Evidence for X(3872) in Pb-Pb Collisions and Studies of its Prompt Production at $\sqrt{s_{NN}} = 5.02$ TeV

A. M. Sirunyan *et al.**
CMS Collaboration

 (Received 25 February 2021; revised 2 September 2021; accepted 22 December 2021; published 19 January 2022)

The first evidence for X(3872) production in relativistic heavy ion collisions is reported. The X(3872) production is studied in lead-lead (Pb-Pb) collisions at a center-of-mass energy of $\sqrt{s_{NN}} = 5.02$ TeV per nucleon pair, using the decay chain $X(3872) \rightarrow J/\psi\pi^+\pi^- \rightarrow \mu^+\mu^-\pi^+\pi^-$. The data were recorded with the CMS detector in 2018 and correspond to an integrated luminosity of 1.7 nb^{-1} . The measurement is performed in the rapidity and transverse momentum ranges $|y| < 1.6$ and $15 < p_T < 50 \text{ GeV}/c$. The significance of the inclusive X(3872) signal is 4.2 standard deviations. The prompt X(3872) to $\psi 2S$ yield ratio is found to be $\rho^{\text{Pb-Pb}} = 1.08 \pm 0.49(\text{stat}) \pm 0.52(\text{syst})$, to be compared with typical values of 0.1 for pp collisions. This result provides a unique experimental input to theoretical models of the X(3872) production mechanism, and of the nature of this exotic state.

DOI: [10.1103/PhysRevLett.128.032001](https://doi.org/10.1103/PhysRevLett.128.032001)

The X(3872), also known as $\chi_{c1}(3872)$, is an exotic particle that was first observed by the Belle Collaboration [1], and then confirmed and studied by other experiments at electron-positron [2,3] and hadron colliders [4–8]. The quantum numbers of the X(3872) have been narrowed down by the CDF [9], and later determined to be $J^{PC} = 1^{++}$ by the LHCb [10] Collaborations. However, the nature of this particle is still not fully understood and interpretations in terms of conventional charmonium (a bound state of charm-anticharm quarks), $D^*(2010)^0 \bar{D}^0$ molecules [11], tetraquark states [12], and their admixture [13] have been proposed. The production and survival of the X(3872) in a quark-gluon plasma (QGP), a deconfined state of quarks and gluons [14,15], or after the QGP, in a hadronic phase, is expected to depend upon the X(3872)'s internal structure [16,17]. Thus, the recent large dataset of lead-lead (Pb-Pb) collisions at a center-of-mass energy of $\sqrt{s_{NN}} = 5.02$ TeV per nucleon pair, delivered by the Large Hadron Collider (LHC) at CERN at the end of 2018, opened new opportunities to probe the nature of this exotic state [18–20].

It is expected that in relativistic heavy ion collisions, the formation of the QGP could enhance or suppress the production of the X(3872) particle. Coalescence mechanisms could enhance the X(3872) production yield [16,19]. These mechanisms can be modeled via the overlap of the

density matrix of the constituents in an emission source with the Wigner function of the produced particle [21]. Therefore, the enhancement of the X(3872) production in the QGP would depend on the spatial configuration of the exotic state. Moreover, a longer distance between the quarks and antiquarks that constitute the state could also lead to a higher X(3872) dissociation rate, similar to that from the mechanism of quarkonium suppression in heavy ion collisions [22]. Therefore, the study of the X(3872) state in the QGP may be used as a tool to distinguish a compact tetraquark configuration with a radius ~ 0.3 fm from a molecular state with a radius greater than 1.5 fm [23]. Such a measurement would be complementary to the recent evidence for the radiative decay $X(3872) \rightarrow \psi 2S\gamma$ in proton-proton (pp) collisions reported by LHCb Collaboration [24], which does not support a pure $D^*(2010)^0 \bar{D}$ molecular interpretation. In addition, measurements of prompt X(3872) production could provide an interesting test of the statistical hadronization model, which assumes that the produced matter is in thermodynamic equilibrium at the phase transition to hadrons [25,26].

In this Letter, the first evidence for X(3872) production in Pb-Pb collisions at $\sqrt{s_{NN}} = 5.02$ TeV is reported. The Pb-Pb sample corresponds to an integrated luminosity of 1.7 nb^{-1} . The X(3872) candidates are reconstructed through the decay chain $X(3872) \rightarrow J/\psi\pi^+\pi^- \rightarrow \mu^+\mu^-\pi^+\pi^-$, and are measured in the $15 < p_T < 50 \text{ GeV}/c$ and $|y| < 1.6$ kinematic region. At the LHC energies, the inclusive X(3872) yields in pp and Pb-Pb collisions contain a significant nonprompt contribution coming from b hadron decays [8]. The nonprompt X(3872) component is related to the medium-modified beauty hadron production in heavy ion collisions, which is

out of the scope of this Letter. Here, we focus on the prompt component, from charm quark fragmentation, for which the ratio ρ^i (i is pp or Pb-Pb) between the corrected yields of X(3872) and $\psi 2S$ mesons [where the $\psi 2S$ is reconstructed with the same final-state particles in order to reduce systematic uncertainties] is presented

$$\rho^i = \frac{N_i^{X(3872) \rightarrow J/\psi \pi \pi}}{N_i^{\psi 2S \rightarrow J/\psi \pi \pi}}. \quad (1)$$

