent differences by religious affiliation. These apparent differentials, however, hide differences in composition by marital duration by background characteristics. If we focus our attention on those who were married at least 25 years ago, we find that the rate of first marriage dissolution tends to be higher for the better educated, the city residents, the Protestants, and the Catholics, suggesting that rates standardized on marital duration are likely to show a picture different from what the total column shows in Table 15.

This is partially confirmed in a comparison of the rates for places of current residence when they are standardized on the marital-duration distribution of the total sample. The standardized rates are: 11.2 per cent for city residents, 11.8 per cent for town residents, and 9.4 per cent for village residents. In short, the city residents have experienced a high rate of first marriage dissolution as the town residents and somewhat higher rate than the village residents, reversing the pattern based on unstandardized rates shown in the first column of Table 21. Similar reversals could be expected for education and religious affiliation, though standardization is not attempted with these background characteristics due to the small cell frequencies that obtain when they are cross-tabulated by marital duration.

TABLE 21. PERCENTAGE OF ALL EVER-MARRIED WOMEN WHOSE FIRST MARRIAGE WAS DISSOLVED, BY BACKGROUND CHARACTERISTICS BY YEARS SINCE FIRST MARRIAGE

	Years since first marriage							
	All duration	Less than 5	5-9	10-14	15-19	20-24	25-29	30+

Source: 1974 KNSF, Table 1.2.2

While several tables were prepared on the rate of remarriage after the dissolution of the first marriage by background characteristics (Tables 1.3.2A-C), the data are difficult to interpret since there is no control on elapsed time since first marriage dissolution. The apparent result that show lower rates of remarriage for the better educated, city residents, and Catholics must be viewed with caution until such a control is introduced in further analysis of the data at a later time.

3.4.6 EXPOSURE STATUS

The composite variable "exposure status" is defined by five possible categories, based on the WFS guideline. This variable is used to establish a woman's current degree of exposure to the risk of conception. At one extreme is a woman who is currently pregnant; she has zero

TABLE 22. PER CENT DISTRIBUTION OF ALL EVER-MARRIED WOMEN ACCORDING TO EXPOSURE STATUS, BY DEMOGRAPHIC AND SOCIAL CHARACTERISTICS

Characteristics	Exposure status					Total
	Currently pregnant	Widowed divorced separated	Sterilization for contraception	Other impairment	Reported fecund	
All women	10	7	5	12	66	100
Current age:						
15-24	28	1	0	0	71	100
25-34	14	2	4	2	78	100

Village	10	7	3	14	67	100

Source: 1974 KNFS, Tables 1.6.1

probability of conceiving in the next month. A woman who is not pregnant, is married and living with her husband, and reports that she is able to have children, defines the other extreme.

Exposure status is a useful tool, especially as the concepts of infecundity and exposure will recur in later sections on current contraceptive use and family size intentions.

Table 22 summarizes the distribution according to exposure status by demographic "control variables"—such as age, marriage duration, and parity. About ten per cent of the women report a current pregnancy. Contraceptive sterilization is not particularly widespread, amounting to 5 per cent of the entire sample. Two-thirds of all ever-married women are exposed (i. e., reported fecund), 7 per cent are currently not married, and the remaining 12 per cent report impaired fecundity. The proportion exposed is highest in the ages 25-34 (78%) or marital duration of 10-14 years (82%), declines slowly up to around age 45 or up to 30 years of marriage and then drops precipitously after that.

Nearly 40 per cent of all women with no children to date are currently pregnant. These presumably are predominantly recently married women who are having their first children. Eleven per cent do report some kind of fecundity impairment, however, suggesting that a significant minority are involuntarily childless. Fecundity impairment increases considerably after parity 3 to 14 per cent for parity 4 and 24 per cent for parity 5 or more.

Differentials in exposure status by background characteristics shown in the bottom panels of Table 22 must be interpreted with caution as they are presented without any age control. (See Tables 1.6.3A-B for a detailed age-controlled display of the data.) Sterilization for contraceptive

purposes is most frequent among the college-educated (14%) and the city residents (6%). This is true especially in the ages 35-44. The low rate (4%) of current pregnancy among those without any schooling is strictly a function of the age composition of that group. The higher rate (13%) of marital dissolution and the greater incidence of fecundity impairment (26%) among them too are accounted for primarily though not completely by age composition. The consequence, of course, is that the proportion exposed (53%) is lowest among those without any schooling.

3.4.7 SUMMARY

1. This section examined the trends and differentials in the timing of first marriage and marital stability as a basis for understanding the trends and differentials in fertility, examined in the next section, since exposure to childbearing is a function of these factors.
2. The household survey data show that marriage is rare in the ages before 25 for males and before 20 for females but is nearly universal by 35 for males and by 30 for females. These trends appear to have been established already by 1966.
3. The singulate mean ages at marriage by sex calculated from the household survey data on proportion never married at each age are 27.2 for males and 23.2 for females. These figures represent rising trends in age at marriage for both sexes over the years, though appear to have stabilized since about 1970.

38

4. Mean ages at marriage calculated for each age cohort for women interviewed in the individual survey also show rising trends, though interpretation must be tempered somewhat due to the censoring effect associated with data confined to ever-married women. The mean age at marriage for women currently aged 45-49 was 17.1 as compared to 21.7 for women currently aged 25-29. The means for those under 25 (17.1 for age group 15-19 and 20.0 for age group 20-24) suffer from truncation due to the fact that those included in the survey are selected by their early marriage and do not represent the full range of experience, yet to come of the age cohorts.

5. Differentials in age at first marriage could be examined for size of community and education by use of the household survey data, which permit the calculation of the singulate mean age at marriage by these background characteristics.

The singulate mean age at marriage for women is higher the larger and more urban the community. For example, the mean was 24.1 for women residing in Seoul as compared to 22.8 for those in villages. The differentials by education are even more marked. For example, the singulate mean age at marriage was 25.6 for college-educated women as compared to 21.3 for those with no schooling.

6. Differentials in age at marriage could be examined for several other background characteristics by use of the individual survey data, though censoring effect inherent in the data based on ever-married women must be taken into account. The comparison was confined, therefore, to those who were 25 or older and had married before 25.

- a. Education has the strongest association with age at marriage. The results are consistent with findings based on the household survey data. The better educated married at later ages than the less educated in every age cohort.

- b. Those who spent their childhood in cities married slightly later than those who spent their childhood in towns or villages. Differences are diminished among the recent cohorts, however.

- c. A higher mean age at marriage is found among those who worked before marriage. If, however, the work was family-oriented, the mean age at marriage was as low as those who did not work.

- d. The women who married men in professional or managerial positions married at later ages than the others, with the agricultural wives marrying earliest. These differences are evident in every age group.

7. Mean age at marriage, calculated from the individual survey (restricted, as we noted, to those 25 and over and married before 25) shows a rising trend from the oldest to the youngest cohort in every category of background characteristics examined, indicating the pervasiveness of the rise in age at marriage throughout the different sectors of Korean society.

8. The household survey data show that 92 per cent of the ever-married women in the ages 15-49 were currently married, 6 per cent were widowed, 1 per cent divorced, and 2 per cent separated.

9. From the individual survey, the rate of dissolution by cause of the first marriages of the women studied could be obtained: 7 per cent were dissolved by death of the husband, and 3 per cent by divorce or separation.

The proportion experiencing dissolution of their first marriages was higher the older marital cohort presumably due to both greater risk associated with longer period of exposure since first marriage and to cohort differences. These effects cannot be differentiated from the tabulations so far available.

10. Altogether 40 per cent of those whose first marriage were dissolved remarried by the time of the interview, with the result that the proportion married at interview (95.2%) was higher than the proportion whose first marriage remained intact (89.6%). About 4 per cent of the surveyed women had married more than once, the proportion of remarriages rising with length of elapsed time since first marriage.

11. Differentials in the stability of first marriage are difficult to discern without controlling for marital duration. The rates of first marriage dissolution standardized on marital duration composition are lower for the city (9.4%) than the town (11.8%) and village residents (11.2%). Standardized rates must be calculated for other background characteristics (e.g., education and religion) too in order to demonstrate any differentials by these characteristics.

12. No conclusions are possible concerning differentials in rate of remarriage by background characteristics without controlling for elapsed time since first marriage dissolution. Analysis of this topic must await cross-tabulations that take this factor into account.

13. The surveyed women's current degree of exposure to risk of conception is defined by a composite variable referred to as "exposure status" in this study. By the definition employed, two-thirds of all ever-married women 15-49 are "exposed" in the sense that they are currently married, not pregnant, and free of fecundity impairments. The proportion "exposed", or fecund, is highest in the ages 25-34 or marital duration of 10-14 years, declines slowly up to age 45 or 30 years of marriage, and then drops precipitously after that.

14. About 10 per cent of all surveyed women reported being currently pregnant. The proportion reporting current pregnancy is highest (39%) among those with no children to date. These women are no doubt recently married and having their first children.

15. Fecundity impairment accounts for 11 per cent of those who were childless. Fecundity impairment generally increases with age, marital duration, and parity. The proportion reporting some kind of impairment is quite high after age 45 (55%), 25 years of marriage (35-60%), and parity 5 (24%).

16. Differentials in exposure status by background characteristics are confounded by age composition. For example, the low rate of current pregnancy or the high rate of marital dissolution and fecundity impairments among the non-schooled is a function of their older age composition.

3.5 FERTILITY

3.5.1 INTRODUCTION

The measurement of fertility may be approached in two ways: the cohort, or cumulative approach, and the period, or cross-sectional approach. Cohort measurements express the cumulative birth performance of groups or cohorts of women as they progress through their childbearing years. Two types of cohorts, birth and marriage, have been used in this report. The period, or cross-sectional, approach to fertility measurement is concerned with the number of births which occur to a defined population during a specified calendar year or other historical time period. The crude birth rate, age-specific fertility rates, and general fertility rates are familiar examples. They are often referred to as measurements of "current fertility."

It will be recalled that the household survey in Korea was based on a sample of households large enough to provide an adequate basis for obtaining national and regional estimates of fertility. As a first step towards meeting this very important objective of the survey, provisional estimates of age-specific fertility rates are provided here and compared with estimates for previous years.

The study of differences in fertility by social, geographical, and other components of the population is a primary concern of all fertility surveys. In addition to its descriptive utility, the identification of the direction and magnitude of fertility differentials is an essential first step towards an understanding of the determinants of fertility. A major portion of this section is devoted to a discussion of such differentials, both in cohort and in current fertility.

Fertility in Korea has experienced a remarkable decline in the last decade, which coincides with the period of intensive, public and private efforts in the promotion of family planning and rapid economic growth. Korean fertility remained at a traditionally high level through World War II and the Korean War (1950-53). The crude birth rate is estimated to have ranged from 40 to 45 per thousand as recently as when the 1960 census was taken. The average annual rate of increase in population between 1955 and 1960 was 2.9 per cent, compared to 1.7 per cent between 1970 and 1975. Fertility behaviour has been transformed greatly since 1960. Deliberate fertility control began among women in the late reproductive ages in cities and then gradually in rural areas as well. Between 1960 and 1970, the crude birth declined from about 43 per thousand to about 29 per thousand, and the total fertility rate from 6.0 to 3.9. By 1974, the crude birth rate was reduced to about 25 per thousand, and the total fertility rate dropped to 3.5. Reduction occurred in both urban and rural areas of the country. This fertility decline is especially significant in view of the general consensus in Korea that it is desirable to reduce the rate of population growth in order to achieve an accelerated rate of economic growth and social development.

3.5.2 CUMULATIVE FERTILITY BY BIRTH OR MARRIAGE COHORT

There are two sources of data on births in the Korean survey: the household schedule and the individual questionnaire. In the household survey, the numbers of all live births and of surviving children by sex for each ever-married woman regardless of age the date of birth, sex, and survivorship of the most recent live birth were obtained. In the individual survey, a detailed

history of births and other pregnancies was obtained for each woman interviewed, covering the outcome and date of each event, the sex and survivorship of each live birth, and the date of death, if any, of a child. These data permit the calculation of a number of fertility measures, including both cumulative measures such as the number of children ever born or living and current measures such as age specific fertility rates. The discussion of findings starts with a consideration of the cumulative measures. They are considered in relation to the age of woman, her marital duration, and the age at first marriage.

A. AGE OF WOMAN (BIRTH COHORT)

The mean number children ever born by age of woman, obtained from the household survey (the individual survey yields the same estimates) are shown in Table 23, with comparable figures from the censuses of 1966 and 1970. In all but the youngest and the oldest age groups, there is a declining trend from 1966 to the present survey year (1974). Interestingly, the mean number of children for the oldest age group (45-49) which could be taken as measure of completed family size, does not show a decline, though the overall average shows a slight decline from 3.8 in 1966 to 3.6 in 1974. Decline was both somewhat more pervasive in the different age groups and greater between 1966 and 1970 than between 1970 and 1974.

The age differentials based on data for a given year must be interpreted with caution, of course, as the age groups represent different birth cohorts. For example, those in the ages 45-49 in 1974 were about 40-44 in 1970 and 35-39 in 1966. Thus, this particular birth cohort can be seen as having progressed in number of births from about 4.9 in 1966 to 5.3 in 1970 and 5.8 in 1974. By contrast, it is wrong—strictly speaking—to assume that those who are 35-39 in 1974 would progress from their current mean number of births of 4.1 to 5.1 and 5.8 in the next two quinquennial periods. In a period of declining fertility, it is more likely that progression would be much slower with the result that the completed family size for each birth cohort that still has some years left in their reproductive life span would end up being smaller than that shown for the oldest birth cohort.

TABLE 23. MEAN NUMBER OF CHILDREN EVER BORN BY AGE OF EVER MARRIED WOMEN: 1974 HOUSEHOLD SURVEY AND CENSUSES OF 1966 AND 1970

Age	1966 ¹⁾ CENSUS	1970 ²⁾ CENSUS	1974 ³⁾ HHS

B. DURATION OF MARRIAGE (MARRIAGE COHORT)

The relationship between cumulative fertility and length of marriage is shown in Table 24, which presents the number of children ever born by years since first marriage for all ever married women interviewed in the individual survey. The steady rise in cumulative fertility with duration of marriage follows an expected pattern, though the rise must not be interpreted as the experience of a single cohort at different durations of marriage. The categories of the variable, years since first marriage, represents different marriage cohorts subject to differential circumstances and experiences.

The high fertility of those married 20 or more years age is noteworthy: more than half have had 6 or more children. It is not likely that the younger cohorts would end up with such high fertility as they eventually complete their reproduction. The prevalence of primary sterility, measured by the frequency of zero parity women, is low in Korea: less than 3 per cent of the women in any duration-of-marriage category above 5 years has been without any children to data, presumably due to the most part to involuntary causes. The high rate of zero parity (24%) among those married less than 5 years is, on the other hand, more a function no doubt of their recency of marriage rather than of fecundity impairment.

TABLE 24. PER CENT DISTRIBUTION OF ALL EVER-MARRIED WOMEN ACCORDING TO NUMBER OF CHILDREN EVER BORN, BY YEAR SINCE FIRST MARRIAGE

Years since first marriage	Number of children ever born										Total	Mean
	0	1	2	3	4	5	6	7	8	9+		
0-4	24.0	44.6	28.9	(2.3)	*	*	—	—	—	—	100.0	1.1

C. AGE AT MARRIAGE

As age at marriage in conjunction with current age defines duration of marriage, a strong association between fertility and age at marriage is expected within each age group. It is evident from Table 25 that age at marriage has been a major determinant of completed fertility. Average completed family size, or its approximation as measured by the mean number of children ever born to women in the ages 45-49, varies from 6.9 for those who married before age 15 to 4.3 for those who married in the ages 20-24.

Within each marriage duration, the mean number of children ever born is larger the earlier the age at marriage—but only if the number of years since marriage has exceeded 10 years. (See lower panel of Table 25.) Among those married only recently (less than 10 years ago), there is virtually no difference as yet in cumulative fertility by age at marriage.

3.5.3 DIFFERENTIALS IN CUMULATIVE FERTILITY

There is evidence in census and survey results of differential fertility among Korean women by several socioeconomic characteristics. These include differences according to place of residence, level of education, labor force participation, occupation, standard of living, and so forth. The study of such differences is important not only for an understanding of current and possible future levels of fertility, but also as a first step in understanding fertility behaviour as such.

A. DIFFERENCE BY SIZE OF COMMUNITY

The large household survey sample permits us to examine the differences in mean number of children ever born by size of community of residence. Table 26 summarizes the data. Seoul has the smallest mean in each age group where comparison is possible. The rest of the cities, including Pusan, follow in order, with little systematic differences by size of city. The towns and villages have the largest means again in every age group where meaningful comparison is possible.

Similar differentials are found in data from the individual survey, which permits the examination of the mean number of children ever born by years since first marriage by type of current residence. (See Table 27.) The category "city" includes Seoul, Pusan, and the various-sized cities of the classification used for the household data in Table 26 above. The definitions of towns and villages are the same as in that table. Except for the most recently married, the mean number is consistently smallest for the city residents in every marital duration group, followed by the town and the village residents in that order. The differences widen with length of marriage.

TABLE 26. MEAN NUMBER OF CHILDREN EVER BORN TO ALL EVER-MARRIED WOMEN, BY SIZE OF COMMUNITY AND AGE; 1974 HOUSEHOLD SURVEY

Size of community	Age							
	All ages	15-19	20-24	25-29	30-34	35-39	40-44	45-49
Seoul	2.8	(0.4)	0.8	1.7	2.8	3.6	4.0	4.9

Time series comparison of the 1974 survey results with data from the censuses of 1956 and 1970 shows that fertility has declined in both urban and rural areas though at a somewhat faster rate in the former as compared to the latter. (See Table 28.) It should be cautioned that the changes in age composition in the different types of place are not considered in these comparisons.

TABLE 28. MEAN NUMBER OF CHILDREN EVER-BORN BY URBAN AND RURAL RESIDENCE: 1974 KNFS COMPARED TO CENSUSES OF 1966 AND 1970

Place	1966 ¹⁾ CENSUS	1970 ²⁾ CENSUS	1974 ³⁾ KNFS
Urban	3.4	3.1	3.0

 3) 1974 KNFS, Table 2.2.5B

Those who grew up in cities, regardless of where they now live, have lower fertility than those who grew up in towns and villages, according to Table 2.2.7M. This is shown by the fact the mean number of children varies little by current place of residence among those who spent their childhood in cities. By contrast, among those who grew up in towns and villages, their current place of residence makes considerable difference in their fertility; it is consistently lower for the city residents than for the town and village residents. The data for all ever-married women are presented in Table 29. These patterns are replicated in each duration of marriage group, as can be seen in Table 2.2.7M, though less clear-cut in the most recently married group.

B. EDUCATIONAL DIFFERENCES

A considerable amount of research exploring the relationship between fertility and education is available. It is generally the case that education and fertility are inversely related, and the expectation is that rise in educational level of a population in the course of social and economic development will contribute to overall decline in fertility.

From the household survey, we find the mean number of children ever born to be related inversely with education in every age group where meaningful comparison is possible. (See Table 30.) The differences widen with advance in age. Similar inverse patterns are evident in the comparison of the mean number of children ever born to the women interviewed in the individual survey within each marital duration group. (See Table 31.) The differences are small in the most recently married groups but widen with length of marriage.

TABLE 30. MEAN NUMBER OF CHILDREN EVER BORN TO ALL EVER-MARRIED WOMEN, BY EDUCATION AND AGE: 1974 HOUSEHOLD SURVEY

TABLE 31. MEAN NUMBER OF CHILDREN EVER BORN TO ALL EVER-MARRIED WOMEN, BY WIFE'S EDUCATION AND YEARS SINCE FIRST MARRIAGE

Education	Years since first married							
	All durations	Less than 5	5-9	10-14	15-19	20-24	25-29	30+
No schooling	5.3	1.5	2.9	4.1	5.0	5.6	5.7	6.6
Primary	3.6	1.2	2.8	3.9	4.5	5.1	5.5	5.8
Middle	2.2	1.0	2.7	3.2	3.7	4.4	5.3	5.7
High	2.4	1.0	2.4	3.0	3.4	4.3	4.4	4.5
College or higher	2.3	1.2	2.3	2.7	3.1	4.1	2.8	5.0
All women	3.5	1.1	2.7	3.7	4.4	5.1	5.5	6.3

Source: 1974 KNFS, Table 2.2.5A

Time series data, summarized in Table 32, show the persistence of the inverse pattern in 1966, 1970, and 1974, with little change over time within each category of education. The overall decline from 1966 to 1974 in the mean number of children ever born to all ever-married women, it appears, is in good part due to the changing educational distribution (i. e., the general rise in the educational level) during the period. Age-controlled analysis is needed for a more conclusive generalization.

TABLE 32. MEAN NUMBER OF CHILDREN EVER BORN BY EDUCATIONAL ATTAINMENT: 1974 KNFS COMPARED TO CENSUSES OF 1966 AND 1970

Education	1966 CENSUS ¹⁾	1970 CENSUS ²⁾	1974 KNFS ³⁾
No schooling	5.0	5.2	5.3
Primary	3.3	3.7	3.6
Middle	2.7	2.6	2.2
High	2.3	2.2	2.3
College or higher	2.3	2.2	2.3
All women	4.2	4.1	3.6

 3) 1974 KNFS, Table 2.2.5A

Educational differentials are greater than the differentials by type of place of current residence, as can be seen from Table 2.2.7A. Though the number of cases with secondary education or

better diminishes rapidly the older the marital cohort (implying the recency of improvement in educational opportunities for women in Korea) and makes meaningful comparison difficult when controlled for marital duration, the trend is clear: within each duration of marriage group, the differences in the mean number of children ever born are greater between educational categories than between categories of type of place of residence. The pattern that is apparent in Table 33 for all ever-married women is replicated in every marital duration group as can be seen in detail in Table 2.2.7A.

TABLE 33. MEAN NUMBER OF CHILDREN EVER BORN TO ALL EVER-MARRIED WOMEN, BY EDUCATION AND TYPE OF PLACE OF CURRENT RESIDENCE

C. OCCUPATIONAL DIFFERENCES

Occupation of the husband is perhaps the most widely used index of socioeconomic status in the study of differential fertility. For all the tabulations in this report which relate a woman's cumulative fertility to characteristics of her husband, the number of children ever born to the wife includes children not only from her present marriage but also children from any previous marriages. Differentials by husband's occupation in Table 27 shows markedly large numbers of children ever born to agricultural workers; this clearly reflects their exclusively rural background. The professional and managerial workers do not necessarily show the lowest fertility, though the manual workers—the unskilled, in particular—show a fertility level that ranks only behind the agricultural workers if married 15 years or longer.

These patterns persist even when the wife's educational level is taken into account. (See Table 2.2.7C.) Where there are enough cases to make meaningful comparisons, those whose husbands are in agriculture tend to have the highest fertility within each educational category, though the differences are substantially reduced. Within each occupational category, education makes a considerable difference. In fact, education in general has a stronger influence on fertility than does occupation as witness the patterns for all ever-married women in Table 34. These patterns are replicated in every duration of marriage group, as can be seen in detail in Table 2.2.7C. For example, among those whose husbands are in agriculture, the women with no schooling had an average of 5.7 children as compared to 4.0 for those with primary education and 2.6 for those with middle school education. Similar patterns are found within each occupational category, though in every case the differences are diminished especially in the less-than 10-year group once duration of marriage is taken into account.

Occupational differences persist also within type of place of current residence. (See Table 2.2.7K) Those in agriculture generally have the highest fertility whether living in a city, town, or village. While the pattern is virtually non-existent among the most recently married (say, within the last 10 years) and only moderately evident in the intermediate marriage durations

(10-19 years), it is clearly revealed among those married 20 years or more. Generally, however, the occupational differences are smallest for those residing in cities and largest for those residing in villages. This results from the fact that urban residence regardless of occupation tends to be associated with lower fertility.

TABLE 34. MEAN NUMBER OF CHILDREN EVER BORN TO ALL EVER-MARRIED WOMEN, BY WIFE'S EDUCATION AND HUSBAND'S OCCUPATION

Source: 1974 KNFS, Table 2.2.7C

D. DIFFERENCES BY WIFE'S WORK STATUS

In the discussion about ways to encourage low fertility, increasing female labour force participation is often mentioned. Many studies have been concerned with the association between woman's work status and her fertility. The type of occupation, if not labour force participation as such, has been found to be related to fertility. In general, if they work at all, women in white colour and professional occupations tend to have smaller families than women in blue colour and service occupations, while agricultural workers are characterized by relatively high fertility.

In Korea, the agricultural sector has claimed the largest proportion of the labour force, though giving way in recent years to other sectors. In the present survey, agriculture still occupies a substantial portion of the working force: 35 per cent of the husbands and 54 per cent of the wives who had ever worked were most recently employed in agriculture.

The data in Tables 2.2.5E, 2.2.7E, and 2.2.7L do not show that the wives with work experience as a group have lower fertility than those who never worked, whether we control for years since marriage, education, or type of place of current residence. Only if the most recent work was in the category "professional and clerical" is the fertility generally lower than those who never worked. (See Table 35.) By and large, those whose most recent work was in sales and service or manual employment show levels of fertility that are similar to those who never worked, except in the longest marital duration (20 years or more) where the former have lower fertility than the latter. Those in agriculture, the most numerous group, have substantially higher fertility than all others in every duration of marriage category.

These findings suggest that wife's labour force participation takes many forms and have diverse effects on fertility. The complex relationships defy adequate explanation at this stage of analysis. The importance of this variable, with definite policy implications, justify its inclusion in the topics to be further investigated at a later date. The main questions to be answered are: What type of employment (e.g., at home vs. away from home) as well as what type of

TABLE 35. MEAN NUMBER OF CHILDREN EVER BORN TO ALL EVER-MARRIED WOMEN, BY WIFE'S MOST RECENT OCCUPATION AND YEARS SINCE FIRST MARRIAGE

Wife's most recent occupation	Years since first marriage			
	All duration	Less than 10 years	10-19 years	20 years or more
Never worked	2.8	1.7	3.7	5.2
Professional and clerical	2.0	1.4	(2.7)	*
Sales and service	3.4	1.9	3.7	4.7

Skilled and Unskilled manual	3.3	1.7	3.7	4.7
All women	3.6	1.8	4.1	5.6

Source: 1974 KNFS, Table 2.2.7H

occupation is associated with low fertility? What is the relationship of the length of employment and fertility? Is employment influenced by fertility itself that is, do married women work because of either high or low (say, involuntary childlessness) fertility? Is work experience away from home in the period prior to marriage an important factor? etc.

E. RELIGIOUS DIFFERENCES

The relationship of religion to fertility is erratic at best, as can be seen in Table 27. The apparent tendency of the two Christian groups towards low fertility when the mean number of children ever born is compared for all ever-married women is not born out consistently when duration of marriage is controlled. The converse of this is that the Buddhists do not necessarily have higher fertility than the rest when the difference in marriage duration is taken into account.

3.5.4 FERTILITY IN THE FIRST FIVE YEARS OF MARRIAGE

The examination of the number of children born in the first five years of marriage is important in at least two respects:

- (1) First, it enables us to examine historical change, if any, in the tempo of early fertility when compared between marriage cohorts, and
- (2) Second, it allows us to examine the relationship, if any, between age at marriage and fertility in the early stages of marriage.

The analysis is of course restricted to those who had been married for at least five years. Table 36 shows the mean number of children born in the first five years of marriage by age at marriage within broad marital duration groups. What is striking is that the tempo of early marital fertility is somewhat faster in the more recent marital cohort. The overall pattern that shows higher early fertility for the younger cohort is replicated in every age at marriage group. The implied faster tempo of childbearing in the younger cohorts is further substantiated by Table 37, where the mean length in months from first marriage to first birth is shown. Overall, it took on the average 26.5 months from marriage to first birth among those married 20 years ago but only 16.5 months for those married less than 10 years ago. This cohort pattern is replicated in general even when age at marriage is taken into account. Some of the

cohort differences displayed in Tables 36 and 37 could be due to recall lapse associated with the older cohorts. On the other hand, the faster tempo of childbearing in the more recent cohorts could be explained by improvement in fetal mortality, decline in breastfeeding, or ever more frequent premarital conceptions, among other factors. For example, Table 4.1.1, 4.1.6 shows that breastfeeding is less frequent among the younger women and Table 2.1.1, that more of the more recently married have had their first births within 7 months of marriage (implying premarital conceptions) than the older cohorts. The cohort differences in the proportion of first births occurring within 7 months of marriage is substantial: 10.9 per cent among those married 5 to 9 years ago; 5.9 per cent among those married 10 to 19 years ago, and 2.2 per cent among those married 20 or more years ago.

TABLE 36. MEAN NUMBER OF CHILDREN BORN WITHIN FIRST FIVE YEARS OF MARRIAGE TO WOMEN MARRIED AT LEAST FIVE YEARS, BY AGE AT FIRST MARRIAGE AND YEARS SINCE FIRST MARRIAGE

Years since first marriage	Age at first marriage						
	All ages	Less than 15	15-17	18-19	20-21	22-24	25 and over
5-9	2.0	*	(1.8)	1.8	2.0	2.1	2.1
10-19	1.7	*	1.5	1.7	1.8	1.8	1.9
20 or more	1.3	0.9	1.2	1.5	1.4	(1.5)	*
All durations	1.6	0.9	1.2	1.6	1.8	1.9	2.0

Source: 1974 KNFS, Table 2.1.2A

Generally the later the age at marriage is, the faster is the tempo of early fertility. For example, the mean number of live births within the first five years of marriage was 0.9 for those married at less than 15 but 2.0 for those married at age 25 or later. (See Table 36.) The mean length from marriage to first birth was 32.1 months for the former and 16.5 months for the latter. (See Table 37.) These patterns are replicated in the two older marriage cohorts (10-19 years and 20 years or more) but reduced to virtual non-existence in the youngest. The especially slow tempo of births in the early years of marriage for those who married at less than 15 or even those who married at less than 18, probably reflects the influence of adolescent sterility known to be a factor in these early ages in many populations.

TABLE 37. MEAN LENGTH IN MONTHS FROM MARRIAGE TO FIRST BIRTH FOR WOMEN MARRIED AT LEAST FIVE YEARS, BY AGE AT FIRST MARRIAGE AND YEARS SINCE FIRST MARRIAGE

Years since first marriage	Age at first marriage						
	All ages	Less than 15	15-17	18-19	20-21	22-24	25 and over
5-9	16.5	*	(19.7)	19.4	16.6	16.4	16.3
10-19	19.5	*	26.0	21.2	18.5	16.8	15.9
20 or more	26.5	33.2	29.0	23.5	22.1	*	*
All durations	21.1	32.1	28.0	21.8	18.4	15.5	16.5

Source: 1974 KNFS, Table 2.2.1

Differentials in fertility in the first five years of marriage by background characteristics are small, if they exist at all. The data are summarized in Table 38. There are slight indications that the tempo of early fertility might be faster for the better educated and those who worked before marriage in professional and clerical occupations than the others when we look at

the overall differences, but once marital duration and age at marriage are taken into account the differences are virtually non-existent except perhaps for those married 20 years or more. (See Tables 2.1.2A and 2.1.2D for detailed comparison by age at first marriage by years since first marriage.)

TABLE 29. MEAN NUMBER OF CHILDREN BORN WITHIN FIRST FIVE YEARS OF MARRIAGE TO WOMEN MARRIED AT LEAST FIVE YEARS, BY BACKGROUND CHARACTERISTICS AND YEARS SINCE FIRST MARRIAGE

Background Characteristics	Years since first marriage			
	All duration	5-9	15-19	20 or more

3.5.5 CURRENT FERTILITY

In Korea in the absence of a reliable vital statistics reporting system, current fertility rates such as the crude birth rate, age-specific fertility rates and total fertility rate, among others, must necessarily be estimated from periodic sample surveys and the quinquennial national censuses. The present survey permits us to calculate all the standard rates, though in this report we discuss in preliminary fashion only the age-specific fertility rates and the total fertility rate. Two other, indirect measures of the current level of fertility that can be obtained from the survey are the mean number of births in the past five years and the proportion reporting at interview a current pregnancy. These too will be examined briefly.

The exercise of estimating age-specific fertility rates from a retrospective sample survey is not without its hazards. However, it is still worthwhile to attempt a preliminary estimation of these rates prior to the necessary but time consuming methodological refinement that is planned for a later date. The estimates are based on a relatively simple procedure. First, the most recent births of the 17,167 ever-married women in the ages 15-49 who were enumerated in the 21,253 households comprising the household survey were classified by date of birth and those occurring in the twelve months preceding the survey date (a total of 2,716 births), distributed by the mother's exact age at interview. The age distributed births would constitute the numerators in the calculation of the age-specific fertility rates. The use as denominators the

number of ever-married women in each of the age groups would yield us age-specific marital fertility rates (ASMFR). For the calculation of age-specific fertility rates (ASFR), the number of all women regardless of marital status in the given age group is used as the denominator. The calculated rates are summarized in Table 39.

TABLE 39. AGE-SPECIFIC FERTILITY RATES AND AGE-SPECIFIC MARITAL FERTILITY RATES: 1974 HOUSEHOLD SURVEY

Age	No. of births	No. of ever married women	No. of all women	ASMFR ^{a)}	ASFR
15-19	63	190	5,765		
20-24	673	1,891	4,233	353.7	10.9
25-29	1,102	3,601	3,999	306.0	159.0
30-34	550	3,302	3,348	166.6	275.6
35-39	242	3,251	3,272	74.4	164.3

Total	2,716	17,157	25,555	4.7 ^{b)}	3.6 ^{b)}

a) per 1,000 women

b) Total fertility rate per woman

Source: 1974 KNFS, HHS Table II.1, II.3

The "total" figures in the last two columns in Table 39 are, of course, the total fertility rates for ever-married women and all women, respectively. A total fertility rate (TFR) represents the number of live births that could be expected of a woman if she were to go through her

7) 1974 KNFS, HHS Table, II-8

reproductive years from 15 to 50 exposed to the risk of childbearing represented by the schedule of age-specific fertility rates of a given 12 month period. It should be emphasized that these are tentative estimates based on all too simple assumptions. More refined estimates will be prepared at a later date after the quality of birth and age reporting is systematically assessed. The refined estimates will take into account births and women who inevitably missed in a retrospective survey due, for example, to deaths in the preceding 12-month period and because it is based on a sample drawn from non-institutional populations, etc.

In spite of the preliminary nature of the estimates, it is remarkable that they are consistent with past trends based on estimates for earlier years from various sources. Table 40 shows the various estimates going back to 1960. While there are some irregularities, the basic trend is one of consistent decline in every age group. Figure 9 represents the basic pattern of decline when the estimates for 1968 and 1970 are arbitrarily removed from the comparison.

The percentage decline in the ASFR for each age group and the TFR from 1960 to 1974, is presented in Table 41. Both Figure 9 and the data summarized in Table 41 show that decline has been substantial in every age group but particularly in the youngest ages 15-19 a result primarily due to postponement of marriage and in the ages above 30, with the consequence that the TFR declined by as much as 40 per cent in the 14 year period from 1960 to 1974.

The decline in the ages above 30 is clearly due to voluntary control within marriage as marriage has been nearly universal in these ages. (See Section 3.4.2 above.) In terms of the TFR's, the decline has been nearly as great in the 3-year period between 1971 and 1974 (18%) as in the 5-year period between 1966 and 1971 (19%) and substantially greater than in the 6-year period between 1960 and 1966 (10%).

The 1974 household survey, because of its fairly large sample size, affords us an opportunity to examine the ASFR's and the ASMR's—and the accompanying TFR's—by the woman's level of education and the size of community where she resides. Tables 42 and 43 summarize the data. While these rates too must be taken as preliminary estimates, the patterns of differentials observed here by these characteristics should hold even when the rates are refined at a later date.

The differences in the TFR's, based on the ASFR's for all women regardless of marital status, by the woman's level of education are substantial, as can be seen in Table 42: they go from 4.8 for those with no schooling down to 2.5 for the college educated. Much of the differences in the TFR's is due to the differences in the ASFR's for the ages below 25 and above 30. In these

FIGURE 9. AGE-SPECIFIC FERTILITY RATES, 1960-1974

Source: Table 41 above.

ages, the ASFR's are substantially lower the higher the education. The differences are especially marked between those with primary level education or less and those with middle school education or more.

The TFR's based on the ASFR's for only the ever-married women by level of education vary in the expected direction (lower the more education) but the differences are much smaller than in the case of the TFR's based on the ASFR's for all women: they go from 5.3 for those without any schooling to 4.4 for the college-educated. The reduced range of variation is due to the fact that the ASFR's within marriage for ages under 20 vary but little by level of education. The comparison of the ASFR's and ASMFR's reveals that a good part of the educational differences in the TFR's for all women is due to the differences in proportion who are married in the ages under 25. It is clearly suggested that the better educated have a substantially lower proportion married in these ages as compared to the less educated. This is consistent of course with the findings reported earlier in Section 3.3.4.

Variation in the TFR's by size of community is also quite substantial. (See Table 43.) The contrast between Seoul, the rest of the cities, and the rural communities (towns and villages) is marked especially when the TFR's based on the ASFR's for all women regardless of marital status are compared. These TFR's are 2.6 for Seoul and range from 2.9 to 3.6 for other cities and from 4.0 to 4.4 for the rural communities. The TFR's based on the ASFR's for married women only vary in the same direction but within a much narrower range: 3.8 for Seoul, from 4.1 to 4.4 for other cities, and from 4.8 to 5.3 for the rural communities.

TABLE 44. AGE-SPECIFIC FERTILITY RATES BY URBAN AND RURAL RESIDENCE, 1960-1974
(per 1,000 women)

Year	Age of women							TFR (per women)
	15-19	20-24	25-29	30-34	35-39	40-44	45-49	
	Urban							
1960	22	223	316	250	184	81	--	5.4
1966	4	119	278	209	92	48	8	3.7
1968	6	113	297	169	77	28	--	3.5
1970	8	141	258	141	63	18	3	3.1
1971	3	166	316	196	91	29	--	4.0
1973	7	104	284	195	50	13	--	3.3
1974	6	135	262	129	42	13	2	2.9
	Rural							
1960	48	291	354	308	237	115	--	6.7
1966	16	243	424	284	228	96	12	6.5
1968	8	178	305	220	147	87	11	4.8
1970	17	189	291	212	126	50	7	4.4
1971	9	211	363	266	144	49	4	5.2

1974	16	192	298	206	103	41	4	4.3

Source: Table 40 above.

The differentials by size of community generally show up for each ASFR, though they are reduced considerably when the ASMFR's are compared. Unlike the situation with level of education, the differentials by size of community cannot be explained away as much by the proportion married in the youngest ages.

Table 44 compares the ASFR's and the TFR's by broad classification of community types-urban and rural-for period 1960-74. While decline is clearly evident in both urban and rural areas, it has been substantially greater in the former than in the latter. The TFR declined in the urban areas by 46 per cent from 5.4 in 1960 to 2.9 in 1974 as compared to 36 per cent from 6.7 in 1960 to 4.3 in 1974 in the rural areas. The 1960-74 decline in the ASFR was considerably greater in the urban than in the rural areas in every age group but 20-24 and 25-29, as can be seen from the comparison in Table 45.

3.5.6 MEAN NUMBER OF LIVE BIRTHS IN THE PAST FIVE YEARS AND PROPORTION CURRENTLY PREGNANT

The level of current fertility can be measured indirectly by the mean number of live births in the past five years and by the proportion reporting a current pregnancy. Table 46 shows the former by number of living children for the 3,827 women who had been continuously in the married state during the five years preceding the date of interview. Table 47, on the other hand, shows by number of living children the proportion among all currently married women who report a current pregnancy.

The mean number of live births is larger for younger women, as might be expected (See Table 46.). Also the mean is larger the fewer the number of living children at the beginning of the five-year period. And, of course, the proportion with less than two children, for example, is higher in the younger ages. (See Table 2.4.1.)

Overall, 11 per cent of the currently married women report a current pregnancy. (See Table 47.) Some underreporting is expected, of course. Some women in the early stages of pregnancy would not be aware of their status; a few might be reticent about admitting a pregnancy for a variety of reasons but especially if an abortion is contemplated. In any case, taking the reported figures at face value, we do find that this proportion too is greater the younger the women.

Source: 1974 KNFS, Table 2.4.5

The proportion is as high as 29 per cent and 28 per cent for those in the ages 15-19 and 20-24, respectively, but declines rapidly after these ages to one per cent or less in the ages 40 and over. Furthermore, the proportion reporting a current pregnancy is much higher if the women has had no living children (42%) or only one (23%) than if she has had two or more. And, as we noted before, low parity is associated with the younger ages. (See Tables 2.4.1 or 2.4.5) No particular pattern is discernible in the mean number of children born in the past five years by several background characteristics. (See, for example, Tables 2.4.3A-F.)

3.5.7 SUMMARY

1. This section focussed on the trends and differentials in fertility measured in cohort or current terms. Both the household survey and the individual survey were used as data sources.
2. The ever-married women ages 15-49 enumerated in the household survey reported an average of 3.6 live births, which is slightly lower than the averages for all ever-married women in these ages enumerated in the 1966 (3.8) and the 1970 census (3.7). There is evidence of a declining trend since 1966 in all ages except under 25 and 45 and over. The decline was greater between 1966 and 1970 than between 1970 and 1974.
3. The recency of a high fertility pattern in Korea is reflected in the fertility level of those in the individual survey who had been married for 20 years or more: more than half have had 6 or more children. The younger cohorts are not likely to achieve such high level of fertility as they complete their fertility in the years ahead.
4. Involuntary childlessness, reflecting primary sterility seems low in Korea: less than 3 per cent of women in any duration of marriage category above 5 years have been without any children to date. The high rate of childlessness (24%) among those married less than 5 years is more a function of their recency of marriage than of fecundity impairment.
5. Age at marriage has a strong association with fertility, as expected. For example, the mean number of children ever born to women in the ages 45-49 varied from 6.9 for those married before age 15 to 4.3 for those who married at ages 20-24. Within each marital duration category, the mean number of children ever born is larger the earlier the age at marriage if the number of years since marriage has exceeded 10 years. There is virtually no difference as yet among those married more recently.
6. Differentials in cumulative fertility were examined with data from both the household survey and the individual survey.

a. By size of community

- (1) From the household data, the mean number of children ever born is smallest for Seoul and largest for the towns and villages with the means for the rest of the cities, including Pusan, in-between but showing no systematic differences by size of city. These differences persist within age groups where meaningful comparison is possible.
- (2) From the individual interview data, the city residents show the smallest mean number of children ever born and the village residents the largest. The differences are as yet virtually non-existent in the most recently married group but they widen with length of marriage. Those who grew up in cities, regardless of where they live now, have lower fertility than those who grew up in towns or villages. This pattern also persists in every marital duration group but is less clear-cut among the most recently married.

b. By education

- (1) Both household data and the individual survey data show that the number of children ever born is inversely related to level of education attained by the woman. This pattern persists in every age and marital duration group, with the differences widening with increasing length of marriage.
- (2) Educational differentials are greater than the differentials by type of place of residence in every duration of marriage group, suggesting that educational improvement can facilitate removal of geographical differences in fertility by the diffusion of small family norms associated with better education. In fact, there is a hint, based on limited observation, that the overall decline in fertility since 1966 may have been due more to a change in educational distribution (i. e., the general rise in educational level attained) than to decline in fertility within any specific educational categories.

c. By husband's occupation

- (1) The individual survey data show that fertility is highest for those whose husbands are in agriculture, reflecting their nearly exclusive rural background. The differences among other occupations are inconsistent at best, though for those married 15 years or longer the manual workers, the unskilled in particular, tend to show a level of fertility that ranks only behind the agricultural works.
- (2) Education in general has a stronger influence on fertility than husband's occupation, though occupational differences are not completely removed by education. This is the case in every marital duration group.
- (3) Occupational differences persist within each type of place of residence, although they tend to be smallest for those residing in cities and largest for those residing in villages. In short, urban residence regardless of occupation tends to be associated with lower fertility.

d. By wife's work status

- (1) The individual survey data do not show that women who had work experience either before or after marriage have lower fertility than those who never worked.
- (2) The only meaningful relationship so far observed is between fertility and the type of most recent occupation the women has had. Generally speaking, only if the most recent work was in professional or clerical positions is fertility lower than for those who never worked. On the other hand, those most recent work was in agriculture have the highest fertility as compared to all others. This is true in every marital duration category.
- (3) Further detailed analysis of the relationship between wife's pattern of work and fertility is recommended both because of the importance of the topic and because of the apparent complexity of the relationship as revealed in the data so far tabulated for this report.

e. By Religion

The data from the individual survey show no systematic relationship between religion and fertility. Patterns that seem to exist are not replicated once duration of marriage is taken into account.

7. Fertility in the first five years of marriage was examined with data from the individual survey to see (1) if there is any historical (i.e., cohort) changes in the tempo of early fertility and (2) if there is any relationship between age at marriage and early fertility.

- a. The findings suggest that the tempo of early fertility is faster for the most recent cohorts women as compared to the older cohorts, though generalization must be tempered by the possibility of under-reporting due to certain amount of recall lapse among the older cohorts. The number of months between first marriage and first birth was 16.5 months on the average for those married less than 10 years ago as compared to 26.5 months for those married 20 years ago. The cohort pattern represented in these differences holds true even when age marriage is taken into account.

The apparent tendency for faster tempo of early fertility among the more recent cohorts is consistent with the improvement in fetal mortality, decline in breastfeeding, or more frequent premarital conception—all of which could be documented from this or other studies.

- b. The findings also suggest that generally the later the age at marriage the faster is the tempo of early fertility. The mean number of live births born within the first five years of marriage was 0.9 for those married at less than 15 but 2.0 for those married at age 25 or later. The mean length from marriage to first birth was 32.1 months for the former and 16.5 months for the latter. These patterns hold true in any significant way only for those in the older cohorts. Adolescent sterility is probably responsible for the slower tempo of early for those who married at extremely young ages.

- c. Differentials in fertility in the first five years of marriage by background characteristics are small, if they exist at all. Most of the differences disappear when marital duration and age at marriage taken into account.

8. Current fertility was measured directly by age-specific fertility rates (ASFR's) and the attendant total fertility rate (TFR) from the household survey and indirectly by the mean number of live births in the past five years and the proportion reporting a current pregnancy from the individual survey.

- a. The age-specific fertility rates were calculated without adjusting for under-reporting of births and women inherent in a retrospective, cross-section survey with a sample drawn from non-institutional populations. They are offered as preliminary estimates pending further refinement at a later stage. The estimated ASFR's per 1,000 women by five year age group are: 15-19, 11; 20-24, 159; 25-29, 276; 30-34, 164; 35-39, 74; 40-44, 29; and 45-49, 3. The estimated total fertility rate per women is 3.6. These rates are remarkable in their consistency with estimates for recent years from other sources.

- b. Comparing the ASFR's estimated from the present survey with those estimated for 1960, we noted that decline has been substantial in every age group over the past 14 years but particularly in the youngest ages, presumably due to postponement of marriage, and in the older ages, due to voluntary control of fertility within marriage. The decline has been more rapid in the more recent period, 1971-74, as compared to the earlier periods, 1960-66 and

1966-71. The decline and its acceleration coincided with the period of intensified efforts, both public and private, in the promotion of family planning and rapid economic growth.

9. The 1974 household survey, because of its large sample size, permits the calculation of ASFR's by woman's level of education and size of community where she resides. We can summarize that the TFR's based on the estimated ASFR's are lower the higher the educational level attained and the larger and more urban the community of residence. A comparison of the ASFR's based on all women regardless of marital status and those based on only the ever-married reveals that the differentials in age at marriage can account for much of the differences by education though not so much the differences by size of community.
10. A comparison of the decline between 1960 and 1974 in the ASFR's and the TFR in the urban and the rural areas show that it has been substantially greater in the former than in the latter area in most age groups but especially in the ages under 30 and in the ages 35 and over. Both later age at marriage and greater control of fertility within marriage would seem to account for the greater rate of decline in these rates in the urban areas over these years.
11. Both the mean number of children born in the past five years (to women continuously in the married state during the five years preceding the survey) and the proportion reporting a current pregnancy among all currently married women are higher the younger the women and the fewer the number of living children. The proportion currently pregnant among all currently married women was about 11 per cent; it is as high as 29 per cent and 28 per cent for those in the ages 15-19 and 20-24, respectively, but declines rapidly after these ages to one per cent or less in the ages 40 and over.

There is no particular pattern discernible by background characteristics in these indirect measures of current fertility.

3.6 SURVIVORSHIP OF CHILDREN

3.6.1 INTRODUCTION

In order to place findings on fertility preferences and behavior in their proper context it is useful to know, in broad outline at least, the impact of infant and child mortality on family size. Indeed, the historical trend and current level of infant mortality is a topic of great interest and importance in its own right, especially in Korea where data is scarce and substantial declines have likely occurred over the past 20 to 30 years. Though it would be unwise to attempt to estimate a historical trend from the present survey before the data have been subjected to a more thorough appraisal, estimates of the current or recent levels of infant mortality have been derived from information relating to births in the several years preceding the survey. Another set of data, comparisons of the number of living children to the number of live births for women of different ages, provide further insight into survivorship, though many of the tables relating to this section are purely descriptive presentations of the number of living children for different birth and marriage cohorts.

3.6.2 INFANT MORTALITY

Within any population, a relatively high rate of mortality prevails during the first years of

life. The infant mortality rate is a sensitive indicator of the health conditions enjoyed by a community, and the level of infant mortality is generally associated with mortality levels at older ages.

As a preliminary estimate of infant mortality, a crude measure based on the ratio of deaths in a given year to children under one year of age to all births occurring in that same year is offered.¹² Table 48 presents the estimates on a single-year basis going back from 1973 to 1964 and as three year moving averages of these single-year estimates. Infant deaths are known to be underreported and the more so, the further one goes back in time. Estimates based on a cross-section sample survey also suffer from the exclusion of mothers (and their children) who did not survive to be interviewed. The trend depicted in Table 48 is, however, quite reasonable even if these deficiencies are not taken into account in calculating the estimates. The rates estimated by others for some of these same years agree fairly closely with those presented here, as can be seen in Table 48 and in the footnote attached to it. It is probably safe to conclude that the infant mortality rate in Korea has declined from about 50 in the late 1960's to a little over 30 in the early 1970's.

3.6.3 THE EFFECTS OF MORTALITY ON FAMILY SIZE

A brief look at the effects of mortality on family size is provided in Table 49. The average number of live births reported by all women was 3.6 with 3.2 still living at the time of interview. About 11 per cent of the live-born children were reported as deceased by interview date, thus yielding an overall survival ratio of 89 per cent. The proportion surviving declines from 95 per cent for women in the ages 25-29 to 81 per cent for women in the ages 45-49. This decline in survival ratio by woman's current age reflects the obvious fact that the children of older women have had longer exposure to the risk of dying and also the declining trend in

12) This ratio expressed as the number of infant deaths per year per 1,000 live births during the same year is sometimes referred to as the "conventional infant mortality rate" as distinguished from the "adjusted infant mortality rate" based on the probability of dying within one year of birth of an actual birth cohort of a given year. See Henry S. Shryock, Jacob S. Siegel, and Associates, *The Methods and Materials of Demography*, Vol. 2, Washington, D.C.: U.S. Bureau of the Census, 1971, pp. 410-411, for a discussion of the methodology and some of the limitations of the measure.

period rates of infant and child mortality. The relatively low survival ratio (80%) of children for women under 20 years of age is noteworthy and merits further investigation.

In further analysis, it should also prove interesting to see if survivorship of children varies with background characteristics. Unfortunately no tables bearing on this topic were prepared for this report to permit a preliminary glimpse of the possible differentials.

3.6.4 SUMMARY

1. Infant mortality rates were estimated for the past few years on the basis of infant deaths reported in the birth history obtained in the individual survey. The estimates are based on a crude procedure which simply takes the ratio of the deaths in a given year to children under one year of age to all births occurring in that same year.
2. On the basis of the crude measures from the present survey and other available estimates, we conclude that infant mortality rate in Korea has declined from about 50 per 1,000 live births in the late 1960's to a little over 30 in the early 1970's.
3. The average number of live births reported by all women in the individual survey was 3.6 with 3.2 still living at interview. This represents an overall survival ratio of about 89 per cent, or a rate of loss to death of about 11 per cent.

Survival ratios of children is obviously related to the age of women, going from 95 per cent for those in the ages 25-29 to 81 per cent for those in the ages 45-49. The survival ratio for those under 20 is noticeably low (80%) indicating that further study may be justified in exploring the reasons for this phenomenon.

For this report no effort was made to compare the survival ratios of children by the mother's background characteristics. Such an analysis would obviously have to be done with age of mother appropriately controlled in as much as the survival ratio is in part a function of time both in terms of length of exposure to risk of death and the secular trend in period rates of infant and child mortality.

3.7 PREFERENCES FOR NUMBER AND SEX OF CHILDREN

3.7.1 INTRODUCTION

With the widespread knowledge and availability of family planning methods in Korea, preferences for size and sex composition of a family become important factors in determining levels of fertility. In this section these factors are examined using data on the respondent's stated preferences for number and sex of their children. In Sections 3.7.2, 3.7.3, and 3.7.4, variables on desired and prospective family size are cross-classified by age and number of living children, and in Section 3.7.5 differentials by several background characteristics are examined. In Section 3.7.6 the effect on preferences of the current sex composition of the family is considered. A major problem in this area concerns the stability and predictive value of the answers to the questions of preference and attitude which form the basis of the data. The problem is compounded by the use of different words and questions in the different surveys to elicit responses in this general area. For example, with reference to questions on total family size preference, the effect of the use of different words such as "desire," "expect," or "ideal" on the response is difficult to assess, especially when results are compared across survey. In view of this, it is recommended that the results and especially interpretation with regard to trends be treated with caution.

3.7.2 THE DESIRE TO LIMIT FAMILY SIZE

The question as to whether additional children were wanted or not was asked of only the currently married who were neither sterilized nor subfecund. The question was not asked of those who reported that they could not have any (or any more) children because such a question would have been irrelevant and of those not currently married because it was deemed inappropriate or even improper. It was also not asked of any woman who was sterilized for contraceptive purposes or whose husband had a vasectomy. They were, however, classified as being fecund and not wanting any more children as willingness to undergo sterilization for contraceptive purposes could be construed as a most convincing demonstration of the desire to limit family size. The word "fecund" in the titles of such tables as 3.1.1, 3.1.2, and 3.1.3 A-D, among others, and of Table 50 in the text must be read with this qualification in mind—namely, that it includes those sterilized for contraceptive purposes.

The question on desire to limit family size was asked in two different ways depending on whether the woman was currently pregnant or not. If she was not currently pregnant, she was asked:

"Do you want to have another child some time?"

If currently pregnant, she was asked:

"Do you want another child some time, in addition to the one you are expecting?"

Only 46 respondents (1%) reported that they were undecided about wanting more children. Seventy-two per cent did not want to have any more children, leaving only 27 per cent wanting additional children. The response to this question varies of course with the number of living children the women already has. In Table 50, the number of living children includes current pregnancies on the assumption that they would lead to live births.

From the first row of Table 50, it can be seen that about two-thirds of the respondents with two children did not want another child, and for respondents with three children the percentage increases to 86 per cent. The desire to limit the number of children to two or three appears widespread, but very few women (13%) are content with less than two. Within each parity, the desire to limit family size increases with age. Few women want additional children if they are past 35 years of age or married at least 10 years already—especially if they have had at least one child.

TABLE 50. PERCENTAGE OF CURRENTLY MARRIED "FECUND" WOMEN WHO WANT NO MORE CHILDREN, BY NUMBER OF LIVING CHILDREN, AGE, AND MARITAL DURATION.

	Number of living children						
	All parities	0	1	2	3	4	5 or more
All women	72	13	13	66	86	92	96
Age:

30 or more	97	—	*	*	*	*	98

Source: 1974 KNFS, Tables 3.1.1, 3.1.2

A finding with possible programmatic implications is that nearly one-fourth of the women aged 20-24 and over one-half of those aged 25-29 say they do not want any more children. Sterilization, generally concentrated among older women toward the end of their reproductive years, may well be encouraged among women in their twenties where the long-term demographic effect (e.g., the number of births averted) would be greater.

3.7.3 ADDITIONAL NUMBER OF CHILDREN WANTED

Currently married fecund women wanting no more children were assigned a value of zero for the variable "number of additional children wanted," while those who wish to have another child were asked how many additional children they wanted. From Table 3.2.1, we observe that the mean number of additional children wanted decreases with increasing parity and with increasing age within each parity. The mean for the entire sample is 0.4 and 2.1, 1.3, 0.4, and 0.2 for respondents with 0, 1, 2, and 3 children, respectively. At each parity, the less educated and rural women desire more additional children than their more educated or urban counterparts. (See Tables 3.2.3, and 3.2.5)

Perhaps one of the main interests concerning this variable lies in the answers of young respondents with low parities, where the sum of the number of living children and the number of

additional children wanted can be compared with a more idealized measure, total desired family size, to check for agreement. This is considered in Section 3.7.4 to follow.

3.7.4 TOTAL DESIRED FAMILY SIZE

All women in the sample were asked the question:

"Now, if you could choose exactly the number of children to have in your whole life, how many children would that be?"

The answer to this question is defined as the "total desired family size" and is distinguished in this report from the "total wanted family size," or "prospective family size," which is the sum of the number of living children a woman has and the number of additional children wanted. The per cent distribution of respondents according to "total desired family size" by age and marital duration for the currently married is shown in Table 51.

TABLE 51. PER CENT DISTRIBUTION OF CURRENTLY MARRIED WOMEN ACCORDING TO TOTAL NUMBER OF CHILDREN DESIRED, BY AGE AND MARITAL DURATION

	Total number of children desired							Total	Mean
	0	1	2	3	4	5 or more			
All women	—	2	24	41	20	13	100	3.2

Source: 1974 KNFS, Table 3.3.4, 3.3.6

Nearly two-thirds of the respondents would like two or three children, with an additional one-fifth desiring four. The mean desired family size increases with both age and marital duration. It is not possible to interpret these trends directly as indicating cohort differences because of the tendency for the desired size to be influenced to some extent by the actual family size. (See Table 3.3.3 A-B, for example.) There is, in other words, suggestion that the total desired family size reflects to some extent rationalization of achieved fertility.

In Tables 3.3.4 A-B and 3.3.5 A-B, for example, we find that age and marital duration differences in mean desired family size exist in any consistent way only in the parities 0 and 1 and only erratically in parity 2—that is, the mean is higher the older women or the longer the marital duration only in these parities. These results could be interpreted in two ways. On the one hand, the absence of cohort differences in the higher parities suggests the influence of parity on the statement of ideal size. On the other hand, the existence of cohort differences in parity 0 or 1 suggests a shift in norms about desired family size in as much as at these parities there is no possibility of an upward bias due to parity. The most marked difference is between those in the

age cohort of 45-49 and the remaining, younger cohorts. (In Section 3.7.5 below, we note some further suggestion of cohort differences within categories of background characteristics when the influence of parity is removed by a standardization technique.)

A comparison of the desired family size and the prospective family size (defined earlier as the number of living children plus the number of additional children wanted) presents an interesting picture. Table 52 summarizes the data by parity by age. In that table, the upper entry of each cell represents the mean desired family size and the lower entry the mean prospective family size. Note that the infecund respondents are excluded for the latter variable, and hence the sample bases for the upper and lower entries differ considerably for the older age groups. Nevertheless, the two variables in Table 52 provide an interesting comparison between an idealized measure of family size and a measure which takes into account children already born. For low parities, the ideal number of children appears slightly larger than the number the respondents actually want in practice, a finding often associated with the developed countries. With increasing parity, the number of children desired increases at a much slower rate than the number wanted, so that at high parities the prospective family size is much larger than the professed ideal. It is interesting to observe the cross-over point where the two numbers are roughly equal. This lies between 2 and 3 children for younger ages and drifts upward to lie between 3 and 4 children for older age groups. This rise could be due to a readjustment of goals as children arrive.

TABLE 52. MEAN DESIRED FAMILY SIZE (\bar{X}_D) AND MEAN PROSPECTIVE FAMILY SIZE (\bar{X}_P) COMPARED, BY NUMBER OF LIVING CHILDREN AND CURRENT AGE

Source: Mean desired (\bar{X}_D) from Table 3.3.4.B, based on ever-married women. Mean prospective (\bar{X}_P) from Table 3.3.4.A, based on currently married women

A notable feature of Table 52 is the relative stability of the mean desired family size from cell to cell, in spite of the slight tendency noted earlier for it to increase with parity. It appears that norms favourable to low fertility are quite well established, though actual fertility tends to exceed these norms.

From Table 3.3.3A, it can be calculated that 34 per cent of currently married women had a larger family than they wished. The percentage for each parity is as in Table 53.

TABLE 53. PERCENTAGE OF ALL EVER-MARRIED WOMEN WHOSE ACTUAL FAMILY SIZE IS LARGER THAN THE DESIRED SIZE, BY NUMBER OF LIVING CHILDREN

Number of living children	Per cent with larger family than desired
One	0
Two	1
Three	21
Four	54
Five	71
Six	90
Seven	98
Eight or more	93
All parities	34

Source: 1974 KNFS, Table 3.3.3.A

Over a fifth of the respondents with three children and over a half with four children seem to prefer fewer children than they already have. At parities 5 or higher, 71 per cent to 98 per cent would seem to prefer smaller families than they have. A similar picture emerges from a different source where attention is restricted to the last pregnancy. Currently married women with at least one live birth (or a current pregnancy) were asked if they wanted their last live birth (or current pregnancy), with the results as presented in Table 54.

TABLE 54. PERCENTAGE OF CURRENTLY MARRIED WOMEN WITH AT LEAST ONE LIVE BIRTH (OR CURRENT PREGNANCY) WHO DID NOT WANT LAST LIVE BIRTH (OR CURRENT PREGNANCY) BY NUMBER OF LIVING CHILDREN

Number of living children	Per cent not wanting last live birth (or current pregnancy)

Four	49
Five	63
Six	75
Seven	81
Eight or more	87
All parities	37

Source: 1974., KNFS, Table 3.1.4

Nearly two-thirds of the women with five living children were willing to state that they did not want their last child. The proportion rises to as high as three-fourths at parity 6 and up to 87 per cent for those who had eight or more living children. Even at lower parities, nearly one-fourth stated at parity 3 that they did not want their last child. The result is that more than a third (37%) of the currently married women in Korea with at least one live birth or who were pregnant at interview did not want their last live birth or their current pregnancy.

115

When age and marital duration are introduced in the comparison, as in Tables 3.1.4 and 3.1.5, we find that this pattern for all women is replicated in every age and duration-of-marriage group, and at a given parity the proportion not wanting the last live birth or the current pregnancy generally rises with both age and length of marriage. The pattern by age for all parities, for example, is presented in Table 55.

TABLE 55. PERCENTAGE OF CURRENTLY MARRIED WOMEN WITH AT LEAST ONE LIVE BIRTH (OR CURRENT PREGNANCY) WHO DID NOT WANT THE LAST LIVE BIRTH (OR CURRENT PREGNANCY) BY AGE

Age	Per cent not wanting last live birth (or current pregnancy)
15-19	0
20-24	8
25-29	16
30-34	33
35-39	48
40-44	58

3.7.5 DIFFERENTIALS IN FAMILY SIZE PREFERENCE

The examination of differentials in family size preference by background characteristics is complicated by the fact that family size preference, as we noted, is influenced by age and parity and that age and parity compositions vary by background characteristics. Several tables have been prepared for the purpose of analyzing the differentials by controlling for age and parity, but due to the number of factors involved in the cross-tabulations and the limited sample sizes in the numerous cells meaningful comparison is very difficult. To overcome this difficulty and to facilitate the desired analysis, a technique of standardization is introduced to remove at least the effect of number of children. This is done by assuming that women in each category of background variable and age are distributed by number of living children as the women in the total sample. In short, family size preference to be compared by background variable, controlled for age, is standardized on the parity distribution of the women in the total sample.

In applying the standardization technique, those with four or more children and those 45 years of age and over are excluded since only a handful of them want more children—about 6 per cent and 3 per cent of currently married fecund women in these categories, respectively. The standard distribution used was the distribution of women in the total sample with 0, 1, 2, and 3 living children and was applied to only three 10-year age groups 15-24, 25-34, and 35-44.

Table 56, 57, and 58 summarize the results, giving the standardized percentage who want no more children, the standardized mean additional number of children wanted, and the standardized mean desired family size. To illustrate the interpretation of these tables, consider in Table 56 the entry 39 per cent for primary education in ages under 25. This estimates the proportion who want no more children for a hypothetical population of women under age 25 with primary education and a distribution on parity equal to that of the entire sample, excluding those with 4 or more living children. Differences between the cells have a simpler interpretation, being estimates of differentials in response controlling for differences in parity distribution across the cells. We can summarize the main findings from Tables 56 as follows:

TABLE 56. PERCENTAGE OF CURRENTLY MARRIED "FECUND" WOMEN WHO WANT NO MORE CHILDREN, BY BACKGROUND CHARACTERISTICS AND AGE, STANDARDIZED FOR NUMBER OF LIVING CHILDREN^{a)}

7.2	24.2	33.0	35.7	100.0% (n=2,831)

Source: 1974 KNFS, Tables 3.4.6A-F.

1. Proportion not wanting any more children increases with education for age groups under 35. Differential: between educational groups are negligible for the oldest age group.
2. More of the city residents (61%) want no more children than the village residents (47%). This differential is replicated in the 25-34 age group but absent in the ages under 25. The town residents seem to resemble the village residents more than the city residents. This is certainly the case in the ages 25-34 group where there are enough cases to make the comparison reliable.
3. Religion does not appear to be a major determinant of family size intention in Korea. If anything, fewer of those who profess no religion tend not to want any more children as compared to any of the religious groups. This no doubt related to both education and place of residence.
4. Wife's pattern of work, as with religion, appears generally not to be related in any significant way with desire for more children. In the youngest age group, there is, however, a differential by whether the women ever worked or not. The proportion not wanting any more children is higher for those who never worked (52%) as compared to those who worked at one time or another (36-45%). Further analysis is needed to determine whether this difference results from differences in such other factors as education and community background.
5. The data for husband's occupation show a markedly greater desire for more children among the agricultural and unskilled manual workers than for any other groups. This seems true regardless of age, though full comparison is possible only for the age group 25-34.

Overall, the data summarized in Table 56 show that more of the less educated, rural residents want additional children than the better educated, urban residents, particularly in the younger ages.

The data in Table 57 show further that the mean number of additional children wanted is higher in just those groups where additional children are more often wanted: the less educated, the village residents, those professing no religion, those who have ever worked, and those husbands are either agricultural or unskilled manual workers. These differentials exist generally in each age group.

We noted in the preceding section that norms favourable to low fertility seem to be well established in Korea. Within a narrow range, however, there are some significant differentials by several background characteristics. Table 58 summarizes the data, standardized for parity to remove its influence in the statement of the ideal. It is noteworthy, first of all, that there is no apparent indication of cohort differences in the idealized family size norm. Earlier we tried to suggest the existence of cohort differences but cautioned ourselves in interpreting the data because of the possible upward bias associated with parity and hence with age for the older cohorts. Here we have data standardized on parity, though for a somewhat restricted sample. The differences by age broadly grouped do not suggest the existence of a declining pattern in ideal family size norm in recent years. The data are presented in Table 59.

Within several categories of background variables, however, there appears to be a hint of a decline in ideal family size as we move from the oldest to the youngest cohort. Among village residents, for example, the mean desired family size declines from 3.31 for those aged 35-44 to 2.93 for those under age 25. (See Table 58.)

By background characteristics themselves, we find the following differentials, though it must be

repeated, within a fairly narrow range (Table 58):

1. The better educated tend to prefer a smaller family size than the less educated. Within each age group, the differences are diminished somewhat but the general pattern is still in evidence.
2. The city residents prefer a smaller family size than the village residents, with the town residents in-between. The differences are diminished only slightly for the youngest age group.
3. Religious differences are minimal. Interestingly, the Catholics seem to prefer the smallest family size, though this is merely a hint based on small differences.
4. Currently working wives tend to prefer a slightly larger family size than the others. This pattern is replicated in every age group. This probably is a function of the heavy rural composition of the currently working women.
5. Wives whose husbands are agricultural workers have the highest preference, followed by unskilled manual workers. The high preference of the agricultural workers shows up in every age group. The number of cases are too few for the unskilled manual workers to make any comparison within age group.

TABLE 59. MEAN DESIRED FAMILY SIZE BY AGE FOR ALL EVER-MARRIED WOMEN, STANDARDIZED FOR NUMBER OF LIVING CHILDREN

Age	Mean desired family size
Under 25	2.80
25-34	2.75
35-44	2.89
All ages	2.81

Source: Table 58 above.

In Table 58, the higher preference is found among the unschooled, village residents, currently working, and those whose husbands are in agriculture. By contrast, the lowest preference is found among those who had at least middle school education, city residents, those who worked only before marriage, and those whose husbands are in non-agricultural occupations, including the skilled manual workers. These differentials are similar in direction, though much smaller in magnitude, as the differentials with respect to achieved fertility. (See Section 3.5.3) If achieved fertility were to follow closely the idealized preferences, the differentials could be narrowed substantially.

3.7.6 PREFERENCES RELATED TO SEX OF CHILDREN

In societies where there is a traditional preference for male off-springs, it is of interest to look at the family size preferences of women according to their current number of sons and daughters. In Korea, such a preference exists, although it has declined in recent years with the rising status of women and increasing opportunities for them. In Table 60, where the percentage wanting no more children is shown for currently married, fecund non-pregnant women, the strength of male preference is clearly indicated. For example, close to half the women still want additional children even if she already has three or more children but no sons. On the other hand, 77 per cent say they don't want any more children if they have two children and all of them are sons. It is interesting to note that virtually no one wants more children if she has

two sons with at least one daughter, or at least three sons regardless of whether she has any daughters, or at least one son if she has four or more daughters.

Among the minority of women who want another child, two out of three desire to have a son. (See Table 3.4.3.A.) The remainder (35%) are equally divided between those desiring a daughter and those expressing no preference.

Further analysis of sex preferences will be possible when data from the Coombs' scales (Q. 606-611 in the individual questionnaire) are processed.

3.7.7 TRENDS IN FAMILY SIZE PREFERENCE: COMPARISON WITH PREVIOUS SURVEYS

Comparison of the results from the present survey with those from previous surveys is complicated somewhat by the alternative definitions used for the relevant variables. For example, in the surveys of 1965, 1968, 1971, and 1973 preferred family size was elicited in terms of the ideal for women of Korea in general as against the personal reference used in the present survey. (See Appendix 9 for exact wordings used in the different surveys.) Table 61 compares the preferred family size between surveys, with a note of caution about the strict comparability of the 1974 data.

The declining trend from 1965 to 1973 is impressive as it is clear-cut—from 3.9 to 3.1. The decline from 1971 to 1973 was quite steep. Only 27 per cent in 1973 gave four or more children as ideal as compared to 52 per cent in 1971. The mean for 1974 shows no decline from 1973, however. There are relatively more women giving one or two children as the preferred family size in 1974 than in 1973 (26% vs. 21%), but this is offset by the larger proportion giving four or more children as the preferred size in 1974 (33% vs. 27%).

The variable "percentage of women not wanting any more children" is directly comparable from survey to survey. Table 62 summarizes the data. Two-thirds do not want any more children in 1974 if they had two children, as compared to less than half in previous surveys. More than 90 per cent want no more children in 1974 if they had at least four children. That high a proportion not wanting additional children was not reported in previous surveys unless the women had at least five children in 1973 and six or more children in 1967 and 1968. If the comparison in Table 60 was inconclusive, these results from Table 62 suggest that family size preference has indeed declined substantially in recent years.

TABLE 61. PER CENT DISTRIBUTION OF CURRENTLY MARRIED WOMEN ACCORDING TO "IDEAL" NUMBER OF CHILDREN: 1974 KNFS COMPARED TO PREVIOUS SURVEYS IN 1965, 1968, 1971, AND 1973

3.7.8 SUMMARY.

1. This section examined the trends and differentials in family size and sex preferences based on the individual survey.
2. A large majority (72%) of the currently married, fecund women stated that they did not want any more children when directly asked about it. The proportion not wanting any more children was low (13%) if the woman has had less than 2 children to date but rises to about two-thirds if she already has had two and to 86 per cent if she has had three. The preference for about 2 to 3 children is clearly indicated.
3. Within each parity, the desire to limit family size increases with age. Few want additional children if they are past 35 years of age, especially if they have had at least one child. A finding with possible programmatic implication is that nearly one-fourth of the women aged 20-24 and over one-half of those aged 25-29 say they do not want any more children. Sterilization could very well be encouraged among them, with strong demographic impact should these young women accept.

4. The mean number of additional children wanted decreases, of course, with increasing parity and with increasing age within parity. At each parity, the less educated or rural women tend to want more additional children than the better educated or urban women.
5. The question about total desired family size was asked of all women in the sample. Nearly two-thirds said they would like to have 2 or 3 children: "if [they] could choose exactly the number to have in [their] whole life." An additional one fourth stated a preference for 4 children. The mean desired family size for all women was 3.2.
6. While there is some indication that the total desired family size rationalizes to some extent the family size already attained, there is considerable convergence of the stated desired sizes around a narrow range of 2 to 3 children. One-third of the currently married women admit to having had more children than they desire. Over a fifth of those with 3 children and more than half with 4 children would have preferred fewer children than they already have. About 37 per cent of currently married women with at least one live birth or a current pregnancy admitted that they did not want their last pregnancy. While the proportion stating that they did not want their last pregnancy rises rapidly beyond 50 per cent after four children, nearly one-fourth even at parity 3 admitted to not wanting their last pregnancy. Within each parity, this proportion rises with both age and marital duration.
7. Differentials in the desire for additional children and the total desired family size by background characteristics were examined after removing the effect of parity composition by a standardization technique. Overall, the analysis reveals that more of the less educated, rural residents, whose husbands are in agriculture want additional children and more of them on the average than the better educated, city residents, whose husbands are in non-agricultural occupations other than unskilled manual work. The total desired family size too varies by background characteristics in ways similar to the differentials in the desire for additional children. The lowest preferences are given by the better educated, city residents, whose husbands are in non-agricultural occupations. While the currently working (who are mostly in agriculture) tend to prefer larger families than those not working, the women who had worked before marriage only, who tend to be concentrated in the younger ages, prefer smaller families.
8. The desire for additional children is influenced strongly by the sex composition of the children already born. More women express a desire for additional children, the fewer the number of sons they have-up to a point. If the total number of children exceeds two, most women would prefer not to have any more children, if they have at least one son. On the other hand, if they have no sons, only 23 per cent say they do not want any more children, though this proportion exceeds 50 per cent if they have 4 or more children altogether.
9. Both cohort trends in the present survey within several background characteristics and time series data from previous surveys show declines in "ideal family size", though the variable is defined somewhat differently in the different surveys. While the means for 1973 (3.1) and 1974 (3.2) are at nearly the same level, they both represent a substantial decline from 1965 (3.9). On the basis of a more directly comparable variable, "the percentage of women not wanting any more children," the preference for smaller family size in 1974 as compared to previous years is clear-cut. For example, in 1974, two-thirds of the respondents at parity two stated they did not want any more children as compared to less than half in previous surveys.

3.8 CONTRACEPTION, LACTATION AND ABORTION

3.8.1 INTRODUCTION

A wide range of information about contraception and related topics was collected in the survey. In addition to the standard WFS questions on knowledge, ever-use and current use, a complete history of contraceptive practice was obtained in Section 5 of the questionnaire. Also, details concerning the source of supply and side-effects experienced for users of the pill, loop and condom were elicited in Section 4. The WFS abortion module, in which an attempt is made to find out whether each non-fertile pregnancy was induced or spontaneous, was employed. Finally, the length of lactation for each live-birth was ascertained.

Full presentation of this wealth of data is beyond the scope of this preliminary report and, in any case, would require careful prior appraisal of the quality of response. Accordingly, attention has been confined to the standard WFS tabulations, though some preliminary tables on abortion have been added because of its importance in Korea.

The section follows a logical sequence of subjects—from knowledge of contraceptive methods, to ever-use and current use, and to summary measure of each respondent's experience of contraception by means of a composite variable "pattern of contraceptive use". The subject of contraceptive efficacy in the last closed and the open interval is briefly examined. Finally, the topics of breast-feeding and abortion are discussed.

3.8.2 KNOWLEDGE OF CONTRACEPTION

The definition of "knowledge" used in the survey, as in earlier surveys, merely implies that the respondent had heard of some method or of a particular method and no attempt was made to ascertain whether she knew how to use particular methods. Another important distinction concerns the dichotomy of methods into "efficient" and "inefficient". The former category covers those methods which are usually offered by official family planning programmes and are characterised by the recency of their development or widespread application. The pill, loop, condom, injection, male and female sterilization, and other female methods such as the diaphragm and foam tablets fall into this group. "Inefficient" methods include withdrawal, rhythm, douche, abstinence and miscellaneous others. With the obvious exception of abstinence, they are intrinsically less effective than the "efficient" methods.

Since the first Korean KAP survey in 1964, the proportion of married women with some knowledge of contraception has risen from about 50 per cent to over 90 per cent. In the present survey, 97 per cent of all ever-married women reported knowledge of at least one "efficient" method. (See Table 4.2.1.A.) There are slight differences in the prevalence of knowledge between demographic and socio-economic components of the sample, with the oldest, the least educated and rural women tending to have lower levels of knowledge than other groups. However, these differentials are not sufficiently marked to be of much practical importance. For instance, even among women aged 45-49, or those with no schooling, over 90 per cent had heard of at least one method.

The level of knowledge of particular methods are shown in Table 63. The pill and the loop were known by over 90 per cent of all women, while the condom and male and female sterilization had been heard of by substantial majorities. In contrast, "inefficient" methods are less well known, though underreporting can be expected in the case of withdrawal, if not for such other method as abstinence and douching.

TABLE 63. PERCENTAGE OF ALL EVER-MARRIED WOMEN WHO HAD HEARD OF AND EVER-USED SPECIFIC CONTRACEPTIVE METHODS

Method	Heard	Ever used
"Efficient" methods:		
Pill	94	33
IUD	91	24
Condom	75	22
Vasectomy	84	3
Female sterilization	66	2
Other female scientific methods	23	3
Injection	5	(1)
At least one "efficient" method	97	52
"Inefficient" method:		
Rhythm	58	16
Withdrawal	37	12
Douche	27	4
Abstinence	25	2
Others	3	(1)
At least one "inefficient" method	97	5

Source: 1974 KNFS, Tables 4.2.1.A, and 4.3.1A

3.8.3 EVER-USE OF CONTRACEPTION

Survey findings confirm the widespread use of contraception in Korea. Just over half (52%) of the entire sample had tried at least one of the "efficient" methods, and an additional 5 per cent had experienced an "inefficient" but never an efficient method. Thus, exclusive reliance on "inefficient" methods is uncommon in Korea. When tabulated by age and family size, the pattern of ever-use displays the familiar inverted "U" with a peak at the intermediate ages of 35 and 44 and intermediate family sizes of 3 to 5 children (See Figure 10). In this groups, the level of ever-use is about 70 per cent. The markedly lower level of contraceptive experience among the 45-49 age group (35%) is surprising in view of the relatively high levels of use recorded in the mid-sixties (44.2%) among the same birth cohort which was then ages 35-39. One explanation for the discrepancy is that older women are more susceptible to underreporting of use. The plausibility of this explanation is strengthened by the fact that reported levels of ever-use fall only a little in the 45-49 age group, when the figures are based on currently married women who consider themselves to be fecund, rather than on all ever-married women (See Table 4.3.1). It would not be surprising if women who have reached the menopause or have been widowed or separated under-report contraceptive use that may have occurred many years ago.

Data relating to differentials in ever-use are found in Table 4.3.2A. Educational level of respondents emerges as the characteristic most closely associated with use. Women with no schooling are much less likely to have tried any method than those who have attended school.

FIGURE 10-1 PERCENTAGE OF ALL EVER-MARRIED WOMEN WHO HAD EVER USED ANY METHOD OF CONTRACEPTION (INCLUDING STERILIZATION) BY CURRENT AGE

Source: 1974 KNFS, Table 4.3.1A

FIGURE 10-2 PERCENTAGE OF ALL EVER-MARRIED WOMEN WHO HAD EVER USED ANY METHOD OF CONTRACEPTION (INCLUDING STERILIZATION) BY NUMBER OF LIVING CHILDREN

Source: 1974 KNFS, Table 4.3.2A

while the primary school group has distinctly lower levels of use at each family size than better educated. Differences in the expected direction also exist between middle school, high school and college categories, but they are confined to women with small families. Among these better educated groups it appears that length of education may influence the timing of use.

Rural-urban differences are less pronounced than the educational ones. City residents with less than 4 living children report higher levels of ever-use than their town or village counterparts, but this distinction is not apparent among women with 4 or more children. There is little difference at any family size between the town and the rural components.

Differences between religious categories are very slight. The marginally higher level of ever-use among the Christians—both Protestants and Catholics—than among the Buddhists or the majority who reports no religious affiliation may well be due to their educational compositions. Differentials according to the occupation of the husband are more marked, though interpretation is rendered difficult by the link between occupation and wife's education. The professional and managerial group has the highest level of ever-use, but there is little consistent difference between the clerical, sales and service and skilled manual groups. Wives of husbands with agricultural and unskilled manual jobs report the lowest levels of ever-use.

Turning now to ever-use of particular methods, it can be seen from Table 63 that pill has been the most widely used method in Korea (33%) followed by the loop (24%), condom (22%), rhythm (16%) and withdrawal (12%) in that order. Experience to other methods has been confined to very small minorities.

3.8.4 CURRENT USE OF CONTRACEPTION

Though it is common to base estimates of the prevalence of current use of contraception on all ever-married women or currently married women, analytical precision is enhanced if women who are unexposed to the risk of conception are excluded. Accordingly, data on current use from this survey are based on currently married pregnant women who consider themselves to be fecund plus currently married women whose husbands, or who themselves, have been sterilized for contraceptive purposes. The inclusion of this latter group stems from the view that sterilization is akin to contraception and that sterilized couples may be considered as "exposed" current users. Thus, the exposed women differ from the "fecund" women only in the exclusion of the currently pregnant.

Of these 3,849, exposed women in the sample, 46 per cent were using a method of contraception at the time of the survey or had been sterilized for contraceptive purposes. As can be seen in Table 64, both age and family size are independently associated with prevalence of current use. Only 17 per cent of women with less than two living children were current users, but this proportion rises dramatically to 47 per cent for those with two children; thereafter it increases only slightly with increasing family size. This pattern suggests that there is scant reliance on contraception for spacing the first and second child. It is somewhat surprising that current use is not more strongly related to family size among those with 2 or more children, as one would expect that the desire for family limitation would be more intense for those with larger families and that this tendency would be reflected in contraceptive behaviour.

Within each family size group, current use tends to be highest in the 35-39 age group and rather lower among both older and younger women. The salience of the 35-39 age group is particularly marked among women with 3 or 4 children.

The sex composition of the family is also highly associated with current contraceptive practice. The data in Table 65 show that Korean couples are not likely to use contraception much unless they have at least 2 sons. But once they have 2 sons, use becomes quite frequent (60% or more) whether they have only 2 children, or 3, 4, or 5 or more. The absence of a daughter in the family is no deterrent to contraceptive practice. The desire for at least 2 sons still exerts a major influence on Korean fertility behaviour.

Differentials in current use by several background characteristics are summarized in Table 66. As with ever-use, educational level emerges as the background variable most closely (associated) with current use. With a few minor exceptions, the level of use within each family size rises with length of formal education. As many of the differences are substantial, it would seem that the convergence in contraceptive behavior between different educational groups, noted in earlier research, is still far from complete. Similarly, there are still large variations in current use between occupational categories. The professional and managerial worker are distinctive for their high level and the agricultural and manual workers for their low levels of use. However, no clear pattern of association between women's work experience and current use is discernible.

Differentials in current use according to type of place of residence and religion follow those previously observed for ever-use. The divergence between city residents and others is confined

to couples with small family sizes. However, the slightly higher levels of use of the Christians compared to non-Christians persist even among couples with larger families.

A breakdown of current users by particular method is shown in Table 67. The dominant positions of the pill and loop, which together comprise half of all use, can be clearly seen. The condom and rhythm are the next most prevalent methods; both methods are preferred more by those with small rather than large families. Sterilization accounts for 15 per cent of current users with vasectomy exceeding tubal ligation by a ratio of two to one. It is interesting to note that couples with four or more children are not more likely to accept sterilization than those with only three children.

Nearly a quarter (22%) of couples are relying on "inefficient" methods—mainly rhythm and withdrawal. The popularity of these methods compared to "efficient" methods does not vary according to family size. In other words, there is no evidence of switching to more reliable methods as the need to limit family size increases.

3.8.5 COMPARISON OF FINDINGS ON CURRENT USE WITH PREVIOUS SURVEYS

To enhance the comparability of findings on current use from the present survey with those of previous surveys, the 1974 data have been recomputed for all currently married women aged 15-44, which has been the normal mode of presentation in the past. Some previous national surveys have employed a universe of currently married women aged 20-44, but it is unlikely that the minor discrepancy in the base at the lower end of the age range will distort the comparison seriously.

As can be seen in Table 68, the prevalence of contraceptive practice among currently married women in Korea has nearly doubled since 1966 from 20 per cent to 37 per cent. Comparison of the 1974 survey with the one conducted in 1973 reveals few differences either in the overall level of use or in the use of particular methods. This similarity serves to raise confidence in the results of both of these surveys. There is, however, one interesting difference: in urban areas, use of the pill appears to have increased considerably between 1973 and 1974.

Similarly, the comparison between the 1973 and 1974 survey results for particular age groups reveals only one difference of sufficient magnitude to be of note (See Table 69). In the age group 30-34, there appears to have been a recent increase in current use.

Historical trends in current use by urban-rural residence and by education are presented graphically in Figure 11. The main conclusion from Figure 11-1, is that the slight urban-rural differential in current use has persisted for the last 10 years and shows no signs of reduction. In Figure 11-2, the trends for different educational sectors of the population must be interpreted with great caution because their age structures differ greatly and have changed over time. To take the most obvious example, the average age of the "no schooling" group has risen considerably since 1965, because of the near universality of primary education in Korea recent decades. A proper understanding of trends by educational level must therefore await a further analysis of the data, with controls for age and family size. Nevertheless, the present data set is of interest because it indicates an increase in use even among the "no schooling group" between 1973 and 1974.

3.8.6 PATTERN OF CONTRACEPTIVE USE

By means of a complex variable, "pattern of contraceptive use", an attempt is made to summarize in a concise form the contraceptive experience of all survey respondents. Women have been classified into three major groups-never, past and current users, with further subdivision within each group. As shown in Table 70, 43 per cent of the sample had never used any method, 24 per cent had used in the past but were not currently using, while the remaining 33 per cent were current users.

Never-users are sub-divided into three categories: those who stated an intention to use in the future (18 %), those who stated does not to use in the future (12 %), and, lastly, those who were not asked the question on intention because they are no longer fecund or currently married (14 %). It is evident from these figures that opposition to contraception is confined to only a small minority of Korean women.

Past but not current users are further classified according to recency of use: 4 per cent had used a method earlier in the open birth interval, 9 per cent in the last closed birth interval and 8 per cent in some earlier interval. A last group, comprising 4 per cent, are now infecund. (They too could have been classified by the interval in which they last used their contraception but were not as priority was given rightly or wrongly to their infecund status.) Current users are simply sub-divided into those sterilized for contraceptive purposes (5 %) and users of other methods (28 %).

Though it is a useful descriptive tool, most of the components of "pattern of use" have already been discussed in their own right and further commentary is unnecessary. The specialist reader can find a wealth of detail in Table 4.5.1. to 4.5.6 and 5.3.1 to 5.3.3. But there is one topic of fresh interest-namely future intentions which is further explored in Table 71. In this table, the proportions of ever-married never-users who intend to use in the future are displayed, with cross-classifications by number of living children (omitting those with 7 or more children because the sample sizes are too small) and three key background variables.

Overall, 60 per cent of these 1,620 women stated an intention to practice in the future, and this proportion does not vary according to family size. Variations according to background characteristics are similar to variations in contraceptive behavior; thus the least educated, the rural, and the wives of husbands with unskilled manual or agricultural occupations were slightly less likely to report intention to use than the others. However, the differences are slight and the general impression is of the absence of readily identifiable areas of resistance to family planning, assuming that intention will be uniformly translated into action.

3.8.7 CONTRACEPTIVE EFFICACY

Analysis of the effect of contraceptive practice on fertility and more particularly on the length of birth or pregnancy intervals is a complex subject, beyond the scope of this preliminary report. The present approach, which is restricted to an examination of the open birth interval and the last closed birth interval, is intended to serve as no more than an introduction. Nevertheless, the data summarized in Table 72 are of considerable interest.

The figures for the closed birth interval are based on the 4,568 women in the sample with 2 or more live or births (or one live birth and a current pregnancy). The mean length of the

interval for women who reported contraceptive use during the interval was 41.4 months compared to 35.5 months for those who did not use. This modest difference of 17 per cent holds for all age groups.

Data for open interval are based on the 3,428 women in the sample who were married, fecund, non-pregnant and had one or more live births. The picture that emerges from these figures contrasts markedly with that of the closed interval. Women who had used a method-excluding sterilization-in the open interval or were currently using a method, had on the average an open interval of 56.6 months, compared to 30.7 months for those who had not used a method since their last birth. This represents a difference of 84 per cent. Furthermore, the magnitude of this difference varies to a major extent across age groups. For women aged under 35, the open interval is about twice as long for users than non-users but the gap narrows for older women. This pattern of findings across age groups suggest the operation of selective forces by which the more fecund older women are more likely to be users than the less fecund. Thus, greater

TABLE 72. MEAN LENGTH OF LAST CLOSED BIRTH INTERVAL AND OPEN BIRTH INTERVAL BY USE OF CONTRACEPTION IN THE INTERVAL AND CURRENT AGE

Source: 1974 KNFS, Table 4.6.1 and 4.6.2

fecundity may be counter-balanced by greater use of contraception and the net effect is little divergence in the length of the open interval.

These results for the closed and open interval immediately suggest a low contraceptive efficacy for spacing purposes but high efficacy for termination of child-bearing. This tentative conclusion is consonant with other findings from the survey. However, induced abortion and lactation and their relationships to contraception may be crucial factors, which have not yet been explored. Furthermore, other factors, such as under-reporting of use in the last closed interval, may have distorted the results. Yet another factor which makes interpretation dangerous is the timing of contraception in relation to births. To the extent that initiation of contraception typically takes place a considerable period of time after the birth of a child, the high association between use and length of the open interval is misleading. On the other hand, if the converse is true-namely, that initiation of contraception takes place shortly after delivery, then the association may be even more pronounced than these preliminary data suggest. Further investigation using data for earlier intervals, together with abortion data, is clearly warranted.

3.8.8 LACTATION

The exact role of breastfeeding, or lactation, in delaying conception is not fully established, though there is widespread interest in its possibilities. It is not possible, of course, in this preliminary report to address this issue in any systematic way. Only a brief discussion is presented here, relegating an in-depth analysis that the topic deserves to a later date.

While the question on breastfeeding was asked for each birth in the Korean survey, tabulation for this report is restricted to the last closed birth interval-that is, the interval between the next-to-last birth and the last birth or the last birth and the expected date of delivery of a current pregnancy. The cases are perforce restricted to those with at least two live births or one live birth and a current pregnancy. To facilitate meaningful analysis, two further restrictions are introduced. A period of at least 24 months is set as the period of observation. This is to avoid the problem of censoring involved if shorter intervals were taken. Thus, the next-to-last child must have survived at least 24 months. As for the length of the closed interval itself, an additional 9 months are allowed to cover the period of gestation of the next child, since the closed interval is defined to end with the birth of a child rather than with conception. By allowing at least 33 months (24+9=33) for the closed interval, we avoid the downward bias on the duration of breastfeeding that can occur if we took a shorter interval of observation.

The restricted sample for whom item on breastfeeding could be defined totals 4,489, or about 83 per cent of the individual survey sample. Ninety-four per cent of the 4,489 women reported breastfeeding in the last closed interval. (See Table 4.4.1.) The mean length of breastfeeding in that interval was 19.2 months. The distribution by number of months of breastfeeding is summarized in Table 73.

There seems to be some tendencies for heaping in the categories of 12, 24, and 36, but basically most women breastfed for about a year to two years. About 16 per cent breastfed for more than two years and about 12 per cent for less than a year.

The proportion breastfeeding is somewhat higher for the older than the younger women (See Table 74) though the differences are small. The overwhelming majority of women in Korea, young or old, breastfed in the last closed interval. The mean length of breastfeeding, however, varies considerably by women's age and age at first marriage, as can be seen in Table 74. The older women and those who married before age 20 breastfed for a longer period than the younger women and those who married at age 20 or later. For example, those 45 and older and married

TABLE 73. PER CENT DISTRIBUTION BY NUMBER OF MONTHS BREASTFEEDING IN LAST CLOSED BIRTH INTERVAL, FOR WOMEN WITH AT LEAST TWO LIVE BIRTHS (INCLUDING A CURRENT PREGNANCY), RESTRICTED TO THOSE WITH CLOSED INTERVAL AT LEAST 33 MONTHS AND WHOSE LAST BIRTH SURVIVED AT LEAST 24 MONTHS

before age 20 breastfed for an average of 21 months as compared to 14 months for those under 25 and married at age 20 or later. These differences probably reflect cohort differences, but definite conclusions must await further analysis of the full range of data on breastfeeding available in the present survey.

Type of place of residence and education are strongly related to breastfeeding. (See Table 75). The trend appears to be that the city residents and the better educated are breastfeeding somewhat less often and for shorter periods. These differentials hold true especially for those with fewer than 4 children to date—namely, the younger women. Together with the age

TABLE 75. PERCENTAGE NOT BREASTFED AND MEAN LENGTH OF BREASTFEEDING IN MONTHS IN THE LAST CLOSED BIRTH INTERVAL BY TYPE OF PLACE OF RESIDENCE AND EDUCATION BY NUMBER OF CHILDREN EVER-BORN, CONFINED TO WOMEN WITH AT LEAST TWO LIVE BIRTHS (INCLUDING A CURRENT PREGNANCY) WHOSE LAST CLOSED INTERVAL IS AT LEAST 33 MONTHS AND WHOSE NEXT-TO-LAST CHILD SURVIVED AT LEAST 24 MONTHS

differentials observed in Table 74, these findings suggest that breastfeeding is perhaps becoming less popular among the younger, better educated, city residents. To what extent this trend, if it be real, would diffuse to the rest of the women in Korea is difficult to tell but it does raise some questions about the possible implications diminished breastfeeding may have on fertility, on the one hand, and nutrition and health of children, on the other.

Breastfeeding is believed by many to have a delaying effect on conception. Documentation of such an effect, however, is not always easy. Data so far tabulated from the present survey permits us to explore only in a very tentative way the possibility of such an effect for the women under study. We show in Table 76 the mean length in months of the last closed birth interval by number of months breastfed and whether or not contraception was used in that interval. Observation is restricted to those who had at least two live births, including a current pregnancy, and whose next-to-last child survived at least 24 months and whose last closed interval was at least 33 months but not longer than 5 years. The last restriction is introduced to remove those women whose birth interval may be prolonged due to subfecundity. Age control is necessary also to remove the possible effect of subfecundity associated with advance in age.

We focus our attention primarily on those who never used any contraception in the last closed interval in order to remove the effect of contraception on the length of that interval. (See upper panel of Table 76.) If breastfeeding was continued for at least 6 months, the length of the interval is longer than if there was no breastfeeding and the more so, the longer the period of breastfeeding. For example, for all ages, the mean length is 24.1 months for those who did not breastfeed as compared to 23.0 months for those who breastfed for less than 6 months but rises to 26.7 months for those who breastfed for 6 to 12 months and to as long as 35.1 months for those who breastfed for 24 months or longer. This overall pattern is replicated basically in every age group where meaningful comparison is possible.

TABLE 76. MEAN LENGTH IN MONTHS OF THE LAST CLOSED BIRTH INTERVAL BY NUMBER OF MONTHS BREASTFED AND USE OF CONTRACEPTION IN THAT INTERVAL, BY WOMAN'S AGE, CONFINED TO WOMEN WITH AT LEAST TWO LIVE BIRTHS (INCLUDING A CURRENT PREGNANCY) WHOSE LAST CLOSED INTERVAL WAS AT LEAST 33 MONTHS BUT NOT LONGER THAN 5 YEARS AND WHOSE NEXT-TO-LAST CHILD SURVIVED AT LEAST 24 MONTHS

Source: 1974 KNFS, Table 4.1.6

The mean length of the interval increases basically with longer period of breastfeeding if contraception is also used. (See lower panel of Table 76.) While cell sizes are too small in many cases to make much of the data, the basic pattern appears to be replicated within the age groups. Furthermore, a comparison of those who used contraception with those who did not suggests that roughly 3 to 4 months may be gained in the length of the interval by use of contraception over and above breastfeeding. (Compare the rows for all ages in the upper and the lower panels in Table 76.) Judging from the earlier findings with regard to the relative contraceptive efficacy associated with the open as against the closed birth interval, we may surmise that the gain of contraceptive use above the effect of lactation may be greater in the open than in the closed interval. Obviously much more careful and detailed analysis is needed for more definitive conclusions in this area.

3.8.9 INDUCED ABORTION

Abortion, whether legal or not, is known to be prevalent in many countries, and has a strong demographic impact. A particularly dramatic example is the rise in fertility in Romania in the 1960's following the enactment of restrictions on a previously liberal abortion law. Legalization of abortion or liberalization of abortion regulations have taken place in many countries in recent years, including Korea in early 1973. It is tacitly acknowledged that abortion is one of the critical factors affecting fertility levels in Korea.

Approval of abortion has become more widespread throughout Korea in recent years. For example, only about 16 per cent of a national sample of currently married women in the reproductive ages disapproved of abortion in 1973 as compared to as much as 45 per cent of a similar sample of women in 1971. The level of approval in 1973 was virtually the same in both urban and rural areas.¹³⁾

The use of abortion has increased by nearly two-fold since 1968, when a national estimate first became available. Table 77 shows the trends in the estimated proportion of women reporting ever-use of abortion by place of residence, according to the series of survey conducted since 1968.

Nation-wide, the proportion of currently married women in the reproductive ages reporting an abortion rose from 16 per cent in 1968 to 31 per cent in 1974. The rise was especially steep between 1968 and 1971. The estimated proportion has remained more or less stable since 1971. City residents have always reported higher proportion of abortion experience but the gain among the rural residents has been more than two-fold since 1968, with most of the gain having taken place between 1968 and 1971, just as for the nation as a whole.

TABLE 77. PERCENTAGE OF CURRENTLY MARRIED WOMEN AGED 15-49 WHO REPORT HAVING HAD AT LEAST ONE INDUCED ABORTION BY TYPE OF PLACE OF RESIDENCE: 1974 KNFS COMPARED TO SURVEYS TAKEN IN 1968, 1971, AND 1973

Table 78 shows for 1971 and 1974 the percentage of all ever-married women aged 15-49 who report having had at least one induced abortion by current age. There is a clear upward trend in every age group, though the most marked increases are found in the age groups 20-29 and 30-34. Most married women under age 20 have not yet achieved their desired family size and thus have as yet made little use of abortion. Women aged 45 and over have passed through most of their childbearing years during a period when ideal family size was larger than it has come to be in recent years and when abortion was much less common, but the rate for this age group increased from 19 per cent in 1971 to 26 per cent in 1974.

Source: 1974 KNFS, Tables 4.7.1, 4.7.2 and 4.7.3.

Collectively the women in the present survey reported an average of 0.6 abortion. While 30 per cent reported at least one induced abortion, 14 per cent reported two or more. (See Table 79.) The proportion of abortion users rises with the number of completed pregnancies, as might be expected, going from only 6 per cent among those with one completed pregnancy to 25 per cent among those with 4 and more than half among those with 6 or more. The mean number of abortions too rises with number of completed pregnancies. Neither the proportion of abortion users nor the mean number, however, rises monotonically with the number of living children beyond 3. Both figures reach a peak at 3 children and then decline. The highest figures are concentrated in the parities 3 to 5, suggesting that achieved fertility is to some extent a consequence of the use of abortion to keep it from increasing further. By age group, the highest proportion of those with abortion experience is found among those in their 30's and early 40's. More than one-third in these ages reported having had at least one induced abortion. About 22 per cent of those aged 35-39 and 20 per cent of those aged 40-44 had two or more.

The potential impact of induced abortion on achieved fertility can be gauged by an examination of the disposition of the pregnancies experienced by these women. Of the approximately 23,800 non-current pregnancies, reported by them, 14 per cent were terminated by an induced abortion. Five per cent were lost as stillbirths or miscarriages leaving 81 per cent ending in live births. These results vary only slightly from the situation in 1971. The Fertility and Abortion Survey of that year, based also on a national sample, showed 12 per cent termination by induced abortion, 6 per cent by stillbirth or miscarriage, and 82 per cent by live birth.¹⁴⁾

The results from the present survey for different age groups are shown in Table 80. The rate of termination by induced abortion is highest (at 15 %) in the age groups 25-34 and 35-44.

The low use of abortion in the ages 45 and over, seen in this and earlier tables, is consistent with the trends in fertility and abortion during their active reproductive years, but one suspects some underreporting too. Certainly the rate of termination by stillbirth or miscarriage is underreported in the older ages. One would normally expect this rate to rise with age in contrast to the result presented in Table 80. Obviously a careful assessment of these data are needed before a more systematic analysis of the role of induced abortion and other fetal losses can be pursued. Whatever observations we make in this report must be regarded as tentative.

TABLE 80. PER CENT DISTRIBUTION OF ALL NON-CURRENT PREGNANCIES ACCORDING TO OUTCOME BY WOMEN'S CURRENT AGE

Age	Per cent distribution by outcome			
	All non-current pregnancies	Live birth	Stillbirth or miscarriage	Induced abortion
Less than 25	100	84	8	8
25-34	100	79	6	15
35-39	100	80	5	15
40 and over	100	87	4	9
All ages	100	81	5	14

Source: 1974 KNFS, Marginal from Table 4.8.3A, 4.8.4A, 4.8.5A, and 2.2.6A.

Resort to abortion is closely associated with use of contraception. (See Table 81) Past and current users of contraception are more likely to have had an abortion than those who never used any contraception. For example, 41 per cent of past users and 48 per cent of current users as

14) See, *The Study of Abortion, 1971 Fertility-Abortion Survey Special Report*, Series, No. 2, Seoul: Korean Institute for Family Planning, April 1973, p.12. The data from Table III-8, based on ever-married women 15-54, were recalculated to obtain figures for ever-married women 15-49 for comparison with the results from the present survey.

against 11 per cent of those who never used reported having had an abortion. The highest proportion of abortion experience (88 %) is reported by those who used contraception in the open interval though not using at the interview. The next highest proportions are reported by past users who for various reasons have no need to use now (55 %) and the current users of methods other than sterilization (49 %). The number of living children does not make any difference in the proportion of abortion users except for the sterilized. While 48 per cent of the sterilized with less than 4 children reported having had an abortion, only 25 per cent of those with 4 or more children did so. It appears that use of abortion prior to sterilization helped these women to keep their achieved fertility relatively low.

On the right-hand side of Table 81, we show the percentage of non-current pregnancies terminated by induced abortion by pattern of contraceptive use. The rate of termination by abortion is higher for the users of contraception than the non-users, with the highest rates shown again for those who used in the open interval (20 per cent among current users and 38 per cent among past users). The rates are substantially higher for those who have less than 4 children than those who have more. This is true in every category of contraceptive use pattern but is especially marked for the current users: 31 per cent for those with less than 4 children as against 7 per cent with 4 or more children. There is strong hint in these data that use of abortion has helped in keeping the achieved fertility to below 4 children for many of these women but especially if it is combined with the use of contraception. A more definitive causal analysis must await further studies at a later date.

TABLE 81. PERCENTAGE OF EVER-MARRIED WOMEN WHO REPORT HAVING HAD AT LEAST ONE INDUCED ABORTION AND PERCENTAGE OF ALL NON-CURRENT PREGNANCIES TERMINATED BY INDUCED ABORTION, BY PATTERN OF CONTRACEPTIVE USE AND NUMBER OF LIVING CHILDREN

Pattern of contraceptive use	Per cent reporting an abortion			Per cent of non-current pregnancies terminated by abortion

Other methods	49	49	47	20	30	9

Source: 1974 KNFS, Tables 4.8.1A and 4.8.5A.

The differentials by background characteristics in the use of abortion are similar to what we observed earlier with respect to use of contraception. (See Tables 82 and 83) Both the proportion of abortion users and the rate of termination of pregnancies by abortion are substantially higher for the city residents, the better educated—especially those with high school or college education, and those married to husbands engaged in non-agricultural occupations—those in professional or managerial posts in particular. They are lowest for the non-schooled, the village

residents, and those whose husbands are in agriculture. These differentials persist within each age group, even as within each category of background characteristics the age patterns observed for all women prevail.

Religious differences and the differences by wife's work pattern are difficult to interpret, as they are likely to be influenced by compositional differences involving residence and/or education. Thus, data are presented in Tables 82 and 83, without any effort here to interpret the results.

3.8.10 SUMMARY

1. This section dealt with a wide range of topics from knowledge and use of contraception to lactation and induced abortion. The last topic is included in this report because of its recognized importance in recent years in determining fertility levels in Korea.
2. Knowledge of contraception is widespread in Korea. Ninety-seven per cent of all ever-married women in the present survey reported knowledge of at least one "efficient" method—such as, the pill, the loop, condom, injection, male and female sterilizations, and other female methods like the diaphragm and foam tablets. ("Inefficient" methods include such methods as the rhythm, withdrawal, douche, abstinence, and miscellaneous others.) Compared to 1964 when the first Korean KAP survey reported a level of knowledge of only about 50 per cent, the diffusion of knowledge in the last decade is remarkable.
3. Differentials in Knowledge by background characteristics are small and insignificant in that in nearly all categories of women over 90 per cent report knowledge of at least one method.
4. The best known methods in Korea are the pill (94%), the loop (91%), vasectomy (84%), condom (75%), female sterilization (66%), and rhythm (55%) in that order. All other methods are much less well known, though some under-reporting has to be expected with regard to such methods as the withdrawal, douching, and abstinence.
5. Use of contraception too is quite widespread in Korea today. Fifty-two per cent have tried at least one of the "efficient" methods and an additional 5 per cent an "inefficient" method only.
6. Use is most frequent (about 70%) in the ages 35-44 and parities 3 to 5. There appears to be under-reporting of use by those in the ages 45 and over, judging from the fact that the surveys in the mid-1960's recorded relatively high level of use for these same cohort of women who were then aged about 35-39.
7. Differentials in ever-use follow the usual pattern. Education is the background characteristics that is most closely related to ever-use of contraception. The better educated are more likely to have ever used than the less educated, the distinction being most marked between the non-schooled or primary level education only and those with education beyond the primary level. This pattern holds within each parity.

The city residents are more likely to have used than the town and village residents, although this differential is confined to those with less than 4 children.

Religious differences are small. The slightly higher use among the Christians, both Protestants and Catholics, as compared to the Buddhists and those who profess no religion may be due to their more favourable educational composition and greater urban residence.

The women whose husbands are in professional or managerial occupations tend to have the highest level of ever use, with those in agriculture or unskilled manual jobs, the lowest. There is little consistent differences among the other occupations.

8. Pill has been the most widely used method in Korea (33%), followed by the loop (24%), condom (22%), rhythm (16%), and withdrawal (12%).
9. Current use of contraception was examined for those women who are fecund and exposed to the risk of conception, thus excluding the unmarried, the currently pregnant, and those with reported fecundity impairments other than voluntary sterilization (either vasectomy or female sterilization) for contraceptive purposes. Of the 3,549 "exposed" women, who comprised 71 per cent of the ever-married subject to the individual survey, 46 per cent reported current use of contraception, including sterilization for contraceptive purposes.
10. Current use is associated with both age and family size. It is most frequent for those with two children and those who are in the ages 35-39. It does not necessarily increase much with parity beyond two children. It in fact declines somewhat in the ages 40 and over.
11. Current use is related quite strongly to the sex composition of the family. Korean couples are not likely to be using contraception much unless they have at least two sons. But once they have two sons use becomes quite frequent (60% or more), whether they have only two children, or 3, 4, or 5 or more. Not having a daughter does not deter them from use. In short, the desire for at least two sons still exerts a major influence on Korean fertility behaviour.
12. Differentials in current use of contraception by background characteristics follow very closely the differentials with respect to ever use. Educational differentials are still quite large, suggesting that the convergence in contraceptive behaviour noted in earlier research is far from complete. Occupational differentials too -especially between the professional or managerial workers, on the one hand, with high level of use and the agricultural or manual workers, on the other hand, with low level of use- are still quite large. Wife's work experience, on the other hand, does not seem to be related to current use in any systematic way. The differentials by place of residence and religion follow those observed for ever users. The differential between city and village residents is confined to those with small families as with the ever users, but the slightly higher levels of use by the Christians as compared to the non-Christians persist even among those with large families.
13. The pill and loop are the most popular methods in current use, together comprising half of all use. Condom and rhythm follow in order but are used more by those with small rather than large families (no doubt influenced by age and background characteristics). Fifteen per cent are sterilized with vasectomy twice as popular as tubal ligation. Significantly, couples with fewer than 4 children are as likely to accept sterilization as those with 4 or more children.

About 22 per cent of the couples are relying on "inefficient" methods-mainly rhythm and withdrawal, and their popularity does not seem to vary by family size. There is no indication of a tendency for couples to switch from "inefficient" to "efficient" methods with increase in family size.

14. A comparison with previous surveys in Korea shows that current use of contraception has increased nearly two-fold from 1966 to 1974: from 20 per cent to 37 per cent of currently married women in the ages under 45. The overall rate of current use has not increased much between 1973 and 1974, but there appears to have been an increase in pill use in the urban areas. There is also a sizeable increase in reported use in the ages 30-34, from 38 per cent in 1973 to 45 per cent in 1974.

While current use has increased in both urban and rural areas, the differential has remained fairly constant over the past 5 years. Educational differences too persist, though some convergence is in evidence with a substantial increase in use occurring among those with no schooling in recent years. These changes must be interpreted with some caution, however, because of changes in age composition in the educational categories associated with recent improvements in educational opportunities.

15. The respondents in the survey were classified by "pattern of contraceptive use," which combines in a summary fashion several variables examined separately such as current or past use of contraception and a few new variables such as future intention to use among those who never used so far.

In this section, analysis was restricted to the future intentions of the currently married, fecund never-users. Overall, 60 per cent of them stated an intention for future use, with no variation by current family size. Differentials by background characteristics were similar to those observed for current or ever-users. The proportion intending future use was lowest among the least educated, the rural, and the wives whose husband are in agriculture or unskilled manual occupations. The differences, however, were slight, suggesting the absence of readily identifiable areas of resistance to family planning, assuming intention is uniformly translated into action.

16. An approximate assessment of contraceptive efficacy is obtained by comparing the length of the last closed birth interval and that of the open birth interval between those who ever used contraception in the given intervals and those who did not.

The mean length of the last closed birth interval for those with at least 2 live births, including a current pregnancy, is about 17 per cent longer for those who report ever use of contraception in that interval as compared to those who report no use: 41.4 months vs. 35.5 months. This difference holds roughly in all age groups.

The mean length of the open birth interval for the currently married, fecund women with at least one live birth is 86 per cent longer for those who report ever use of contraception in that interval as compared to those who report no use: 56.6 months vs. 30.7 months. The differences are greater in the ages under 35 and much less in the ages 35 and over, suggesting that there may be selectivity in current use by fecundity status among the older women. In the older ages, the more fecund may find themselves using contraception more often, leaving the less fecund among the non-users, thus showing apparently less contraceptive efficacy than may actually be the case.

In general, it appears that contraceptive efficacy may be greater in terminating childbearing than in spacing. This tentative conclusion is based on the observed greater differential by contraceptive use in length of interval for the open than for the closed birth interval. Such an interpretation, however, ignores any effect lactation or induced abortion may have on the length of these intervals.

17. The role of lactation was briefly examined in relation to the length of the last closed birth interval. The sample was severely restricted in several ways to remove the possible sources of bias due to truncation of observation. Overall, 94 per cent of the specially restricted sample of women reported breastfeeding in the last closed birth interval for an average duration of slightly less than 20 months.

While breastfeeding is still widespread, there is indication that it may be declining somewhat

among the younger women, the better educated, and the city residents.

Breastfeeding is related to length of the last closed birth interval only after at least 6 months of breastfeeding. For the non-contraceptors, the mean length of the birth interval is 24.1 months for those who did not breastfeed at all as compared to 23.0 months for those who breastfed for less than 6 months but rises to 26.7 months for those who breastfed for 6 to 12 months to as long as 35.1 months for those who breastfed for 24 months or longer. The same pattern holds roughly in every age group and for those who ever used contraception in the interval also, with the latter showing gains of about 3 to 4 months in each category of length of breastfeeding over those who never used contraception.

18. Preliminary findings with regard to induced abortion are included in this report because of its importance in Korean fertility behaviour.

Approval of abortion is widespread in both urban and rural areas, with only about 16 per cent disapproving, according to a national sample survey in 1973.

The use of abortion has increased nearly two-fold since 1968 from about 16 per cent of the currently married women in the ages 15-49 in 1968 to about 31 per cent in 1974, but the gain has been greatest between 1968 and 1971, especially among the rural women. The increase since 1971 is evident in every age group but especially in the ages 20-29 and 30-34.

Collectively the women in the present survey reported an average of 0.6 abortion, with 30 per cent reporting at least one abortion and 14 per cent, two or more.

Both ever use of abortion and the mean number of abortions are consistently higher the larger the number of non-current pregnancies the women has had but not so beyond 3 children by number of living children. There is a decline in these figures after 3 children, though generally they are highest in the parities 3 to 5, suggesting that perhaps use of abortion has helped to keep achieved fertility from increasing further.

Of the approximately 23,800 non-current pregnancies reported by these women, 14 per cent were terminated by induced abortion and 5 per cent by stillbirth or miscarriage. These rates are roughly the same as those reported in the 1971 Fertility and Abortion Survey (12 per cent by abortion and 6 per cent by stillbirth or miscarriage). For 1974 and 1971, the proportions of non-current pregnancies ending in live births were, respectively, 81 per cent and 82 per cent.

The rate of termination of non-current pregnancies by induced abortion is highest (at 15 per cent) for those in the ages 25-34 and 35-44. The low rate for those in the ages 45 and over is consistent with the trends in fertility and abortion over the years but some under-reporting must be allowed. The rate of loss due to stillbirths and miscarriages seems certainly to have been under-reported in the older ages.

Resort to abortion is closely associated with use of contraception. Basically, contraceptive users are more likely to have resorted to induced abortion also and the more so, the more recent the use of contraception such as the current users and those who used in the open interval though not using now.

The number of children is associated with abortion use only for the sterilized. Abortion use among them is higher for those with less than 4 children than those with 4 or more, suggesting

that abortion used before sterilization may have helped in keeping their family size relatively small.

The proportion of non-current pregnancies terminated by induced abortion is also higher for the contraceptive users and the more so, the more recent the use. Furthermore, the rate of termination by abortion is substantially higher for those with less than 4 children than those with 4 or more. Abortion appears to have helped in keeping in achieved fertility from increasing further.

Differentials in the use of abortion by background characteristics are similar to those observed for contraceptive users. Both the proportion of abortion users and the proportion of pregnancies terminated by abortion are higher for the better-educated, the city residents, and the non-agricultural workers. The relationship of religion or wife's work experience to use of abortion is difficult to interpret without further, more detailed analysis.

3.9 USE OF CONTRACEPTION AS RELATED TO FERTILITY PREFERENCES

3.9.1 INTRODUCTION

In the previous sections of this chapter, the major topics of family size preferences and contraceptive behaviour were discussed. In this section, the two topics are combined in order to obtain a better understanding of both. The focus of attention is on the issue of consistency, or lack of it, between fertility intentions and contraceptive behaviour, and in particular on the extent to which women who state that they want no more children protect themselves from having more children by contraception.

Even in societies where contraceptive practice has been wide spread for some decades, considerable dissonance between attitudes and behaviour can be expected. There are many reasons for this. Husbands may object to the use of contraception, facilities may be too remote, the available methods may not be suitable, side effects may be feared, or supportive social norms may be lacking. Investigation of the reasons for inconsistency between stated attitudes and reported behaviour lies beyond the scope of this report, but it is of interest to contrast the behaviour of those who want and those who do not want more children and to describe the level of inconsistency in attitudes and behaviour among the various segments of the population.

3.9.2 A COMPARISON OF CONTRACEPTIVE BEHAVIOUR BETWEEN WOMEN WITH DIFFERENT FERTILITY PREFERENCES

In Table 84, which is based on the 4,385 women currently married, "exposed" women in the sample, the pattern of contraceptive use is tabulated against whether total desired family size has already been reached or not. An interesting finding is that women who report that they have already reached or exceeded their desired family size have markedly higher levels of current use than those whose actual size is still less than their desired size. This pattern holds across all age groups except those below age 25. In the youngest ages, current use is least among those whose fertility has already exceeded the desired size, suggesting that low use itself may account for the excess occurring so early in life.

3.9.3 DIFFERENTIALS IN CURRENT USE AMONG WOMEN WHO WANT NO MORE CHILDREN

For investigating the differential, by background characteristics in the level of inconsistency between fertility preference and contraceptive behaviour, the level of current use of efficient methods, including sterilization is examined among the 1,246 women who are exposed and want no more children (Who comprise about 22 per cent of all ever-married women in the sample). Forty-four per cent of the exposed women who want no more children are currently using. Or, more to the point, more than half (56 %) are not currently using an efficient method in spite of the fact that they want no more children and are exposed.

The relevant data on differentials are shown in Table 85. There is generally very little difference across categories of the several background characteristics examined. The only exception is education. The college-educated show the lowest rate of non-use, or conversely the highest rate of use. The differences are minor and inconsistent among the other educational categories, especially when examined within age groups.

Except for the college-educated, in nearly all other categories of women, the majority are not using an efficient contraceptive methods in spite of their exposure and stated desired not to have any more children. Among those under 25, the non-use rate is as high as 77 per cent overall and nearly as high (or even higher) in most categories of background characteristics.

Since the proportion exposed and who want no more children is a function of age, the relative size of the group of women in need of family planning is perhaps better measured by the proportion of all currently married women who do not want any more children but are not currently using an efficient contraceptive method though exposed, as shown in Table 86. There, we see that about a third (32%) of all currently married women in the ages 15-49 fall into this category. The proportion of such women is low among the youngest (13%) and the oldest (17%), as might be expected, and highest in the 35-44 age group (42%), followed by the 25-34 age group (32%). Differentials in this proportion by background characteristics are small. Within each age group, the proportion of women in this category is fairly constant across background characteristics. The exceptions are the high school and college educated in the ages 25-34 and the Catholics in the ages 35-44. The proportions are some what lower for the better educated (26-27%) but substantially higher for the Catholics (50%).

TABLE 85. PERCENTAGE OF EXPOSED WOMEN WANTING NO MORE CHILDREN WHO ARE NOT CURRENTLY USING AN EFFICIENT METHOD OF CONTRACEPTION, BY BACKGROUND CHARACTERISTICS AND AGE

Background characteristics	Age				
	All ages	Less than 25	25-34	35-44	45 and more
All	56	77	57	54	59
Level of education:

Catholic	53	—	(51)	57	*

Source: 1974 KNFS, Table 5.2.4A

These findings suggest that the family planning programme in Korea has a fairly clear-cut target group of substantial size to reach. About a third to two-fifths of all currently married women in the ages 25-44 regardless of background characteristics constitute that target. Further studies are needed to discover the reasons why these women who do not want any more children and exposed are not using any efficient contraceptive methods.

TABLE 86. PERCENTAGE OF ALL CURRENTLY MARRIED WOMEN WHO DO NOT WANT ANY MORE CHILDREN BUT ARE NOT CURRENTLY USING AN EFFICIENT CONTRACEPTIVE METHODS THOUGH EXPOSED, BY BACKGROUND CHARACTERISTICS AND AGE

3.9.4 SUMMARY

1. In this section, we examined the relationship between fertility preferences and contraceptive use, focussing on the inconsistencies that exist for a sizeable number of women.
2. Current contraceptive use is considerably more frequent among those whose actual family size has reached or exceeded their desired size in every age group except for these under 25. In the youngest ages, current use is least for those whose fertility exceeds their desired size, suggesting that low use itself may be responsible for the excess occurring so early in life.
3. More than half (56%) of the exposed women who want no more children (comprising about 23 per cent of all ever-married women in the sample) were not currently using an efficient contraceptive method. Except for the college-educated, among whom more than half are current users, in nearly all other categories of women the majority were not using an efficient method in spite of their exposure and stated desired not to have any more children. These women presumably constitute an important target group for Korea's family planning programme.
4. The relative size of the group of women who might be given special attention in the family planning programme because of their obvious need for family planning is measured by the proportion of all currently married women who state that they do not want any more children but are not currently using an efficient contraceptive method though exposed. About a third of all currently married women in the ages 15-49 fall into this category. By age, there are more of them in the ages 25-34 (33%) and 35-44 (42%) and fewer of them in the ages under 25 (13%) and 45 and over (17%). There is very little difference by background characteristics except for the high school and college-educated in the ages 25-34, among whom the proportions are somewhat lower and the Catholics in the ages 35-44, among whom the proportion is quite high (50%)

3.10 CONCLUDING REMARKS

Certain major themes have emerged from this report, and it is felt appropriate to underline here their significance lest they be lost in the details presented and summarized in the preceding sections.

With the accelerated pace of social and economic modernization in recent years in the Republic of Korea, age at first marriage has risen for both men and women; very few persons are currently marrying before age 20. Increasing educational opportunities for young women, coupled with their greater integration into the labour force of the more modern sector, probably account for this alteration in the timing of marriage. Marriage is still nearly universal for women by age 30, however. Marital dissolution by divorce or separation is uncommon, and remarriage by women, fairly rare.

Fertility of Korean women has declined rapidly over last decade due in part to the spread of birth control practice among all age groups and in both urban and rural areas. Later age at marriage has apparently hastened the tempo of early fertility, but average family size itself has declined since the mid-1960's. The pattern of decline in the age-specific fertility rates shows the effect of the rising age at marriage in the youngest age group and of the diffusion of voluntary control of fertility within marriage in the older age groups—in the ages 35 and over in particular. In spite of the substantial decline in every sector, however, significant urban-rural differentials in fertility persist, as do those by education and husband's occupation.

Substantial decline in mortality was achieved in the early years following the Korean War, coinciding with rapid urbanization and improvement in health care facilities that took place throughout the country. Infant mortality, often viewed as an indicator of the health status of a population, declined by at least 20 points (per 1,000 live births) in the decade preceding the survey. Further decline in mortality may be expected with continued improvement in health care programmes and facilities and further rise in standard of living of the population as a whole.

The traditional large family size preference in Korea is rapidly becoming a thing of the past. Women under 30, who reached maturity during the years of intensive family planning programme activities and whose fertility behaviour is of greatest consequence for future rate of population growth, express a desire to have slightly less than three children on the average. Better education and urban residence are associated with smaller family size norms; the on-going process of social modernization in Korea may thus be expected to facilitate the trend toward fewer desired number of children. A marked preference for sons continues to exist, however, and is likely to exert an upward pressure on actual family size during the process of family formation.

Knowledge of contraception is nearly universal throughout the various segments of the population and use is quite widespread, as the great majority of currently married women state a desire for no more children. There are still significant differentials in contraceptive practice, however, by such background characteristics as place of residence, education, and husband's occupation. Induced abortion too continues to play an important role in the determination of fertility levels in Korea. It appears that abortion is used by many women not necessarily as an alternative to contraception but in a somewhat complementary fashion. While sterilization is still not widespread, its potential place in Korea's family planning programme is suggested in the finding that nearly one-fourth of the women as young as 20-24 and over one-half of those in the ages 25-29 state a desire for no more children. Their acceptance of sterilization could have a substantial demographic impact.

There does not seem to be any particular segment of the population strongly resistant to contraception, but there is a sizeable group of women in nearly all categories of background characteristics whose attitude about family size preference and contraceptive behaviour are conspicuously inconsistent. These are the women who, though professing no desire for more children and exposed to risk of further childbearing, are not using an efficient contraceptive method. This group constitutes about one-third of all currently married women. These results, together with the finding that about 70 per cent of all currently married women desire no more children, should help define an urgent task for the family planning programme: to enlist these women to take up efficient methods and to help them sustain their use in an effective manner to avoid unwanted childbearing.

It should be obvious from the above remarks, and indeed from the entire discussion in Chapter 3, that there is ample scope for further analysis of the data. Examination of the fundamental topic of fertility has been tentative at best. It is expected that more definitive estimates of current fertility, for example, would be made after the data are evaluated for their quality and adjustments made as needed. It is also expected that the application of more advanced analytical techniques will clarify the complex interaction among fertility, education, and residence and allow a fuller introduction into the explanatory framework of such variables as the woman's pattern of work, which may prove to have an important bearing on fertility behaviour. Further, it should be noted that a considerable body of data concerning contraceptive behavior, lactation, and induced abortion have not yet been fully exploited. Detailed analysis of these data should permit a broader appraisal of the national family planning programme in Korea than has ever been attempted.

II.6.F	The mean number of children ever born, still alive, and deceased, by current age of women and type of house, for all ever-married women aged 10-49 in the household schedule.	T51
II.6.G	The mean number of children ever born, still alive, and deceased, by current age of women and farm status, for all ever-married women aged 10-49 in the household schedule.	T55
II.6.H	The mean number of children ever born, still alive, and deceased, by current age of women and number of modern objects, for all ever-married women aged 10-49 in the household schedule.	T58
II.6.I	The mean number of children ever born, still alive, and deceased, by current age of women and number of rooms, for all ever-married women aged 10-49 in the household schedule.	T64
II.7.A	The total number of children ever born, according to current age of women and education of women, for all ever-married women in the household schedule.	T68
II.7.B	The total number of children ever born, according to current age of women and type of place of residence, for all ever-married women in the household schedule.	T70
II.7.C	The total number of children ever born, according to current age of women and current marital status for all ever-married women in the household schedule.	T72

Table Number		
II.7.D	The total number of children ever born, according to current age of women and type of house, for all ever-married women on the household schedule.	T73
II.7.E	The total number of children ever born, according to current age of women and number of modern objects, for all ever-married women in the household schedule.	T75
II.7.F	The total number of children ever born, according to current age of women and number of rooms, for all ever-married women in the household schedule.	T78
II.8.A	Of all ever-married women in the household schedule who have had at least one live birth, the percentage distribution of time elapsed since that birth (first cell entry) and the proportion of those children who are still living by education of women.	T80
II.8.B	Of all ever-married women on the household schedule who have had at least one live birth, the percentage distribution of time elapsed since that birth (first cell entry) and the proportion of those children who are still living by type of residence.	T86
II.8.C	Of all ever-married women in the household schedule who have had at least one live birth, the percentage distribution of time elapsed since that birth (first cell entry) and the proportion of those children who are still living by number of rooms.	T94
II.8.D	Of all ever-married women in the household schedule who have had at least one live birth, the percentage distribution of time elapsed since that birth (first cell entry) and the proportion of those children who are still living by number of modern objects.	T102
II.8.E	Of all ever-married women in the household schedule who have had at least one live birth, the percentage distribution of time elapsed since that birth (first cell entry) and the proportion of those children who are still living by education of husband.	T113
II.9.A	Of all ever-married women in the household schedule who had a live birth during the 24 months preceding the survey, the percentage distribution of time elapsed since that birth by education of women.	T120

76

Table Number		
I.9.B	Of all ever-married women in the household schedule who had a live birth during the 24 months preceding the survey, the percentage distribution of time elapsed since that birth by type of place of residence.	T126
I.9.C	Of all ever-married women in the household schedule who had a live birth during the 24 months preceding the survey, the percentage distribution of time elapsed since that birth by number of rooms.	T133
I.9.D	Of all ever-married women in the household schedule who had a live birth during the 24 months preceding the survey, the percentage distribution of time elapsed since that birth by number of modern objects.	T139
I.9.E	Of all ever-married women in the household schedule who had a live birth during the 24 months preceding the survey, the percentage distribution of time elapsed since that birth by education of husband.	T149
I.10.A	Of all currently married women aged 10-49 in the household schedule, the percentage having a live birth in the past one year. Women classified by age, age of husband, and education of women.	T155
I.10.B	Of all currently married women aged 10-49 in the household schedule, the percentage having a live birth in the past one year. Women classified by age, age of husband, and type of place of residence.	T158
I.10.C	Of all currently married women aged 10-49 in the household schedule, the percentage having a live birth in the past one year. Women classified by age, age of husband, and number of rooms.	T162
I.10.D	Of all currently married women aged 10-49 in the household schedule, the percentage having a live birth in the past one year. Women classified by age, age of husband, and number of modern objects.	T165

Table Number		
I.10.E	Of all currently married women aged 10-49 in the household schedule, the percentage having a live birth in the past one year. Women classified by age, age of husband, and education of husband.	T170
I.11.A	Of all currently married women aged 10-49 in the household schedule, the percentage having a live birth in the past one year (first entry) and the percentage not stating the date of last live birth. Women classified by age, number of children ever born, and education of women.	T174
I.11.B	Of all currently married women aged 10-49 in the household schedule, the percentage having a live birth in past one year (first entry) and the percentage not stating the date of last live birth. Women classified by age, number of children ever born, and type of residence.	T180
I.11.C	Of all currently married women aged 10-49 in the household schedule, the percentage having a live birth in the past year (first entry) and the percentage not stating the date of last live birth. Women classified by age, number of children ever born, and number of rooms.	T188
I.11.D	Of all currently married women aged 10-49 in the household schedule, the percentage having a live birth in the past year (first entry) and the percentage not stating the date of last live birth. Women classified by age, number of children ever born, and number of modern objects.	T195
I.11.E	Of all currently married women aged 10-49 in the household schedule, the percentage having a live birth in the past year (first entry) and the percentage not stating the date of last live birth. Women classified by age, number of children ever born, and education of husband.	T206

B. INDIVIDUAL SURVEY TABLES

Table B1. NUPTIALITY AND EXPOSURE TO CHILDBEARING
Number

1.1.1 Distribution of all ever-married women according to age at first marriage - by current age. T213

1.1.2 Distribution of all ever-married women according to age at first marriage in single years - by calendar year of birth. T214

1.1.3A Mean age at first marriage of those women who first married before age 25 - by current age and level of education. T218

1.1.3B Mean age at first marriage of those women who first married before age 25 - by current age and childhood type of place. T218

1.1.3C Mean age at first marriage of those women who first married before age 25 - by current age and religion. T219

1.1.3D Mean age at first marriage of those women who first married before age 25 - by current age and husband's occupation. T219

1.1.3E Mean age at first marriage of those women who first married before age 25 - by current age and work status. T220

1.1.3F Mean age at first marriage of those women who first married before age 25 - by current age and duration of work. T220

1.2.1 Percent distribution of all ever-married women according to status of first marriage - by years since first marriage. T221

1.2.2A Percentage of all ever-married women whose first marriage was dissolved - by years since first marriage and level of education. T222

1.2.2B Percentage of all ever-married women whose first marriage was dissolved - by years since first marriage and type of place of residence. T223

1.2.2C Percentage of all ever-married women whose first marriage was dissolved - by years since first marriage and religion. T223

Table
Number

1.3.1 Percent distribution of all ever-married women according to the number of times married - by years since first marriage and age at first marriage. T224

1.3.2A Of all ever-married women whose first marriage was dissolved, the percentage who re-married - by years since first marriage and level of education. T225

1.3.2B Of all ever-married women whose first marriage was dissolved, the percentage who re-married - by years since first marriage and type of place. T226

1.3.2C Of all ever-married women whose first marriage was dissolved, the percentage who re-married - by years since first marriage and religion. T226

1.5.1 Percentage of ever-married women in each marital status, according to years since first marriage and age at first marriage. T227

1.5.2A Percentage of ever-married women who are currently married - by years since first marriage, age at first marriage and level of education. T228

1.5.2B Percentage of ever-married women who are currently married - by year since first marriage, age at first marriage and type of place. T229

1.5.2C Percentage of ever-married women who are currently married - by years since first marriage, age at first marriage and religion. T230

1.6.1 Percent distribution of all ever-married women according to exposure status - by years since first marriage and age at first marriage. T231

1.6.2 Percent distribution of all ever-married women according to exposure status - by number of living children and age. T232

1.6.3A Percent distribution of all ever-married women according to exposure status - by level of education and current age. T233

1.6.3B Percent distribution of all ever-married women according to exposure status - by type of place of residence and current age. T234

Table Number	
1.6.3C	Percent distribution of all ever-married women according to exposure status - by religio. and current age. T235
1.6.3D	Percent distribution of all ever-married women according to exposure status - by husband's occupation and current age. T236

B 2. FERTILITY

2.1.1	Percent distribution of women who first married at least five years ago according to the interval between first marriage and first birth - by age at first marriage and years since first marriage. T238
2.1.2A	Mean number of children born before or within first five years of marriage - by level of education, age at first marriage and years since first marriage, confined to women who first married at least five years ago. T239
2.1.2B	Mean number of children born before or within first five years of marriage - by type of place of residence, age at first marriage and years since first marriage, confined to women who first married at least five years ago. T241
2.1.2C	Mean number of children born before or within first five years of marriage - by religion, age at first marriage and years since first marriage, confined to women who first married at least five years ago. T242
2.1.2D	Mean number of children born before or within first five years of marriage - by husband's occupation, age at first marriage and years since first marriage, confined to women who first married at least five years ago. T244
2.1.2E	Mean number of children born before or within first five years of marriage - by occupation before first marriage, age at first marriage and years since first marriage, confined to women who first married at least five years ago. T246
2.1.2F	Mean number of children born before or within first five years of marriage - by work status before first marriage, age at first marriage and years since first marriage, confined to women who first married at least five years ago. T248

Table Number	
2.1.2G	Mean number of children born before or within first five years of marriage - by worked in first interval, age at first marriage and years since first marriage, confined to women who first married at least five years ago with one or more live births. T249
2.2.1A	Percentage distribution of all ever-married women according to the number of children ever born - by current age. T250
2.2.1B	Percentage distribution of currently married women according to the number of children ever born - by current age. T250
2.2.2A	Percentage distribution of all ever-married women according to the number of children ever born - by years since first marriage. T250
2.2.2B	Per centage distribution of currently married women according to the number of children ever born - by years since first marriage. T250
2.2.3A	Mean number of children ever born to all ever-married women - by age at first marriage and years since first marriage. T251
2.2.3B	Mean number of children ever born to all currently married women - by age at first marriage and years since first marriage. T251
2.2.4A	Mean number of children ever born to all ever-married women - by age at first marriage and current age. T252
2.2.4B	Mean number of children ever born to all currently married women - by age at first marriage and current age. T252
2.2.5A	Percent distribution of all ever-married women according to the number of children ever born - by level of education and years since first marriage. T253
2.2.5B	Percent distribution of all ever-married women according to the number of children ever born - by type of place of residence and years since first marriage. T255
2.2.5C	Percent distribution of all ever-married women according to the number of children ever born - by religion and years since first marriage. T256

Table Number		
2.2.5D	Percent distribution of all ever-married women according to the number of children ever born - by husband's occupation and years since first marriage.	T258
2.2.5E	Percent distribution of all ever-married women according to the number of children ever born - by pattern of work and years since first marriage.	T260
2.2.6A	Mean number of children ever born to all ever-married women - by level of education, age at first marriage and current age.	T262
2.2.6B	Mean number of children ever born to all ever-married women - by type of place of residence, age at first marriage and current age.	T264
2.2.6C	Mean number of children ever born to all ever-married women by religion, age at first marriage and current age.	T266
2.2.6D	Mean number of children ever born to all ever-married women - by husband's occupation, age at first marriage and current age.	T268
2.2.6E	Mean number of children ever born to all ever-married women - by pattern of work, age at first marriage and current age.	T270
2.2.7A	Mean number of children ever born to all ever married women - by level of education, type of place of residence and years since first marriage.	T272
2.2.7B	Mean number of children ever born to all ever-married women - by level of education, religion and years since first marriage.	T273
2.2.7C	Mean number of children ever born to all ever-married women - by level of education, husband's occupation and years since first marriage.	T275
2.2.7D	Mean number of children ever born to all ever-married women - by level of education, number of modern objects owned and years since first marriage.	T277
2.2.7E	Mean number of children ever born to all ever-married women - by level of education, pattern of work, and years since first marriage.	T279

Table Number		
2.2.7F	Mean number of children ever born to all ever-married women - by level of education, literacy and years since first marriage.	T281
2.2.7G	Mean number of children ever born to all ever-married women - by level of education, husband's education and years since first marriage.	T282
2.2.7H	Mean number of children ever born to all ever-married women - by level of education, most recent occupation and years since first marriage.	T284
2.2.7J	Mean number of children ever born to all ever-married women - by type of place of residence, religion and years since first marriage.	T286
2.2.7K	Mean number of children ever born to all ever-married women - by type of place of residence, husband's occupation and years since first marriage.	T287
2.2.7L	Mean number of children ever born to all ever-married women - by type of place of residence, pattern of work and years since first marriage.	T288
2.2.7M	Mean number of children ever born to all ever-married women - by type of place of residence, childhood type of place of residence and years since first marriage.	T289
2.2.7N	Mean number of children ever born to all ever-married women - by religion, husband's occupation and years since first marriage.	T290
2.2.7O	Mean number of children ever born to all ever-married women - by religion, pattern of work and years since first marriage.	T291
2.2.7P	Mean number of children ever born to all ever-married women - by husband's occupation, number of modern objects owned and years since first marriage.	T292
2.2.7Q	Mean number of children ever born to all ever-married women by husband's occupation, pattern of work and years since first marriage.	T294

Table
Number

2.3.1A	Percentage distribution of all ever-married women according to the number of living children - by current age.	T 296
2.3.1B	Percentage distribution of currently married women according to the number of living children - by current age.	T 296
2.3.2A	Percentage distribution of all ever-married women according to the number of living children - by years since first marriage.	T 296
2.3.2B	Percentage distribution of currently married women according to the number of living children - by years since first marriage.	T 296
2.3.3	Percent distribution of all ever-married women according to the number of living children - by number of children ever born and current age.	T 297
2.3.4	For all ever-married women, the mean number of children ever born, still alive and deceased - by current age in single years.	T 298
2.4.1	Mean number of children born in past 5 years to women who have been continuously in married state for the past five years - by current age and number of living children at beginning of 5 years period.	T 299
2.4.2	Mean number of children born in past 5 years to women who have been continuously in married state for the past 5 years - by current age and age at first marriage.	T 299
2.4.3A	Mean number of children born in past 5 years to women who have been continuously in married state for the past 5 years - by current age and level of education.	T 300
2.4.3B	Mean number of children born in past 5 years to women who have been continuously in married state for the past 5 years - by current age and type of place of residence.	T 300
2.4.3C	Mean number of children born in past 5 years to women who have been continuously in married state for the past 5 years - by current age and religion.	T 301
2.4.3D	Mean number of children born in past 5 years to women who have been continuously in married state for the past 5 years - by current age and husband's occupation.	T 301

Table
Number

2.4.3E	Mean number of children born in past 5 years to women who have been continuously in married state for the past 5 years - by current age and pattern of work.	T 302
2.4.3F	Mean number of children born in past 5 years to women who have been continuously in married state for the past 5 years - by current age and years since most recent work.	T 302
2.4.4	Percentage male, of children born in the past five years to women who have been continuously in the married state for the past five years - by current age and age at first marriage.	T 303
2.4.5	Percentage of currently married women reporting a current pregnancy - by current age and number of living children.	T 304
2.4.6	Percentage of currently married women reporting a current pregnancy - by current age and age at first marriage.	T 304
2.4.7A	Mean number of children born in past 5 years to women who have been continuously in married state for the past 5 years - by years since first marriage and level of education.	T 305
2.4.7B	Mean number of children born in past 5 years to women who have been continuously in married state for the past 5 years - by years since first marriage and type of place of residence.	T 305
2.4.7C	Mean number of children born in past 5 years to women who have been continuously in married state for the past 5 years - by years since first marriage and religion.	T 306
2.4.7D	Mean number of children born in past 5 years to women who have been continuously in married state for the past 5 years - by years since first marriage and husband's occupation.	T 306

B 3. SURVIVORSHIP OF CHILDREN

3.1.1	Percentage of currently married "Fecund" women who want no more children - by number of living children (including any current pregnancy) and current age.	T 307
-------	---	-------

Table Number		
3.1.2	Percentage of currently married "Fecund" women who want no more children - by number of living children (including any current pregnancy) and years since first marriage.	T307
3.1.3A	Percentage of currently married "Fecund" women who want no children - by number of living children (including any current pregnancy), level of education and current age.	T308
3.1.3B	Percentage of currently married "Fecund" women who want no more children - by number of living children (including any current pregnancy) and type of place and current age.	T310
3.1.3C	Percentage of currently married "Fecund" women who want no more children - by number of living children (including any current pregnancy), religion and current age.	T311
3.1.3D	Percentage of currently married "Fecund" women who want no more children - by number of living children (including any current pregnancy), husband's occupation and current age.	T313
3.1.3E	Percentage of currently married "Fecund" women who want no more children - by number of living children (including any current pregnancy), patterns of work and current age.	T316
3.1.4	Percentage of currently married women with at least one live birth (or current pregnancy) who did not want last birth (or current pregnancy) - by number of living children (including any pregnancy) and current age.	T318
3.1.5	Percentage of currently married women with at least one live birth (or current pregnancy) who did not want last birth (or current pregnancy) - by number of living children (including any pregnancy) and years since first marriage.	T318
3.2.1	Percent distribution of currently married "Fecund" women according to the number of additional children wanted - by current age.	T319
3.2.2	Percent distribution of current married "Fecund" women according to the number of additional children wanted - by years since first marriage.	T319

Table Number		
3.2.3	Mean additional number of children wanted by currently married "Fecund" women - by number of living children (including any current pregnancy) and current age.	T320
3.2.4	Mean additional number of children wanted by currently married "Fecund" women - by number of living children (including any current pregnancy) and years since first marriage.	T320
3.2.5A	Mean additional number of children wanted by currently married "Fecund" women - by number of living children (including any current pregnancy) and current age and level of education.	T321
3.2.5B	Mean additional number of children wanted by currently married "Fecund" women - by number of living children (including any current pregnancy), current age and type of place.	T324
3.2.5C	Mean additional number of children wanted by currently married "Fecund" women - by number of living children (including any current pregnancy), current age and religion.	T325
3.2.5D	Mean additional number of children wanted by currently married "Fecund" women - by number of living children (including any current pregnancy), current age and husband's occupation.	T327
3.2.5E	Mean additional number of children wanted by currently married "Fecund" women - by number of living children (including any current pregnancy), current age and pattern of work.	T330
3.3.1A	Percent distribution of all ever-married women according to the total number of children desired - by current age.	T332
3.3.1B	Percent distribution of currently married women according to the total number of children desired - by current age.	T332
3.3.2A	Percent distribution of all ever-married women according to the total number of children desired - by years since first marriage.	T333
3.3.2B	Percent distribution of currently married women according to the total number of children desired - by years since first marriage.	T333
3.3.3A	Percent distribution of all ever-married women according to the total number of children desired - by number of living children.	T334

Table Number		
3.3.3B	Percent distribution of currently married women according to the total number of children desired - by number of living children	T334
3.3.4A	Mean total number of children desired by currently married women - by number of living children (including any current pregnancy) and current age.	T335
3.3.4B	Mean total number of children desired by all ever-married women - by number of living children (including any current pregnancy) and current age.	T335
3.3.5A	Mean total number of children desired by currently married women - by number of living children (including any current pregnancy) and years since first marriage.	T336
3.3.5B	Mean total number of children desired by all ever-married women - by number of living children (including any current pregnancy) and years since first marriage.	T336
3.3.6	Mean total number of children desired by currently married women - by number of living children (including any current pregnancy), years since first marriage and age at first marriage.	T337
3.3.7A	Mean total number of children desired by currently married women - by number of living children (including any current pregnancy), level of education and current age.	T340
3.3.7B	Mean total number of children desired by currently married women - by number of living children (including any current pregnancy), type of place of residence and current age.	T342
3.3.7C	Mean total number of children desired by currently married women - by number of living children (including any current pregnancy), religion and current age.	T343
3.3.7D	Mean total number of children desired by currently married women - by number of living children (including any current pregnancy), husband's occupation and current age.	T345
3.3.7E	Mean total number of children desired by currently married women - by number of living children (including any current pregnancy), pattern of work and current age.	T348

Table Number		
3.4.1	Percentage of currently married fecund, non-pregnant women who want no more children - by number of living sons, number of living daughters and current age.	T351
3.4.3A	Of currently married fecund, non-pregnant women who want a future birth, the percentage preferring a boy - by number of living sons, number of living daughters and current age.	T353
3.4.3B	Of currently married fecund, non-pregnant women who want a future birth, the percentage preferring a girl - by number of living sons, number of living daughters and current age.	T355
3.4.5	Mean additional number of children wanted by currently married fecund, non-pregnant women - by number of living sons, number of living daughters and current age.	T357
3.4.6A	Mean total number of children desired by currently married, fecund non-pregnant women - by number of living sons, number of living daughters and current age.	T359
3.4.6B	Mean total number of children desired by ever-married, fecund non-pregnant women - by number of living sons, number of living daughters and current age.	T361

B 4. KNOWLEDGE AND USE OF CONTRACEPTION

4.1.1	Percent distribution of women according to length of breastfeeding in the last closed interval - by current age and age at first marriage, confined to women with at least two live birth (including any current pregnancy).	T363
4.1.2	Percent distribution of women according to length of breastfeeding in the last closed interval - by number of children ever - born (including any current pregnancy), confined to women with at least two live births (including any current pregnancy).	T363
4.1.3	Percent distribution of women according to length of breastfeeding in months in the last closed interval - by current age and age at first marriage, confined to women with at least two live births (including any current pregnancy), whose last closed interval exceeds 32 months and whose child survived at least 24 months.	T364

Table
Number

4.1.4	Percent distribution of women according to length of breastfeeding in months in the last closed interval - by number of children ever - born (including any current pregnancy), confined to women with at least two live births (including any current pregnancy), whose last closed interval exceeds 32 months and whose child survived at least 24 months.	T364
4.1.5A	Percent distribution of women according to length of breastfeeding in months in the last closed interval - by number of children ever - born (including any current pregnancy) and level of education, confined to women with at least two live births (including any current pregnancy), whose last closed interval exceeds 32 months and whose child survived at least 24 months.	T365
4.1.5B	Percent distribution of women according to length of breastfeeding in months in the last closed interval - by number of children ever - born (including any current pregnancy) and type of place, confined to women with at least two live births (including any current pregnancy), whose last closed interval exceeds 32 months and whose child survived at least 24 months.	T366
4.1.5C	Percent distribution of women according to length of breastfeeding in months in the last closed interval - by number of children ever born (including any current pregnancy), and religion, confined to women with at least two live births (including any current pregnancy), whose last closed interval exceeds 32 months and whose child survived at least 24 months.....	T367
4.1.5D	Percent distribution of women according to length of breastfeeding in months in the last closed interval - by number of children ever born (including any current pregnancy) and husband's occupation, confined to women with at least two live births (including any current pregnancy), whose last closed interval exceeds 32 months and whose child survived at least 24 months.....	T368
4.1.5E	Percent distribution of women according to length of breastfeeding in months in the last closed interval - by number of children ever born (including any current pregnancy) and pattern of work, confined to women with at least two live births (including any current pregnancy), whose last closed interval exceeds 32 months and whose child survived at least 24 months	T369

Table
Number

4.1.6	Mean length in months of the last closed interval - by whether the women has ever used contraception in the last closed interval, number of months breastfeeding during that interval and current age, confined to women with at least two live births (including current pregnancy) whose last closed interval did not exceed five years.....	T370
4.2.1A	Percentage of all ever-married women who have heard of specified contraceptive methods, including sterilization - by current age and number of living children.....	T371
4.2.1B	Percentage of currently married "fecund" women who have heard of specified contraceptive methods, including sterilization - by current age and number of living children	T372
4.2.2A	Percentage of all ever-married women who have heard of no contraceptive methods, including sterilization - by number of living children, level of education and current age	T373
4.2.2.B	Percentage of all ever-married women who have heard of no contraceptive methods, including sterilization - by number of living children, type of place of residence and current age.....	T373
4.2.2C	Percentage of all ever-married women who have heard of no contraceptive methods, including sterilization - by number of living children, religion and current age.....	T373
4.2.3A	Percentage of all ever-married women who know no contraceptive methods, including sterilization - by number of living children, level of education and current age	T374
4.2.3B	Percentage of all ever-married women who know no contraceptive methods, including sterilization - by number of living children, type of place of residence and current age.....	T378
4.2.3C	Percentage of all ever-married women who know no contraceptive methods, including sterilization - by number of living children, religion and current age	T380
4.3.1A	Percentage of all ever-married women who ever used specified contraceptive methods, including sterilization - by current age and number of living children.....	T384

Table Number		
4.3.1B	Percentage of currently married "Fecund" women who ever used specified contraceptive methods, including sterilization - by current age and number of living children.....	T385
4.3.2A	Percentage of all ever-married women who ever used any contraceptive method, including sterilization - by number of living children, level of education and current age	T386
4.3.2B	Percentage of all ever-married women who ever used any contraceptive method, including sterilization - by number of living children, type of place of residence and current age	T388
4.3.2C	Percentage of all ever-married women who ever used any contraceptive method, including sterilization - by number of living children, religion and current age	T389
4.3.2D	Percentage of all ever-married women who ever used any contraceptive method, including sterilization - by number of living children, husband's occupation and current age.....	T391
4.3.2E	Percentage of all ever-married women who ever used any contraceptive method, including sterilization - by number of living children, pattern of work and current age	T394
4.4.1	Percentage of "Exposed" women who are currently using a specified contraceptive method, including sterilization - by number of living children and current age	T396
4.4.2	Percentage of "Exposed" women who are currently using contraception, including sterilization - by number of living children and current age.	T397
4.4.3	Percentage of "Exposed" women who are currently using contraception, including sterilization - by number of living daughters, number of living sons and current age	T398
4.4.4	Percentage of "Exposed" women who are currently using contraception, including sterilization - by number of living daughters, number of living sons and years since first marriage	T400
4.4.5A	Percentage of "Exposed" women who are currently using contraception, including sterilization - by number of living children, level of education and current age	T402

Table Number		
4.4.5B	Percentage of "Exposed" women who are currently using contraception, including sterilization - by number of living children, type of place of residence and current age	T404
4.4.5C	Percentage of "Exposed" women who are currently using contraception, including sterilization - by number of living children, religion and current age	T405
4.4.5D	Percentage of "Exposed" women who are currently using contraception, including sterilization - by number of living children, husband's occupation and current age	T407
4.4.5E	Percentage of "Exposed" women who are currently using contraception, including sterilization - by number of living children, pattern of work and current age	T409
4.4.5F	Percentage of "Exposed" women who are currently using contraception, including sterilization - by number of living children, years since most recent work and current age.....	T411
4.5.1	Percent distribution of all ever-married women according to pattern of contraceptive use - by current age	T413
4.5.2	Percent distribution of all ever-married women according to pattern of contraceptive use - by years since first marriage and at first marriage.....	T414
4.5.3	Percent distribution of all ever-married women according to pattern of contraceptive use - by number of living children	T415
4.5.4	Percent distribution of all ever-married women according to pattern of contraceptive use - by exposure status and current age	T416
4.5.5A	Percent distribution of all ever-married women according to pattern of contraceptive use - by level of education and current age.....	T417
4.5.5B	Percent distribution of all ever-married women according to pattern of contraceptive use - by type of place of residence and current age	T418
4.5.5C	Percent distribution of all ever-married women according to pattern of contraceptive use - by religion and current age	T419

Table Number		
4.5.5D	Percent distribution of all ever-married women according to pattern of contraceptive use - by husband's occupation and current age.....	T 420
4.5.5E	Percent distribution of all ever-married women according to pattern of contraceptive use - by pattern of work and current age.....	T 422
4.5.6A	Percent distribution of all ever-married women according to pattern of contraceptive use - by level of education and number of living children.....	T 423
4.5.6B	Percent distribution of all ever-married women according to pattern of contraceptive use - by type of place of residence and number of living children.....	T 424
4.5.6C	Percent distribution of all ever-married women according to pattern of contraceptive use - by religion and number of living children.....	T 425
4.5.6D	Percent distribution of all ever-married women according to pattern of contraceptive use - by husband's occupation and number of living children.....	T 426
4.5.6E	Percent distribution of all ever-married women according to pattern of contraceptive use - by pattern of work and number of living children.....	T 427
4.6.1	Percent distribution of women according to the length of the open interval - by contraceptive use (excluding sterilization) in the open interval and current age, confined to "Exposed" women with one or more living births.....	T 428
4.6.2	Percent distribution of women according to the length of the closed interval - by contraceptive use (excluding sterilization) in the closed interval and current age, confined to women with at least 2 live births (including any current pregnancy).....	T 429
4.7.1	Percent distribution of all ever-married women according to number of induced abortions - by current age.....	T 430
4.7.2	Percent distribution of all ever-married women according to number of induced abortions - by number of living children.....	T 430
4.7.3	Percent distribution of all ever-married women according to number of induced abortions - by total number of completed pregnancies.....	T 431

Table Number		
4.7.4	Percent distribution of all ever-married women according to number of spontaneous abortion - by current age.....	T 431
4.7.5	Percent distribution of all ever-married women according to number of spontaneous abortions - by number of living children.....	T 432
4.7.6	Percent distribution of all ever-married women according to number of spontaneous abortions - by total number of completed pregnancies.....	T 432
4.8.1A	Percentage of all ever-married women who have had an induced abortions - by number of living children, level of education and current age.....	T 433
4.8.1B	Percentage of all ever-married women who have had an induced abortions - by number of living children, type of place of residence and current age.....	T 436
4.8.1C	Percentage of all ever-married women who have had an induced abortions - by number of living children, religion and current age.....	T 438
4.8.1D	Percentage of all ever-married women who have had an induced abortions - by number of living children, husband's occupation and current age.....	T 440
4.8.1E	Percentage of all ever-married women who have had an induced abortions - by number of living children, pattern of work and current age.....	T 443
4.8.1F	Percentage of all ever-married women who have had an induced abortions - by number of living children, pattern of contraceptive use and current age.....	T 446
4.8.2A	Percentage of all ever-married women who have had spontaneous abortions - by number of living children, level of education and current age.....	T 451
4.8.2B	Percentage of all ever-married women who have had spontaneous abortions - by number of living children, type of place of residence and current age.....	T 453

Table Number		
4.8.2C	Percentage of all ever-married women who have had spontaneous abortions - by number of living children, religion and current age	T455
4.8.2D	Percentage of all ever-married women who have had spontaneous abortions - by number of living children, husband's occupation and current age	T457
4.8.2E	Percentage of all ever-married women who have had spontaneous abortions - by number of living children, pattern of work and current age	T460
4.8.2F	Percentage of all ever-married women who have had spontaneous abortions - by number of living children, pattern of contraceptive use and current age	T463
4.8.3A	Mean number of induced abortions experienced by all ever-married women - by number of living children, level of education and current age	T468
4.8.3B	Mean number of induced abortions experienced by all ever-married women - by number of living children, type of place of residence and current age	T470
4.8.3C	Mean number of induced abortions experienced by all ever-married women - by number of living children, religion, and current age	T472
4.8.3D	Mean number of induced abortions experienced by all ever-married women - by number of living children, husband's occupation and current age	T474
4.8.3E	Mean number of induced abortions experienced by all ever-married women - by number of living children, pattern of work and current age	T477
4.8.3F	Mean number of induced abortions experienced by all ever-married women - by number of living children, pattern of contraceptive use and current age	T480
4.8.4A	Mean number of spontaneous abortions experienced by all ever-married women - by number of living children, level of education and current age	T485

Table Number		
4.8.4B	Mean number of spontaneous abortions experienced by all ever-married women - by number of living children, type of place of residence and current age	T487
4.8.4C	Mean number of spontaneous abortions experienced by all ever-married women - by number of living children, religion and current age	T489
4.8.4D	Mean number of spontaneous abortions experienced by all ever-married women - by number of living children, husband's occupation and current age	T491
4.8.4E	Mean number of spontaneous abortions experienced by all ever-married women - by number of living children, pattern of work and current age	T494
4.8.4F	Mean number of spontaneous abortions experienced by all ever-married women - by number of living children, pattern of contraceptive use and current age	T497
4.8.5A	Percentage of all completed pregnancies that ended in induced abortions - by number of living children, level of education and current age	T502
4.8.5B	Percentage of all completed pregnancies that ended in induced abortions - by number of living children, type of place of residence and current age	T507
4.8.5C	Percentage of all completed pregnancies that ended in induced abortions - by number of living children, religion and current age	T509
4.8.5D	Percentage of all completed pregnancies that ended in induced abortions - by number of living children, husband's occupation and current age	T511
4.8.5E	Percentage of all completed pregnancies that ended in induced abortions - by number of living children, pattern of work and current age	T516
4.8.5F	Percentage of all completed pregnancies that ended in induced abortions - by number of living children, pattern of contraceptive use and current age	T521

Table Number	
4.8.6A	Percentage of all completed pregnancies that ended in spontaneous abortions-by number of living children, level of education and current age T526
4.8.6B	Percentage of all completed pregnancies that ended in spontaneous abortions - by number of living children, type of place of residence and current age T529
4.8.6C	Percentage of all completed pregnancies that ended in spontaneous abortions - by number of living children, religion and current age T531
4.8.6D	Percentage of all completed pregnancies that ended in spontaneous abortions - by number of living children, husband's occupation and current age T534
4.8.6E	Percentage of all completed pregnancies that ended in spontaneous abortions - by number of living children, pattern of work and current age T539
4.8.6F	Percentage of all completed pregnancies that ended in spontaneous abortions - by number of living children, pattern of contraceptive use and current age T544
4.8.7	Percentage of all ever-married women who have had an induced abortion - by age and background variable T549
4.8.8	Percentage of currently married women who have had an induced, abortion - by age and background variable T550

B 5. PREFERENCES FOR NUMBER AND SEX OF CHILDREN

5.2.1	Percent distribution of "Exposed" women according to current use of specified contraceptive methods (including sterilization) - by number of living children and desire for more children T551
5.2.2	Percentage of "Exposed" women wanting no more children who are not currently using an efficient method of contraception (including sterilization) - by age at first marriage and years since first marriage T552

Table Number	
5.2.3	Percentage of "Exposed" women wanting no more children who are not currently using an efficient method of contraception (including sterilization) - by current age and number of living children T552
5.2.4A	Percentage of "Exposed" women wanting no more children who are not currently using an efficient method of contraception (including sterilization) - by current age and level of education T553
5.2.4B	Percentage of "Exposed" women wanting no more children who are not currently using an efficient method of contraception (including sterilization) - by current age and place of residence T553
5.2.4C	Percentage of "Exposed" women wanting no more children who are not currently using an efficient method of contraception (including sterilization) - by current age and religion T554
5.2.4D	Percentage of "Exposed" women wanting no more children who are not currently using an efficient method of contraception (including sterilization) - by current age and husband's occupation T554
5.2.4E	Percentage of "Exposed" women wanting no more children who are not currently using an efficient method of contraception (including sterilization) - by current age and pattern of work T555
5.2.4F	Percentage of "Exposed" women wanting no more children who are not currently using an efficient method of contraception (including sterilization) - by current age and years since most recent work T555
5.2.5	Percent distribution of women with at least one live birth (including any current pregnancy) according to specified contraception method used in the last closed interval - by number of children at the beginning of the interval and whether last (or current) pregnancy was wanted. T556
5.3.1	Percent distribution of currently married "Fecund" women according to pattern of contraceptive use by desire for more children and current age T557
5.3.2	Percent distribution of currently married "Fecund" women according to pattern of contraceptive use by current age and by whether total number of children desired exceeds number of living children (including any current pregnancy) T558

Table Number		
5.3.3A	Percent distribution of currently married "Fecund" women according to pattern of contraceptive use by desire for more children, level of education and current age.....	T559
5.3.3B	Percent distribution of currently married "Fecund" women according to pattern of contraceptive use by desire for more children and type of place of residence	T564

B 6. BACKGROUND CHARACTERISTICS OF RESPONDENTS TO THE INDIVIDUAL INTERVIEW

6.1.1	Percent distribution of all ever-married women according to type of place of residence - by level of education and current age	T569
6.1.2	Percent distribution of all ever-married women according to religion - by level of education and current age	T570
6.1.3	Percent distribution of all ever-married women according to husband's occupation - by level of education and current age	T571
6.1.4	Percent distribution of all ever-married women according to number of modern objects owned - by level of education and current age.....	T572
6.1.5	Percent distribution of all ever-married women according to pattern of work - by level of education and current age.....	T573
6.1.6	Percent distribution of all ever-married women according to literacy - by level of education and current age	T574
6.1.7	Percent distribution of all ever-married women according to husband's education - by level of education and current age.....	T575
6.1.8	Percent distribution of all ever-married women according to wife's most recent occupation - by level of education and current age.....	T576
6.2.1	Percent distribution of all ever-married women according to religion - by type of place of residence and current age	T577
6.2.2	Percent distribution of all ever-married women according to husband's occupation - by type of place of residence and current age ...	T578

Table Number		
6.2.3	Percent distribution of all ever-married women according to number of modern objects owned - by type of place of residence and current age.....	T579
6.2.4	Percent distribution of all ever-married women according to pattern of work - by type of place of residence and current age	T580
6.2.5	Percent distribution of all ever-married women according to childhood type of place of residence - by type of residence and current age.....	T581
6.3.1	Percent distribution of all ever-married women according to number of modern objects owned - by husband's occupation and current age	T582
6.3.2	Percent distribution of all ever-married women according to pattern of work - by husband's occupation and current age.....	T582
6.4.1	Percent distribution of all ever-married women according to husband's occupation - by religion and current age	T584
6.4.2	Percent distribution of all ever-married women according to number of modern objects owned - by religion and current age.....	T585
6.4.3	Percent distribution of all ever-married women according to pattern of work - by religion and current age	T586
6.5.1	Percent distribution of all ever-married women according to pattern of work - by number of modern objects owned and current age.....	T587

Section 1: Respondent's Background

LOCATION OF INTERVIEW(SHI, EUP, MYUN) _____

101. Do you live in this house?

YES

NO

102. Do you live in(SHI, EUP, MYUN) _____ ?

Yes No

103. Where do you live?

(INTERVIEWER: OBTAIN SHI, EUP, MYUN)

104. Have you always lived in(SHI, EUP, MYUN OF CURRENT RESIDENCE) since you were born?

YES

NO (SKIP TO 106)

105. What kind of area would you say (this, that) was when you were growing up, say to age 12? Was it countryside, a town, or a city?

COUNTRYSIDE TOWN CITY

(SKIP TO 110)

106. Where were you born?

SHI DO _____ GUN _____ EUP MYUN _____

107. In what kind of area did you live mostly when you were growing up, say to age 12? Was it in the countryside, in a town, or in a city?

COUNTRYSIDE TOWN CITY

108. Where did you live before you moved to (SHI, EUP, MYUN OF CURRENT RESIDENCE)?

SHI DO _____ GUN _____ EUP MYUN _____

109. How many years ago did you move to (SHI, EUP, MYUN OF CURRENT RESIDENCE)?

_____ YEARS AGO

110. How old are you now?

_____ YEARS OLD →

ENTER ON EVENTS CHART: CURRENT KOREAN AGE IN 1974 AND KOREAN AGES IN PREVIOUS CALENDAR YEARS BACK TO AGE 15

111. In what animal year were you born? (REFER TO EVENTS CHART)
_____ ANIMAL YEAR

112. In what year, month, and day were you born? (REFER TO EVENTS CHART)

(TO BE FILLED IN BY FIELD EDITOR)
R's DATE OF BIRTH IN SOLAR CALENDAR

YEAR	MONTH	DAY
DK <input type="checkbox"/>	DK <input type="checkbox"/>	DK <input type="checkbox"/>

YEAR	MONTH	DAY
DK <input type="checkbox"/>	DK <input type="checkbox"/>	DK <input type="checkbox"/>

113. INTERVIEWER: TICK APPROPRIATE BOX (SEE 112 ABOVE)

MONTH GIVEN

MONTH DK

114. Is the month of your birth solar or lunar calendar?

SOLAR

LUNAR

DK

115. Was that a leap month?

YES

NO

DK

116. Do you happen to know the season in which you were born - spring, summer, autumn, or winter?

SPRING

SUMMER

WINTER

AUTUMN

DK

2/3

117. Have you ever attended school?

YES

NO (SKIP TO 121)

118. What was the highest level of school you attended? Was it primary school, "new" middle school or "old" middle school, "new" high school or "old" high school, or college?

PRIMARY SCHOOL NEW MIDDLE SCHOOL OLD MIDDLE SCHOOL NEW HIGH SCHOOL OLD HIGH SCHOOL

COLLEGE OTHER (SPECIFY) _____

119. Did you graduate from (HIGHEST LEVEL ATTENDED)?

YES

NO

120. How many grades did you complete in (HIGHEST LEVEL ATTENDED)?

NO. OF GRADES COMPLETED

121. INTERVIEWER: TICK APPROPRIATE BOX (SEE 117, 118, AND 119)

NO SCHOOLING

DID NOT GRADUATE FROM PRIMARY SCHOOL

GRADUATED FROM PRIMARY SCHOOL OR MORE

122. Can you read a newspaper or magazine?

YES

NO (SKIP TO 124)

123. How often do you usually read newspapers to get news and information?

(READ CATEGORIES)

EVERYDAY A FEW DAYS A WEEK ONCE IN A WHILE NEVER

124. How often do you usually listen to radio or watch television to get news and information (READ CATEGORIES)

EVERYDAY A FEW DAYS A WEEK ONCE IN A WHILE NEVER

125. Do you have a religion which you believe in?

YES

NO (SKIP TO 128)

126. What is your religion?

BUDDHIST CONFUCIANIST PROTESTANT

CATHOLIC OTHER (SPECIFY) _____

127. How often do you usually go to a church, a temple, or any place like that? (READ CATEGORIES, IF NECESSARY)

AT LEAST ONCE A WEEK AT LEAST ONCE A MONTH A FEW TIMES A YEAR

LESS OFTEN

128. Have you ever attended any meetings of organizations like the Woman's Association, Mother's Club, Home Life Improvement Club, or others like these?

YES

NO (SKIP TO SECTION 2)

129. How many times have you attended any meetings of organizations like these in the past 12 months?

TIMES

Section 2: Maternity History

201. We want to get a complete record of all babies you have actually given birth to in all of your life. In the first place, do you have any sons of your own now living with you?

YES
NO

202. How many live with you?

203. Do you have any sons of your own who are living elsewhere?

YES
NO

204. How many live elsewhere?

205. Do you have any daughters of your own now living with you?

YES
NO

206. How many live with you?

207. Do you have any daughters of your own who are living elsewhere?

YES
NO

208. How many live elsewhere?

209. Have you ever given birth to any sons or daughters who later died? Please include ones who died immediately after birth?

YES
NO

210. How many of your sons and daughters have died?

211. INTERVIEWER: SUM ANSWERS TO 202, 204, 206, 208, AND 210 AND ENTER TOTAL HERE: SUM:

NOW ASK:

Just to make sure I have this right,

you have had _____ (SUM) births. Is that correct?

YES

NO

(PROBE AND CORRECT AS NEEDED)

212. Are you pregnant now?

YES

NO (SKIP TO 215)

DK (SKIP TO 215)

213. In what month of pregnancy are you in now? (ENTER IN EVENTS CHART)

_____ MONTHS

214. Would you prefer to have a boy or a girl?

BOY

GIRL

EITHER

OTHER _____

(SPECIFY)

215. INTERVIEWER: TICK APPROPRIATE BOX (SEE 211)

NO

	243	243. Did you or a doctor or someone else do anything to end that pregnancy early by induced abortion?															256
	244	244. Was there any other pregnancy (before your 1st child, between your 1st and 2nd child, after your last child)? (IF YES, REPEAT 236-244. IF NO, PROBE 245.)															257
	245	245. In this period, did you or a doctor or someone else do anything to end (a, another) pregnancy early by induced abortion? (IF YES, REPEAT 236-244, 243-244. IF NO, ASK 236 FOR NEXT INTERVAL. IF ANY.)															258
	246	246. CORRECT LIVE BIRTH ORDER AS NEEDED (BRACKET MULTIPLE BIRTHS)															259
	247	247. NUMBER PREGNANCIES (INCL. CURRENT PREG. COUNT MULT. BIRTH AS ONE)															260
		CURRENTLY PREGNANT (SEE 212)															261
		NO															262
		(COUNT)															263
		DATE OF INTERVIEW															264

249. INTERVIEWER: ENTER THE FOLLOWING TOTALS FROM THE LIVE BIRTH AND NON-FERTILE PREGNANCY CHARTS

(1) NUMBER OF PREGNANCIES (INCLUDING CURRENT PREGNANCY) (LAST ENTRY IN 247)		
(2) NUMBER OF TWIN BIRTHS (COUNT EACH SET OF LIVE BIRTHS AS ONE)		
(3) NUMBER OF INDUCED ABORTIONS (YES TO 243)		
(4) NUMBER OF OTHER FETAL LOSSES (NO. TO 242 PLUS NO. TO 243)		
(5) CURRENT PREGNANCY (ENTER 1 IF PREGNANT, 0 IF NOT)		
(6) NUMBER OF LIVE BIRTHS (LAST ENTRY IN 246; IF NONE, ENTER 0)		
TOTAL		

250. INTERVIEWER: CHECK THAT THE TWO TOTALS ARE EQUAL (EXCEPT FOR TRIPLETS, ETC.). IF NOT EQUAL, CHECK ENTRIES IN LIVE BIRTH AND NONFERTILE PREGNANCY CHARTS. NOTE THE FOLLOWING SPECIAL CASES INVOLVING MULTIPLE BIRTHS:

- IN ROW (2), COUNT TWIN BIRTHS AS A SET ONLY IF BOTH ARE LIVE BIRTHS. DO NOT COUNT IF ONE OR BOTH ARE STILLBIRTHS.
- IN ROW (4), COUNT AS A SINGLE FETAL LOSS IF BOTH ARE STILLBIRTHS.
- IGNORE ANY STILLBIRTH THAT ACCOMPANIES A LIVE BIRTH.

251. INTERVIEWER: TICK APPROPRIATE BOX INDICATING YOUR ASSESSMENT OF THE RELIABILITY OF ANSWERS IN SECTION 2.

GOOD FAIR POOR

252. INTERVIEWER: TICK BOXES SHOWING PRESENCE OF OTHERS AT THIS POINT IN THE INTERVIEW. (TICK ALL THAT APPLY)

NO CHILDREN HUSBAND OTHER MALES OTHER FEMALES

341

Section 3: Marriage History

301. Now, I have some questions about your married life. Are you now married, widowed, divorced, or separated?

MARRIED WIDOWED DIVORCED SEPARATED

SKIP TO 315

302. How old were you when you and your husband married? (PLOT ON EVENTS CHART)
_____ YEARS OLD

303. In what month were you married? (PLOT ON EVENTS CHART)
_____ MONTH DK

304. Is that solar or lunar calendar?

SOLAR
LUNAR
DK

305. Was that month a leap month?
YES
NO
DK

306. In what season was that?

SPRING
SUMMER
AUTUMN
WINTER

307. How old was your husband when you married him?
_____ YEARS OLD

308. Does your husband ordinarily live in your household?
YES (SKIP TO 315) NO

309. Is he away only for the time being or have you stopped living together for good?
FOR THE TIME BEING (SKIP TO 315) FOR GOOD

310. How old were you when you stopped living together for good? (PLOT ON EVENTS CHART)
_____ YEARS OLD

311. In what month was that? (PLOT ON EVENTS CHART)
_____ MONTH DK

312. Is that solar or lunar calendar?

SOLAR
LUNAR
DK

313. Was that a leap month?
YES
NO
DK

314. In what season was that?

SPRING
SUMMER
AUTUMN
WINTER

315. (Were you, have you been) married only once, or more than once?

ONLY ONCE (SKIP TO 317) MORE THAN ONCE

316. How many times have you been married altogether?
_____ TIMES

317. INTERVIEWER: CIRCLE NO. OF FORMER MARRIAGES (SUBTRACT CURRENT MARRIAGE FROM NO. GIVEN IN 316 IF "MARRIED" IN 301) IN CHART BELOW AND ASK 318-329 FOR EACH.

FORMER MARRIAGES
(PLOT ON EVENTS CHART)

	318 How old were you when you married the last. 2nd. time?	319 In what year and month was that?	IF MONTH GIVEN		320 Was that solar or lunar calendar?	321 Was that month a regular month or a leap month?	322 In what season was that?	323 How old was your husband when you married him?	324 How old that marriage end?	325 How old were that marriage ended?	326 In what year and month was that? Section 4: Contraceptive Knowledge And Use

401. Now I want to talk about a somewhat different topic. As you may perhaps know, there are various ways that a couple can delay the next pregnancy or avoid a pregnancy altogether.

Do you know of any of these ways or methods?

YES

NO

402. ASK 406-416 PREFACE QUESTIONING WITH
Just to make sure, let me describe some methods to see if you have ever heard of them. (SKIP to 406)

403. Which methods do you know of? _____

(PROBE: Anything else?) _____

INTERVIEWER: RECORD ANSWER, AND THEN TICK BOXES IN COL 1 CORRESPONDING TO THE METHODS MENTIONED.

FOR EACH METHOD MENTIONED IN 403 AND TICKED COL 1, ASK 404 USING SAME WORDINGS AS RESPONDENT.

404. Have you ever used (METHOD)? (TICK BOX IN COL 3)

405. NOW ASK 406-417, IN TURN, SKIPPING THOSE METHODS TICKED IN COL 1. PREFACE QUESTIONING WITH:

There are some other methods which you have not mentioned and I would like to find out if you might have heard of them.

COL 1	COL 2	COL 3
FROM 403	EVER HEARD	EVER USED
<input type="checkbox"/> PILL	406. One way a woman can delay the next pregnancy, or avoid getting pregnant, is to take a pill every day. COL 2. Have you ever heard of this method? COL 3. Have you ever used this method?	YES <input type="checkbox"/> NO <input checked="" type="checkbox"/> YES <input type="checkbox"/> NO <input type="checkbox"/>

COL 1	COL 2	COL 3
FROM 403	EVER HEARD	EVER USED
<input type="checkbox"/> LOOP	407. Another way is for a woman to have a loop or coil of plastic or metal, the intrauterine device (IUD), inserted in her womb by a doctor and left there. COL 2. Have you ever heard of this method? COL 3. Have you ever used this method?	YES <input type="checkbox"/> NO <input checked="" type="checkbox"/> YES <input type="checkbox"/> NO <input type="checkbox"/>
<input type="checkbox"/> OTHER FEMALE METHODS	408. Women may also use other methods to avoid getting pregnant, such as placing a diaphragm or tampon or sponge in themselves before sex, or using foam tablets or jelly or cream. COL 2. Have you ever heard of any of these methods? COL 3. Have you ever used any of these methods?	YES <input type="checkbox"/> NO <input checked="" type="checkbox"/> YES <input type="checkbox"/> NO <input type="checkbox"/>
<input type="checkbox"/> DOUCHE	409. Some women wash themselves immediately after sex, with water or perhaps some other liquid. COL 2. Have you ever heard of this method to avoid getting pregnant? COL 3. Have you ever used this method to avoid getting pregnant?	YES <input type="checkbox"/> NO <input checked="" type="checkbox"/> YES <input type="checkbox"/> NO <input type="checkbox"/>
<input type="checkbox"/> CONDOM	410. There are also some methods men use so that their wives will not get pregnant. Some men wear a condom during sex. COL 2. Have you ever heard of this method? COL 3. Did you and your husband ever use this method?	YES <input type="checkbox"/> NO <input checked="" type="checkbox"/> YES <input type="checkbox"/> NO <input type="checkbox"/>
<input type="checkbox"/> RHYTHM	411. Some couples avoid having sex on particular days of the month when the woman is most able to become pregnant. This is called the safe period or rhythm method. COL 2. Have you ever heard of this method? COL 3. Did you and your husband ever do this?	YES <input type="checkbox"/> NO <input checked="" type="checkbox"/> YES <input type="checkbox"/> NO <input type="checkbox"/>
<input type="checkbox"/> WITHDRAWAL	412. Some men practice withdrawal, that is, they are careful and pull out before climax. COL 2. Have you ever heard of this method? COL 3. Did you and your husband ever use this method?	YES <input type="checkbox"/> NO <input checked="" type="checkbox"/> YES <input type="checkbox"/> NO <input type="checkbox"/>
<input type="checkbox"/> ABSTINENCE	413. Another way is to go without sex for several months or longer to avoid getting pregnant. COL 2. Have you ever heard of this method being used? COL 3. Have you ever done this to avoid getting pregnant?	YES <input type="checkbox"/> NO <input checked="" type="checkbox"/> YES <input type="checkbox"/> NO <input type="checkbox"/>

COL 1 FROM 403		COL 2- EVER HEARD	COL 3 EVER USED
<input type="checkbox"/>	414. Some women have an operation called sterilization, such as having their tubes tied, in order not to have any more children. COL 2. Have you heard of this method?	YES <input type="checkbox"/> NO <input type="checkbox"/>	
<input type="checkbox"/>	415. Some men have an operation called vasectomy, so as not to get their wives pregnant. COL 2. Have you heard of this method?	YES <input type="checkbox"/> NO <input type="checkbox"/>	
<input type="checkbox"/>	416. Have you ever heard of any other methods which women or men can use to avoid pregnancy? Yes <input type="checkbox"/> No <input type="checkbox"/> (SKIP TO 418)		
<input type="checkbox"/>	417. What methods have you heard of? (LIST BELOW AND FOR EACH METHOD ASK QUESTION FOR COL 3)		
	¹ COL 3. Have you ever used this method?		YES <input type="checkbox"/> NO <input type="checkbox"/>
	² COL 3. Have you ever used this method?		YES <input type="checkbox"/> NO <input type="checkbox"/>
	³ COL 3. Have you ever used this method?		YES <input type="checkbox"/> NO <input type="checkbox"/>

418. INTERVIEWER: TICK APPROPRIATE BOX (SEE COL 3, 406-417)

AT LEAST ONE NOT A SINGLE
YES IN COL 3 (SKIP TO 422) YES IN COL 3

419. I want to make sure I have the correct information. Have you ever done anything or tried in any way to delay or avoid getting pregnant?

YES NO

420. What method was that?

(PROBE: Any other methods?)

(CORRECT COL 2 & 3 AS
NEEDED)

(SKIP TO 422)

421. Why is it that you have never used any method?

(PROBE: Any other reasons?)

(SKIP TO 460)

422. INTERVIEWER: TICK APPROPRIATE BOX (SEE 406, COL 3)

EVER USED PILL NEVER USED PILL (SKIP TO 438)

423. You have told me that you have used the pill. Where have you usually gotten your supplies?

HEALTH CENTER

HOSPITAL

PRIVATE DOCTOR

DRUG STORE

OTHER

(SPECIFY) _____

424. Have you ever had any difficulties in getting supplies when you needed them?

YES NO (SKIP TO 429)

425. What kinds of difficulties were they?

426. Have you ever discussed any of your difficulties in getting supplies of oral pills with a doctor, or a family planning worker, or a nurse, or anyone like that?

YES NO (SKIP TO 429)

427. With whom have you discussed any of your difficulties of this kind?

428. Have any of these discussions helped you?

YES NO

429. Have you ever experienced any side-effects from using the pill?

YES NO (SKIP TO 433)

430. What side-effects have you experienced?

431. How severe were any of the side-effects? Would you say very severe, somewhat severe, or not so severe?

VERY SEVERE SOMEWHAT SEVERE NOT SO SEVERE

432. Have you seen a doctor, or a nurse, or someone like that to have any of your side-effects treated?

YES NO

433. Have you ever had any other difficulties in using the pill?
YES NO (SKIP TO 438)

434. What difficulties have you had?

435. Have you ever discussed any of these difficulties with a doctor, or a family planning worker, or a nurse, or anyone like that?
YES NO (SKIP TO 438)

436. With whom have you discussed any of these difficulties?

437. Have any of these discussions helped you?
YES NO

438. INTERVIEWER: TICK APPROPRIATE BOX (SEE 407, COL 3)
EVER USED LOOP NEVER USED LOOP (SKIP TO 448)

439. You have told me that you have used the loop. Have you ever experienced any side effects from using the loop?
YES NO (SKIP TO 443)

440. What side-effects have you experienced?

441. How severe any of the side-effects? Would you say very severe, somewhat severe, or not so severe.
VERY SEVERE SOMEWHAT SEVERE NOT SO SEVERE

442. Have you ever seen a doctor, or a nurse, or someone like that to have any of your side-effects treated?
YES NO

443. Have you had any other difficulties in using the loop?
YES NO (SKIP TO 448)

444. What difficulties have you had?

445. Have you ever discussed any of these difficulties with a doctor, a family planning worker, or a nurse, or anyone like that?
YES NO (SKIP TO 448)

446. With whom have you discussed any of these problems?

447. Have any of these discussions helped you?
YES NO

448. INTERVIEWER: TICK APPROPRIATE BOX (SEE 410, COL 3)
EVER USED CONDOM NEVER USED CONDOM (SKIP TO 460)

449. You have told me that you and your husband have used the condom.
Where have you or your husband usually gotten your supplies?

- HEALTH CENTER
- HOSPITAL
- PRIVATE DOCTOR
- DRUG STORE
- OTHER (SPECIFY) _____

450. Have you or your husband ever had any difficulties in getting supplies when you needed them?
YES NO (SKIP TO 455)

451. What difficulties have you had?

452. Have you ever discussed any of your difficulties in getting supplies of condoms with a doctor, or a family planning worker, or a nurse or anyone like that?
YES NO (SKIP TO 455)

453. With whom have you discussed any of your difficulties of this kind?

454. Have any of these discussions helped you?
YES NO

455. Have you or your husband ever had any other difficulties in using the condom?
YES NO (SKIP TO 460)

456. What difficulties have you had?

457. Have you ever discussed any of these difficulties with a doctor, or a family planning worker, or a nurse, or anyone like that?
YES NO (SKIP TO 460)

458. With whom have you discussed any of these difficulties?

459. Have any of these discussions helped you?
YES NO

10/1

460. Have you ever attended any Mother's Club Meetings when family planning was discussed?

YES

NO (SKIP TO 462)

461. How many times have you been to any Mother's Club Meetings during the past 12 months when family planning was discussed?

_____ TIMES

462. Has anyone like a nurse or a family planning worker ever visited you in your home to discuss with you about family planning?

YES

NO (SKIP TO 464)

463. How many times has anyone like this visited you in your home during the past 12 months to discuss with you about family planning?

_____ TIMES

464. Do you know of any place where a woman around (here, where you live) could go to get information, help, or supplies for family planning if she needed it?

YES

NO (SKIP TO 469)

465. How long would it take her to go to the closest of these places if she were to go from (here, where you live)?

ONE WAY _____ HOUR _____ MINUTES DK

466. By what means of transportation would she go?

467. Have you ever been to any place to get information, help, or supplies for family planning?

YES

NO (SKIP TO 469)

468. How many times have you been to any place like this in the past 12 months for these purposes?

_____ TIMES

469. Do you know of any place where a woman around (here, where you live) could go if she wanted to get an abortion?

YES

NO (SKIP TO 472)

470. How long would it take a woman to go to the closest of these places if she were to go from (here, where you live)?

ONE WAY _____ HOUR _____ MINUTES DK

471. By what means of transportation would she go?

472. In general, what is your opinion about a woman getting an abortion? Would you say strongly approve, approve, disapprove, or strongly disapprove?

STRONGLY APPROVE

APPROVE

DIS-APPROVE

STRONGLY DIS-APPROVE

DEPENDS

DK

473. On what does it depend?

474. Do you think you could have an abortion for yourself in the future if you needed to? Would you say yes, no, or absolutely no?

YES

NO

ABSOLUTELY NO

DEPENDS

475. On what does it depend?

102

Section 5: Fertility Planning

INTERVIEWER: ENTER APPROPRIATE INFORMATION ON RECALL CHART ON REVERSE SIDE OF EVENTS CHART FOR EASE OF REFERENCE IN THIS AND SUBSEQUENT SECTIONS

APPENDIX 3

1974 KNFS Individual Questionnaire: How It Varies From the WFS Core, A Detailed Discussion

In the text a brief discussion of the ways in which the 1974 KNFS individual questionnaire varied from the WFS Core (Mark I) was given. Here these variations are presented in greater detail, section by section.

SECTION 1. RESPONDENTS BACKGROUND

The Core questions on the type of place of growth are supplemented by a question on place of birth (Q106) and questions on previous place of residence (Q108) and recency of migration (Q109). The Korean population is today characterized by a high degree of geographic mobility. These questions should provide a measure of migration status which is known to affect fertility behaviour in significant ways.

Q123 (newspaper readership) and Q124 (exposure to radio or TV) attempt to measure mass media exposure and Q125-129 (frequency of organizational participation), exposure to organized groups through which new ideas including--family planning are being--disseminated in Korean society today.

Q125-127 (religious affiliation and frequency of attendance at places of worship) were included to test once more the earlier findings in Korea that religion makes little difference in fertility behaviour. An indirect measure of "religiosity" is afforded in Q127 (frequency of attendance at places of worship) to permit classification of respondents not just by their religious affiliation but also by a measure of their commitment to it. It was assumed that if there is religious influence on fertility behavior it should be stronger among those who by attendance at their places of worship are exposed to whatever religious position there is on control of human fertility.

SECTION 2. MATERNITY HISTORY

The major difference of this section from the WFS Core is, as alluded to in the text, the integration of the birth and the non-fertile pregnancy histories, modelled more closely after the WFS's Mark II. There are other innovations in the way the integrated pregnancy history approach was applied in Korea. These innovations are presented in Appendix 4.

In terms of substance, the questions on breastfeeding (Q231-232) are asked of every live birth rather than just the last two as recommended in the Core, and induced abortion is probed as a possibility after each non-fertile pregnancy.

SECTION 3. MARRIAGE HISTORY

A series of questions (Q330-348) are devoted to the task of identifying periods of temporary separation of at least three months—a difficult task but a necessary one, given the high geogra-

phical mobility of the population and the not uncommon practice of the husbands working away from the family for extended periods of time (not to mention the forced separations during the Korean War and more recently the Vietnam War to which Korean troops were sent). Together with the information on marital breaks, obtained from the Core questions, the information on temporary separations will help in defining more accurately the periods of risk to conception than the more gross, "duration of marriage" (i.e., elapsed time since first marriage) data. The periods of separations were identified by their boundary dates in coding so that eventually they could be articulated with the relevant pregnancy intervals and periods of actual marriage to permit calculation of net periods of exposure.

SECTION 4. CONTRACEPTIVE KNOWLEDGE AND USE

Q422-469 represent questions relevant to the family planning program and the abortion situation in Korea. As mentioned in the text, these questions were adapted from the WFS's Family Planning and Abortion Modules. A review of the specific questions included in the Korean version will reveal that the adaptations were liberally made. Q424-437, Q438-447, and Q340-459 deal with supply problems, side effects, and other problems of use related to each of the major methods of contraception offered in the national program (pill, loop, and condom). They further ask whether follow-up services were available for these problems and if any of them had been helpful. This focus on follow-up services specifically in addition to accessibility of services generally was dictated by the concern of the administrators of Korea's family planning program to improve the continuation of contraceptive use, regardless of methods, among those who respond to the call for initiation of use. Q460-461 (frequency of attendance at Mother's Club meetings) and Q462-463 (frequency of home visits by family planning workers) relate to the respondent's actual contact with the program's two important channels of communication.

Q469-475, already described in the text, relate to abortion: the accessibility of place to obtain an abortion and attitudes about getting an abortion for women generally and for oneself specifically. These too depart greatly from WFS's Abortion Module but were deemed more appropriate to the Korean situation.

SECTION 5. FERTILITY PLANNING

The basic model for this section is the Fertility Planning Module recommended by WFS in connection with the Core. (Actually, what later became the Fertility Planning Module was originally included as Section 5 in the Core, as it was available for Korea in 1974). In this section, an interval-by-interval full contraceptive history was obtained (Q501-513), adapted from the WFS's Mark II Core for low fertility countries. This merely served to continue what has been common practice in previous surveys in Korea. The detailed data by each interval of contraceptive use, articulated with the pregnancy history data of Section 3, are useful for analysis that Korean investigators have been keenly interested in. The color scheme, recommended in the WFS's Fertility Planning Module, was adopted with effective results. It facilitated the work of the interviewers through this apparently complex section.

Q534-535 and Q553-555 supplement the Core questions by asking about the husband's family size and sex preferences in addition to the wife's.

All other family size and sex preference questions are asked in Section 6.

SECTION 6. FAMILY SIZE VALUES

This is a section prepared specially for the Korean survey. It expands substantially on the one set of questions on family size and sex preference (Q604-705) adopted from the WFS Core.

The major component of this section is the series of questions (Q606-608 and Q609-611) that seek the respondent's positions on the so-called Coomb's preference scales for number and sex of children.¹⁾

The Coomb's scales were included as a means to quantify the degree of son preference as well as preference for a given number of children that prevail among the Korean mothers and to facilitate analysis of these and other variables in relation to fertility and family planning behaviour in a multivariate context. The strength of son preference in Korea is legendary and one aim of this survey was to obtain more detailed measures of this topic by adopting this innovative technique.

Other questions in this section deal with family size and spacing preferences of the respondent (Q612-616), the family size preference of the husband (Q617), and the spacing preference of the relatives (Q618) --all at the time of first marriage; the number of siblings the respondents (Q619) and the husband (Q620) had; and whether or not the husband was the first born or not (Q621) -- a matter of considerable significance, with fertility implications, in the traditional, patrilineal and patriarchal family system.

Q601-603, at the beginning of this section, were added to ascertain once again, following the series of questions in Section 5, whether or not the very last pregnancy was "wanted" or not. This piece of information, to the extent that it is reliable, can be used as a rough index of the success of contraceptive efforts in a population on the premise the "unwanted" pregnancies would be reduced as contraceptive efforts succeed.

SECTION 7. WORK HISTORY AND OPPORTUNITY

In this section, several questions suggested from the WFS's Economic Module are added. Q722-726 deal with the perception of work opportunity and Q727-731 with future intention of labor force participation. Q732-734 ask about the parent's educational aspirations for children and assessment of the economic burden associated with their fulfillment. Q735-742 then ask about the respondent's expectation and certainly as to whether children would live with her after marriage, give part of their wages when they start earning, support her in her old age and help with chores around the house. These questions concern the role of women or children in the family; differential expectations with regard to these roles; are expected to influence family size, sex preference, and fertility decisions.

Extended family living is still common in Korea, though on the decline. The extent of involvement in the traditional family system is measured by Q743-750 (living with parents or how often they are seen). Family type can be coded from the household composition data, too. These data together should give an adequate measure of the family structure variable, the context in which fertility decisions are made.

Here are a few additional questions in this section which expand on the Core only slightly:

1) For a discussion of the theory and methodology pertaining to the Coombs scales, see Clyde Coombs, Lolagene Coombs, and Gary H. McClelland, "Preference scales for number and sex of children," *Population Studies*, Vol. 2 (July 1975), 273-298.

Q705 and Q717 ask about the number of employees at the place of employment, Q718 and Q719 ask about the amount of earnings from current or most recent work since marriage, and Q721, number of hours of work per week. These were adapted either from the Economic Module or the Mark II Core.

SECTION 8. CURRENT OR LAST HUSBANDS BACKGROUND

This section follows the WFS Core quite closely. The questions added here are similar to those added in earlier sections dealing with the wife's background or work experience: Q804 (place of birth), Q815 (average monthly income), and Q818 and Q821 (number of people at place of employment or employed by husband). The husband's income data (Q815) is supplemented by Q822-832 about total household income and Q824 (perception of adequacy of income to meet family needs). These questions, too, were adapted from either the Economic Module or the Mark II Core.

Finally, Q825-836, which are the same questions as Q836-845 of the household schedule, are repeated here to obtain household data for those few respondents who happened to be visiting in the household where the interview took place. For these few respondents, the characteristics of the household in which they happened to be interviewed would not apply and would have to be obtained separately asking these questions here.

It should be clear from the foregoing, detailed discussion that the basic principle in designing Korea's questionnaire was to start with the WFS's Core, to maintain comparability with the world wide effort, and to expand on it to meet the interests and needs specific to Korea either by selectively adopting or adapting items and/or ideas suggested by the various WFS modules or by Mark II Core or other efforts at large or by devising new questions that would give a better understanding of the Korean fertility situation. The items above and beyond the Core, whatever their source, were dictated by their relevance for fertility studies in Korea, based on past research here and/or new directions suggested by similar efforts elsewhere.

APPENDIX 4

A Special Feature; Calendar-Year Approach to Pregnancy History

Various approaches have been devised in fertility surveys to improve the reporting of pregnancies, which tend to be underreported depending on how many there were, how long ago they occurred, how they were terminated, and whether, if live born, they survived or not.¹⁾ Both the Mark I and Mark II versions developed by the WFS represent efforts in this direction, each version being adapted to the respective, general situation to which it is addressed: the developing, high fertility countries and the developed, low fertility countries. In Mark I, addressed to the high fertility countries, it is assumed that reporting would be difficult but at least the live births would be better recalled than the non-fertile pregnancies. Hence, the focus is on the birth history. The non-fertile pregnancies are obtained separately and primarily for the purpose of uncovering live births that may have been missed because of early death. It is further assumed that contraceptive practice is still marginal in many of these countries and recent in others, and so contraceptive history is restricted to the open and the penultimate birth intervals. In Mark II, addressed to the low fertility countries, it is assumed that most pregnancies could be reliably reported because of the small number each woman is likely to have had, and therefore both live births and non-fertile pregnancies are obtained in a single, integrated chart, though the live births are elicited and recorded first, followed by other pregnancy interval.

In Korea the situation is more complex and required a bold, new approach. Fertility is still moderately high, though declining quite rapidly. Contraception is wide-spread, but, in addition, induced abortion has increased in recent years. Badly needed are not only reliable estimates of fertility--especially in the absence of a reliable vital statistics registration system as noted earlier--but also of induced abortions and contraceptive effectiveness.

These data needs, coupled with the cultural factors, noted earlier (See pp. 16-17 of the text), that affect the manner in which dates are reported in Korea, led to the development of a novel approach in obtaining pregnancy history, referred to hereafter and "the calendar-year approach" for reasons that should presently become obvious.

The approach has indigenous origin, having been tried successfully in a cruder form in the 1971 Fertility and Abortion Survey. The basic components of this approach, as refined for the 1974 Korean National Fertility Survey, are described below. (See pp. 8-15 of the Individual Questionnaire, reproduced in Appendix 4).

1. A row is provided for each calendar year spanning the entire reproductive years (15-49) of the oldest of the eligible women. This means there would be at least 35 lines, one for each of the calendar years from 1940 through 1974, the year of the survey. Three additional rows (1937, 1938, and 1939) are added to allow for marriages before age 15 and/or ambiguities in age reporting.
2. To pages facing each other are needed for each unit of about 10 years, with the questions pertaining to live births printed on the left-hand page and the questions pertaining to non-

1) For an example, which has come to be identified as the "Bogue Approach", see Donald J. Bogue and Elizabeth J. Bogue, *Techniques of Pregnancy History Analysis*, Family Planning Research and Evaluation Manual No. 4, Community and Family Study Center, University of Chicago, 1969, pp. 26-40.

fertile pregnancies on the right-hand page, facing the former. The rows on both pages are lined up and identified by the appropriate calendar years. Each row, demarcated by solid lines, is further divided by dotted lines into three sub-rows to permit recording of more than one pregnancy in a given calendar year.

3. All live births are recorded on the left-hand page in the rows (the middle sub-rows, to be exact) corresponding to the calendar years in which they are reported to have occurred.
4. Once all the live births that a woman reports on the basis of the series of questions on the left-hand page (Q 218-232) are recorded, a wavy line is drawn through the middle sub-row on the right-hand page corresponding to each of the rows with a live birth on the left-hand page. The resulting rows with the wavy lines now define all birth intervals, whose width are easily gauged visually.
5. For each birth interval, including the interval from first marriage to the first live birth and interval since the last live birth (or the open birth interval), a probe is made to ascertain whether there were any other pregnancies in the given interval and is repeated until the respondent indicates that there were no more. Then, for each pregnancy elicited, information is obtained on date of termination, gestation period, and mode of termination--including, in the case of Korea, induced abortion.

The advantages of this approach, if administered properly, are numerous. First, through the interval-by-interval probing after the initial reporting of live births, the respondent is helped to recall any other live births that may have been missed in the initial round for various reasons (such as early death or simply recall lapse). Second, the same probing procedure helps the respondent to recall her pregnancies and, with the help of an additional probe that the Korean version includes, induced abortions as well. Third, the probing, whether for additional live births, miscarriages, stillbirths, or induced abortions, is facilitated by the ease with which the interviewer can identify the relevant birth intervals and even more, the widths of the intervals. This procedure is simpler than the approach that instructs the interviewer to identify "long intervals" by mental calculation from the dates already reported and to probe for possible additional pregnancies. Fourth, the decision to probe in this approach is not left to the question sequence and applied to each birth interval. Fifth, unlike other approaches, this one provides ample space for recording of events, making the task of interviewing and transcription much easier, and thereby reducing errors from these sources.

Some may object to the number of pages this approach requires and the apparent complexity of the procedure. However, if it helps to overcome the problems of underreporting that plagues all fertility surveys, the number of pages that is required is not a compelling argument against its use. As for the apparent complexity of the procedure, Korean experience is that with good training the interviewers can easily learn it and with appropriate supervision use it efficiently and effectively in the field.

In addition to the basic components of this approach described so far, there are several auxiliary components dictated further by the peculiar, Korean situation, having to do with the system of age-reckoning and reporting of dates. They are described below:

- 1) At the head of each row to the left of the calendar designation, there are three additional columns that show from left to right: the number of years ago the given calendar year of the interviewer, in this case 1974 (or the Korean age of a child if born in the given calendar year); the animal year corresponding to the given calendar year; and a blank column in which to enter the Korean age of the given calendar year, starting from her Korean age as

of 1974, obtained from Q110 of Section 1, and going back each calendar to age 15. All of these entries can be used in varying combinations to determine the appropriate row, or calendar year, in which to enter a given event. Essentially they answer the probes: In what year was the event? How old were you then? How many years ago did it occur? Or, if a live birth, in addition: How old is the child now? In what animal year was he born?

- 2) A separate form called the "Events Chart" (reproduced on pp. below) was prepared for use in connection with the pregnancy, marriage, and separation histories. The basic purpose of the form was to facilitate the recording of pregnancies, marital breaks, and temporary separations in such a way as to avoid impossible overlaps between them. Impossible overlaps are particularly difficult to detect because different events tend to get reported in different calendars. Live births, for example, tend most often to get reported in the lunar calendar but other events less so. The Events Chart provided a row for each calendar year, from 1973 to 1974, and twelve columns to a row, each column representing the solar month of each year. Imposed on each row were heavy line segments representing the lunar months, articulated with the corresponding solar months. In the last column of each row was shown the lunar date corresponding to the last day (December 31) of the given solar year. Guided by these, the interviewer could record a given event, whether reported in the lunar or the solar calendar, in the proper row and column and detect immediately any impossible overlaps. Different symbols were used for different events, and if impossible overlaps were indicated, the interviewer would probe further to untangle the sequence of events and ascertain the proper dates. The first three columns of each row were the same as those used in the pregnancy history chart, described above. They facilitated the calendar-year determination for the given event. In the column for the animal year, a leap month, if any, was shown in parentheses to alert the interviewer to the need to probe for it if the date of an event was reported in the lunar calendar.

The actual sequence in the use of these auxiliary components of the calendar-year approach to the pregnancy history, under discussion here, was to use the Events Chart first to record the pregnancies in such a way as to avoid impossible overlaps and, to fill in the pregnancy history chart in the main interview schedule.

Finally, the reverse side of the Events Chart--the side that is labeled the "Recall Chart"--should be noted. The interviewers made the appropriate entries in the upper part of this chart to be used as an aid in the following skip instructions especially in Section 5 (Fertility Planning). The lower part of this chart was used to assist the respondents in answering Q717 and Q818 (size of place of employment) and Q823 (household income), by offering them these categories.

APPENDIX 5

Supervisor's Manual and Interviewer's Manual: Table of Contents

A. SUPERVISORS MANUAL

Introduction

- 1) General organization of the survey
 - 1.01) Training
 - 1.02) General field work procedure
- 2) The survey tasks
 - 2.01) Survey director's instructions
 - 2.02) Field supplies
 - 2.03) Organizing Travel
 - 2.04) Introduction and accomodation in the sampling area
 - 2.05) Interviewer's conduct
 - 2.06) Briefing of interviewers on field conditions
 - 2.07) Assignment of interviewers
 - 2.08) Sampling
 - 2.09) Scrutinizing household schedules and questionnaires
 - 2.10) Spot cnecking for eligibility
 - 2.11) Checking quality of selecting interviewers
 - 2.12) Continuation of interviewer's training during field work
 - 2.13) Reporting of problems to headquarters
 - 2.14) Control sheets
 - 2.15) Collecting completed questionnaires
 - 2.16) Other administrative duties
 - 2.17) Community level questionnaire
- 3) Dealing with non-contact and refusals
 - 3.01) Non-contacts
 - 3.02) Refusals
- 4) Details of field work control sheets
 - 4.01) The household interview
 - 4.02) The individual interview
 - 4.03) Interviewer control sheets
 - 4.04) Supervisor's weekly record
- 5) Editing the questionnaire
 - 5.01) The household questionnaire
 - 5.02) The individual fertility questionnaire

B. INTERVIEWERS MANUAL

Part I* Introduction

- a) The 1974 Korean National Fertility Survey: Aims and Objectives
- b) An overview of the Survey: Its Main Component

Part II. Principles of Interviewing

- a) Characteristics of the Interview
- b) Starting the Interview
 - 1) Gaining Access to the Respondent
 - 2) Call-backs and Revisits
 - 3) Need for Privacy
 - 4) Building Up a Good Interviewing Relationship
- c) How to Interview

Curricula for Field Supervisor and Interviewer
Training Sessions

A. Supervisor Training Session

Twenty-five supervisors, including the 3 roving supervisor, were trained one week in advance of the training of the interviewers and participated further in the three-week training session for the latter. (10-24 August, 1974).

<u>Date</u>	<u>Subject</u>
19 Aug. 1974	1) Welcome and opening 2) WFS/KNFS objectives 3) Survey procedure 4) Interview technique 5) Sampling & household selection
20 Aug. 1974	1) Household schedule 2) Reproductive physiology 3) F.P. method 4) Current demographic trend in Korea
21 Aug. 1974	1) Individual questionnaire, section 1 and 2 2) National family planning program 3) Induced abortion
22 Aug. 1974	1) Individual questionnaire, section 3 and 4 2) Interview V.T.R. and family planning slides 3) Individual questionnaire, section 5 and 6
23 Aug. 1974	1) Individual questionnaire, section 7 and 8 2) Discussions on sampling procedure 3) Discussions on supervisors manual
24 Aug. 1974	1) Discussions on household listing 2) Discussions on questionnaires 3) General discussions prior to interviewer's training

B. Interviewer's Training Sessions (26 Aug.-13 Sept., 1974)

<u>Date</u>	<u>Subject</u>
26 Aug. 1974	1) Welcome opening ceremony 2) General orientation 3) Interview technique 4) Demonstration of let dummy interview through VTR

27 Aug. 1974	1) Household schedule 2) Reproductive physiology and F.P. method 3) Sampling procedure
28 Aug. 1974	1) Individual questionnaire, section 1 and 2 2) Induced abortion 3) National family planning program
29 Aug. 1974	1) Individual questionnaire, section 3 and 4 2) Current demographic trend of Korea 3) Interview situation through VTR
30 Aug. 1974	1) Individual questionnaire section 5 and 6 2) Recording practice through VTR 3) Review of interviewer's manual (General part)
31 Aug. 1974(AM)	1) Observation on F.P. exhibition room 2) Review of common errors from recording results
2 Spet. 1974	1) Individual questionnaire, section 7 and 8 2) 2nd dummy interview on complicated one (Section 1-6) 3) Further training in use of household schedule
3 Spet. 1974	1) Recording practice through VTR (section 1-8) 2) Review of results on 2nd dummy interview 3) Discussion of most common error
4 Sept. 1974	1) Review of recording problem and guidance to field practice 2) Field practice
5 Sept. 1974	1) Individual and groups assessment of previous day's recording and editing 2) Editing procedures
6 Sept. 1974	Field work (4 cases per each interviewers)
7 Spet. 1974(AM)	1) Editing previous day's recording 2) Review of interviewer manual
<u>Date</u>	<u>Subject</u>
9 Sept. 1974	1) Organization of field work 2) Discussion on field work, individual reports and problems encountered
10 Sept. 1974	1) Field work 2) Discussion of field work
11 Sept. 1974	1) Further training on editing procedures 2) Recording practice 3) Editing practice
12 Sept. 1974	1) Recording and editing practice 2) Final discussion on interviewer's manual and questionnaire 3) Practical consideration of working in the field
13 Sept. 1974	1) Preparation for field work
14 Spet. 1974	Departure

APPENDIX 7

Notes on Construction of Variables

1. INTRODUCTION

Most of the variables used in the tabulations were derived directly from the household and individual questionnaires, either from a single question, or from straightforward combinations of answers. A number of the more complex variables, however, may require some amplification concerning their construction from the raw data. Two of these variables, critical to the interpretation of the findings of this report, are discussed here.

2. EXPOSURE STATUS (V 317)

Of the total number of respondents to the individual questionnaire, all those who reported a current pregnancy were classified as belonging to the first category of this variable. Among the women remaining, those currently widowed, divorced, or separated formed the second category of exposure status. Currently-married non-pregnant women who have contraceptively sterilized* constitute the third category, and throughout this report are referred to "fecund" women currently practicing contraception. Those sterilized for non-contraceptive reasons or stating that they are infecund are grouped together as the fourth category. The remaining body of respondents--currently-married, non-pregnant, and able to bear children--from the fifth category of exposure status.

3. PATTERN OF CONTRACEPTIVE USE (V540)

This variable, used extensively in Section 3.8 and 3.9 was derived from a number of questions concerning family planning attitudes and practice. In broad terms, the respondents were trichotomized into (1) never users, (2) past but not current users, and (3) current users of contraception.

Women who reported never using any method were by fecundity status, and those who were fecund further categorized according to intent for future use.

Past but not current users (excluding sterilized women) were also divided by fecundity status. Those currently fecund were then classified by their most recent use of contraception with regard to birth intervals: use in the open interval, use in the last closed interval, and earlier use.

Current users were sub-divided into those sterilized for contraceptive purposes and those presently using any other method. The construction of V540, Pattern of Contraceptive Use, may be summarized as follows:

NEVER

01 Intends future use

*either the respondent or her husband.

- 02 Does not intend future use
- 03 No need for future use (not fecund)

PAST BUT NOT CURRENT

- 04 Used in last open birth interval
- 05 Used in last closed birth interval (not in open interval)
- 06 Used earlier
- 07 Not currently fecund

CURRENT

- 08 Contraceptively sterilized (respondent or husband)
- 09 Currently using

Appendix 8

Sampling Errors

1. INTRODUCTION

The principal aim of a descriptive sample survey such as this one is to derive estimates of characteristics of a population (or sub-population such as a region) from a probability sample drawn from the population. In many instances the process involves estimating an average quantity in the population (e.g., the mean number of live births per woman in the population) by an average from the sample. The difference between the estimate and the true value can be termed the total error in the process, and this is in turn a combination of errors of two types: non-sampling errors and sampling errors. Non-sampling errors are generally deviations which would be present even if the entire population was sampled: for example, reporting errors, mistakes in coding and punching, coverage errors. Sampling errors are deviations caused by limiting the enquiry to a sample of the population.*

If a probability sample is taken, then the particular sample obtained in the survey is one of a large number of all possible samples which could have been selected using the given sample design. The estimates derived from different samples would differ from each other. The expected value of an estimate is an average of the estimates from different samples, and the sampling deviation is the difference between the observed sample estimate and the expected value. The sampling or standard error of the estimate is a measure of the expected magnitude of the sampling deviation. One of the advantages of a probability sample is that the sampling error can be estimated from the results of the one sample which is actually available.

Apart from non-sampling errors, all estimates considered in this study are approximately unbiased; that is, the expected value from all possible samples approximates the true population value of interest. Thus if non-sampling errors are small, the sampling error measures the size of the expected deviation of the sample estimate from the true population value. In the presence of non-sampling errors, the sampling error should be interpreted as the lower bound of this quantity.

A common and convenient criterion asserts that the true value (apart from non-sampling errors) lies within a range of twice the standard error on either side of the sample value. This is how standard errors presented in this appendix may be interpreted. If, for example, in the case of the variable "percentage of women preferring their next child to be a boy" the sample estimation is 67 percent, and the standard error is 2 percent, then one can assert that (except for the non-sampling errors) there is a probability of 0.95 that the true value lies between 63 and 71 percent. Another way of saying this is that the odds are only one in twenty that the true value lies outside the range. This range (63 to 71 percent—i.e., sample mean $\pm 2 \times$ standard error) is thus called the "95 percent confidence interval".

The same concept applies to estimator of difference of means between two subclasses of the sample. If, for example, in the case of the variable mentioned above the sample value for one subclass is 65 percent, and that for the other subclass is 70 percent and, further, the standard error of the difference (70-65=5 percent) is 2 percent, then one can assert that the true difference between the subclasses is 5 ± 4 —i.e. 1 to 9 percent.

- * These do not include errors in the implementation of the sample design.
- By "subclass" we mean part of the sample composed of individuals possessing certain specified characteristics. For example, individuals "aged under 25 years" may define a subclass of interest.

2. DISCUSSION OF THE MAIN RESULTS

The sample design for the Korean National Fertility Survey has been described elsewhere in this report. It is a single area stage selfweighting sample consisting of 318 clusters-191 urban and 127 rural. Clusters were census enumeration districts; households in sample clusters were listed and a sample of households was selected in each cluster. A large sample consisting of approximately 18,000 households was used to collect data on general fertility and mortality. However, the sampling errors presented in this appendix relate to the smaller sample for the individual interview. This second sample consists of just over 5,400 eligible women successfully interviewed, giving an average of 17 respondents per cluster. The computation procedure for the results discussed below takes into account the actual structure of the sample, and in particular the fact that the sample is a stratified clustered sample.

Sampling errors have been computed for 18 variables of substantive interest over the whole sample, as well as for 14 subclasses and 6 subclass differences. All these results were computed for the total sample as a domain, and also for the urban and rural domains separately (the latter included small towns). The 14 subclasses considered are the main control variables used in tabulations of the survey results (though categories considered here are necessarily coarser than those in the tabulations) and are rather well distributed over sample clusters. In this appendix only results likely to be of direct relevance to the user of the survey report are presented; more detailed results can be made available to the specialised user on request.

2.1 Table 1

This table defines the 18 variables for which sampling errors have been computed and gives, for the total sample, the following:

- m = mean or percentage estimated
SE = standard error for the actual (clustered) sample
n = the appropriate sample size for the variable
DEFT = the "design effect" which compares the relative error of the actual clustered sample with what the error would have been had the sample been selected by simple random sampling of individuals. $DEFT = SE^2/SR$ where SR, is estimated by the usual simple random sample formula.
s = the standard deviation, defined as $s = SR \cdot \sqrt{n}$. This is a measure of the variability between individuals. Though it is estimated from the sample results, it is a characteristic of the population, and not of the particular sample design.

Table 1 also shows SE and n for the urban and rural domains. The main results to emerge from this table are:

- 1) that, for the sample as a whole, or for the two main domains, sampling errors are generally small compared with the corresponding estimates; and
- 2) that DEFT are also small (often near 1.0, mostly under 1.5), implying that sampling precision has not been greatly affected by clustering of the sample.

Part (B) of Table 1 defines the subclasses used for the present calculations. Here subclasses have been treated as characteristics (dichotomous '1' = individual belongs to the subclass; '0' = individual does not belong to the subclass) distributed over the sample. The standard errors shown are not of direct relevance to the present survey since these variables do not actually comprise the basic survey estimates. However, it may be noted that the standard errors are generally small. In addition, DEFTs are small, implying that all the subclasses considered are well distributed over sample clusters.

2.2 Table 2

This table displays detailed results for computed standard errors, along with estimated means or percentages and relevant sample bases, for all variables and subclasses considered. The main points to be noted are as follows:

- 1) The most noticeable feature of the results is that sampling errors are generally small. For all variables and all subclasses considered, standard errors are well under 5 percent of the mean in most cases, and often under 1 to 2 percent.
- 2) Individual results show significant scatter. Since the estimates of sampling errors from a sample are themselves subject to sampling fluctuation, attention should be focussed on the general pattern of results rather than on individual figures.

The results on the whole do confirm rather well to an overall pattern on the basis of which Table 3 has been constructed. Table 3 gives, for each variable, the approximate variation of standard error with the sample base, for any subclass of the sample.

2.3 Table 3

The table gives, for each variable, approximate values of the standard errors for various sample bases-i.e., for various subclass sizes. This table can be used directly to obtain approximate standard error for any cell of the tabulations. In fact, this may be used also for the rural/urban domains separately, as well as for any subclass within each domain. This generalization applies in particular to variables with small DEFT (say ≤ 1.2 , see Table 1). For variables with larger DEFT, it may be stated that, very approximately, for sample bases above 500, Table 3 underestimates standard errors for the urban domain by 5 percent and for the rural domain by 10 percent.

Examples

Suppose that, for a subclass of size 185, the estimated percentage of women "who have ever used a method of contraception" is 50. Reading, for this variable, the value from the column with n nearest to the subclass size (n=200), the standard error 3.5 percent. This means that it can be asserted that (apart from non-sampling errors) the true percentage is in the range $50 \pm 2(3.5)$ -i.e. 43 to 57; 43 to 57 is the "95 percent confidence interval" for the estimate.

Similarly if, for a subclass of size 720, the estimated length of the open birth interval is 45 months, the standard error from Table 3 (n=501 to 1000) is 2 months. The 95 percent confidence interval is $45 \pm 2(2)$ -i.e. 41 to 49 months.

2.4 Table 4

Sampling errors can be particularly relevant in interpretation of the fertility and other differentials observed from the survey results. Generally speaking the present report is concerned as much with differentials as with absolute levels of fertility and factors associated with it. Even for a relatively "efficient" sample such as the present one, many observed differentials are statistically insignificant once the sample has been divided by the introduction of necessary control variables.

For the set of variables considered here, Table 3 can also be used to obtain, in an approximate way, standard errors for subclass differences, including rural/urban differentials. The appropriate sample size to be used in Table 3 for differences of two subclasses of sizes, say n_1 and n_2 , is given in Table 4.

Suppose that a mean (or proportion) value is estimated for two subclasses of any size, and that these means are to be compared and tested to see whether or not the observed difference is statistically significant. The procedure to obtain an approximate value for the standard error of the difference between means for the two subclasses is as follows:

Select sample bases n_1 and n_2 nearest to the actual sizes of the two subclasses. Read n corresponding to these values (n_1, n_2) from Table 4 and use that n in Table 3 to obtain the approximate value of the standard error for the difference between the two subclass means. It should be stressed that this procedure is an approximate one.

Examples

Suppose we want to estimate the standard error for the difference for the "mean number of births in the past five years" (Variable No. 5) between two subclasses of sizes 350 and 625. The nearest sample bases (n_1, n_2) shown in Table 4 are respectively 400 and 600, and the n corresponding to them is 200. From Table 3 the standard error for this variable for $n=200$ is 0.065. If, for example, the means for the two subclasses being considered are 0.80 and 0.88 respectively, it can be asserted that the true value of the difference lies in the range $0.08 \pm 2(0.065) = -0.05$ to $+0.21$. Since this range includes both positive and negative values, it cannot be asserted that the true mean for the second subclass is higher than the true mean for the first subclass. In fact, the actual difference can be in a direction opposite to that observed from the sample. Note that this does not establish that the means for the two subclasses are the same, only that the observed difference in the subclass means can be explained by sampling variability alone.

As another example, consider the variable "length of the first birth interval in months", for two subclasses of sizes 875 and 410. The means for the two subclasses are, say, 18 and 23 months. The nearest sample sizes shown in Table 4 are $n_1=400$ and $n_2=1000$, and the n corresponding to them is 300. From Table 3 the standard error for this variable for $n=300$ is 0.7. Hence it can be asserted that the true value of the difference between two means is 5 ± 1.4 - i.e. in the range 3.6 to 6.4. Since this range does not include the value zero, the observed difference is "statistically significant".

TABLE 1. STANDARD ERRORS AND DEFT'S FOR VARIABLES OVER THE TOTAL SAMPLE, AND STANDARD ERRORS OVER THE RURAL AND URBAN DOMAINS SEPARATELY.
A. SUBSTANTIVE (DEPENDENT) VARIABLES

Variable	Total Sample*					Urban		Rural	
	m	s	SE	n	DEFT	SE	n	SE	n
1. Age at first marriage (for women aged 25 or over, who marry before age 25)	19.4	2.66	0.06	4369	1.39	0.06	2187	0.09	2182

Procedure: Select n_1 and n_2 nearest to the sizes of the two subclasses. Read n from Table 4, column for that n in Table 3 gives approximately standard error for the difference between the two subclass means for a particular variable.

3. SOME TECHNICAL CONSIDERATIONS

In this section we provide the basic formula used for computing sampling errors for clustered samples and make some additional comments on the results presented in Tables 1 to 4. These should be of interest to the more specialised readers.

3.1 Outline of the computation procedure

Since in the present sample clusters were selected by systematic sampling, it is necessary for the purpose of sampling error computation to define strata by pairing adjacent clusters. To supply the basic computation formula, we consider a ratio statistic

$$r = y/x,$$

where y and x are "aggregates" (unweighted for the present self-weighting sample design). Suppose that the sample (or a domain of study, e.g. urban or rural) is composed of H strata and from any stratum, h , m_h clusters have been sampled. In any cluster i (in stratum h), let

$y_{hi,j}$ = the value of variable y for the individual j

$y_{hi} = \sum_j y_{hi,j}$, the sum of all values $y_{hi,j}$ for all sample individuals in the cluster (note that

the present sample is self-weighting).

$y_h = \sum_{i=1}^{m_h} y_{hi}$, the sum of values over stratum h , and

$$y = \sum_{i=1}^N y_i, \text{ the sum over the whole sample (or a domain of study).}$$

Similar terms can be defined for the variable x .

The variance (square of the standard error) of the ratio estimate $r=y/x$ is estimated as

$$\text{var}(r) = \frac{1-f}{x^2} \sum_{h=1}^H \left\{ \frac{m_h}{m_h-1} \left[\frac{\sum_{i=1}^{m_h} z_{hi}^2}{m_h} - \frac{z_{hi}^2}{m_h} \right] \right\}, \quad (1)$$

where f is the overall sampling fraction - here negligible;

$$z_{hi} = y_{hi} - r \cdot x_{hi}, \text{ and}$$

$$z_h = y_h - r \cdot x_h.$$

Equation (1) also applies to estimates like means, proportions or percentages which can be regarded as special cases of ratios. The denominator, x , may be a "count" variable (i.e., number of individuals in the cluster) or it may be a substantive variable like y . (The above equations also apply to subclasses of the sample: individuals not belonging to a subclass of interest are simply ignored.)*

3.2. Further comments on the Tables

(1) Table 1: DEFT

As mentioned earlier, DEFT compares the relative error of the actual clustered sample with what it would have been had the sample been selected by simple random sampling of individuals. DEFT is defined as the ratio:

$$\text{DEFT} = \text{SE SR},$$

where SE is estimated from equation (1), and SR from:

$$\text{SR}^2 = \frac{1-f}{n^2} \left[\sum y_{hi}^2 - \frac{(\sum y_{hi})^2}{n} \right], \quad (2)$$

where n is the total sample (or a domain) size, and ' Σ ' is the sum for all individuals over the sample (or domain). For a particular sample design, cluster size and variable, DEFT is a measure of the loss in sampling precision due to clustering of the sample. The two main factors on which its magnitude depends are the average cluster size and the homogeneity (corresponding to a particular variable) within these clusters. For samples (or for subclasses thereof) with very small clusters, or for variables with little within-cluster homogeneity, DEFT can be expected to approach unity, which implies that no sampling precision has been lost through clustering.

(2) Tables 2 and 3: Patterns of results for the subclasses

In spite of the scatter of the computed results for individual subclasses given in Table 2, the pattern of results for subclasses is generally well approximated from the results for the whole sample by the relationship

$$\left. \begin{aligned} SE_t^2 &= SE_t^2 \left[\frac{n_t}{n_s} + (DEFT_t - 1) \right] DEFT_t^2 \\ &= SR_t^2 \left[\frac{n_t}{n_s} + (DEFT_t - 1) \right] \end{aligned} \right\} (3)$$

where the suffix 't' refers to the total sample (of size n_t) and the suffix 's' to a subclass of size n_s .

Figure 1 illustrates this point for ten variables; the same is true of the remaining variables. The solid lines in Figure 1 correspond to the variation of SE_t with n_s if the sample was a simple random sample ($DEFT_t = 0$); on the log scale used these are straight lines. The dotted lines correspond to equation (3), using the computed values for $DEFT_t$ for the variables.

However, for certain variables and certain subclasses, equation (3) which is, in fact, a semiempirical relationship, is not adequate for predicting SE_t . This is particularly the case for three variables—number of children ever born, length of the open birth interval, and percentage of fecund women wanting no more children. These variables are strongly related to life-cycle—i.e. to age or marriage duration of the respondent. The standard error here is obviously related to the mean or percentage being estimated, which in turn varies considerably from one subclass to another. Nevertheless, we find that in this particular case exceptional subclasses (with, say, exceptionally low value for the mean of the variable) can be dealt with by replacing SR_t in equation (3) by

$$(f \cdot SR_t),$$

where $f = \text{a constant}$, < 1 ; $f = \frac{1}{2}$ gives a reasonable fit.

These results are used in constructing Table 3 which is perhaps the most directly relevant one for the user of survey results.

(3) Table 4: Standard errors for subclass differences

Variance of the difference of two subclass means is given by the following formula. Denoting the second subclass in the pair by prime ('), the variance of the difference of two ratios is given by

$$\text{var}(r-r') = \text{var}(r) + \text{var}(r') - 2 \text{cov}(r, r'), \quad (4)$$

where the covariance is given by

$$\text{cov}(r, r') = \frac{1-f}{x^2} \sum_{k=1}^K \left[\frac{m_k}{m_k-1} \left[\frac{z_k \cdot z'_k}{\sum_{i=1}^{m_k} z_{ki} z'_{ki}} - \frac{z_k \cdot z'_k}{m_k} \right] \right]$$

Usually $\text{cov}(r, r')$ is positive due to positive correlation between individuals in the two subclasses who belong to the same clusters of the sample. Hence the variance of the difference of estimates for two subclasses tends to be smaller than the sum of variances for the two estimates. Assuming equation (3) to be valid, the sum of variances for the two means is

$$SE_t^2 + SE_{t'}^2 = SR_t^2 \left\{ \frac{n_t}{n_s} + 2(DEFT_t - 1) \right\}, \quad (5)$$

where n'' is half the harmonic mean of the two subclass sizes (n_s and n'_s):

$$\frac{1}{n''} = \frac{1}{n_s} + \frac{1}{n'_s} \quad \text{or} \quad n'' = \left\{ \frac{n_s \cdot n'_s}{n_s + n'_s} \right\}, \quad (6)$$

Generally, equation (5) over-estimates $\text{var}(r-r')$ somewhat, unless the two subclasses come from entirely different clusters—as, for example, when rural and urban differentials are being considered.

The increase in variance due to clustering of the sample tends to be relatively less significant when subclass differences are being considered. Equation (7) below, which completely ignores clustering, will generally under-estimate $\text{var}(r-r')$:

$$SR_t^2 + SR_{t'}^2 = SR_t^2 \left\{ \frac{n_t}{n''} \right\}, \quad (7)$$

Table 4 actually gives n'' , as a function of (n_s, n'_s)—called in that Table n_1 and n_2 and the method recommended there for estimating standard errors of subclass differences assumes $\text{var}(r-r')$ to be given by

$$[\text{var}(r-r')] = SR_t^2 \left\{ \frac{n_t}{n''} + (DEFT_t - 1) \right\}, \quad (8)$$

which is mid-way between equations (5) and (7). Actually, the difference between these three equations in the present case is generally quite small since

- i. $DEFT_t$ for the variables considered is usually not large; and
- ii. For the subclass sizes usually of most interest n'' , is small compared to n_t (say $n_s'' < 0.1 n_t$) so that the first term in (5) or (8) dominates.

Hence we can use (8) to provide reasonable estimates for standard errors for differences between any pairs of subclasses.

* The ratio estimator is not unbiased; the magnitude of the bias depends upon the variability of the cluster sizes z_{ki} . However, for the present sample the bias is generally negligible since the coefficient of variation of cluster sizes is small not only for the sample as a whole, but also for each of the subclasses considered; it is under or around 0.05 in all cases. This implies that equation (1) provides an approximately unbiased estimate over the subclasses.