The ratios in pp and Pb-Pb collisions are connected to the nuclear modification factors $R_{AA}^{X(3872)}$ and $R_{AA}^{\psi 2S}$ (the meson yield ratio in nucleus-nucleus and pp interactions normalized by the number of inelastic nucleon-nucleon collisions) via the following relation:

$$\rho^{\text{Pb-Pb}} = \rho^{pp} \frac{R_{AA}^{X(3872)}}{R_{AA}^{\psi 2S}}. \quad (2)$$

The CMS apparatus [27] is a multipurpose, nearly hermetic detector, designed to trigger on [28,29] and identify electrons, muons, photons, and (charged and neutral) hadrons [30–33]. A global reconstruction algorithm [34] combines the information provided by the all-silicon inner tracker and by the crystal electromagnetic and brass-scintillator hadron calorimeters, operating inside a 3.8 T superconducting solenoid, with data from gas-ionization muon detectors interleaved with the solenoid return yoke. Information from the hadron forward (HF) calorimeter is used for performing off-line event selection and determining centrality (the degree of overlap between the two colliding nuclei). The results refer to the collisions with 0%–90% centrality, i.e., the top 90% events based on the total transverse energy deposition in both HF detectors [35], which corresponds to the 90% of collisions having the largest overlap of the two nuclei.

Events of interest were selected in real time using the CMS two-tiered trigger system: the first level (L1), composed of custom hardware processors [28], and the high-level trigger (HLT), consisting of a farm of processors running a version of the full event reconstruction software optimized for fast processing [29]. The selection required the presence of two muon candidates, with at least one muon reconstructed in the outer muon spectrometer, and one muon reconstructed using information from both the outer muon spectrometer and the inner tracker. The dimuon candidate invariant mass is required to be $1 < m_{\mu\mu} < 5 \text{ GeV}/c^2$. For the off-line analysis, events have to pass a set of selection criteria designed to reject events from background processes (beam-gas collisions, beam scraping events, and electromagnetic interactions) as described in Ref. [36]. Events are required to have at least one reconstructed primary interaction vertex formed by two or more tracks, with a distance from the center of the

nominal interaction point of less than 15 cm along the beam axis. The shapes of the clusters in the pixel detector have to be compatible with those expected from particles produced by a Pb-Pb collision [37]. In order to select hadronic collisions, the Pb-Pb events are also required to have at least two towers (i.e., a geometrically defined group of calorimeter cells) in each of the HF detectors with total energy deposits of more than 4 GeV per tower. This analysis is restricted to events within centrality 0%–90%, for which the hadronic event selection is fully efficient. Multiple-collision events (pileup) have a negligible effect on the measurement, since the average number of additional collisions per bunch crossing is approximately 0.002.

Dedicated Pb-Pb X(3872) and $\psi 2S$ Monte Carlo (MC) simulated samples were generated in order to estimate the acceptance and selection efficiencies, to study the background components, and to evaluate systematic uncertainties. The PYTHIA8 v212 [38] Tune CP5 [39] was used to generate the X(3872) and $\psi 2S$ signals at $\sqrt{s_{NN}} = 5.02 \text{ TeV}$. It was assumed that X(3872) and $\psi 2S$ are unpolarized. Since the X(3872) cannot be generated by PYTHIA, the $\chi_{c1}(1P)$ particle is used, with a modified mass of $3.8716 \text{ GeV}/c^2$ [40]. The $\chi_{c1}(1P)$ has the quantum numbers $J^{PC} = 1^{++}$, identical to those of the X(3872). The X(3872) particle was forced to decay into $J/\psi \pi^+ \pi^-$ (assuming the ρ resonance dominates the pion pair spectrum [7,8]), followed by the J/ψ meson decaying into two muons. Final-state radiation was generated using PHOTOS2.0 [41]. The $\chi_{c1}(1P) \rightarrow J/\psi \pi^+ \pi^-$ decay is generated with EvtGen. The samples with prompt (fragmenting in charm quarks) and nonprompt (originating from b hadron decays) $\psi 2S$ /X(3872) production are generated separately. Each PYTHIA event is embedded in a Pb-Pb collision event generated with HYDJET1.8 [42], which is tuned to reproduce global event properties such as the charged-hadron p_T spectrum and particle multiplicity.

The X(3872) signal is extracted in the following steps. Each muon candidate must be matched to a triggered muon and have $p_T^\mu > 3.5 \text{ GeV}/c$ in the interval $|\eta^\mu| < 1.2$, $p_T^\mu > (5.47 - 1.89|\eta^\mu|) \text{ GeV}/c$ in the interval $1.2 < |\eta^\mu| < 2.1$, or $p_T^\mu > 1.5 \text{ GeV}/c$ in the forward region $2.1 < |\eta^\mu| < 2.4$. Two muons of opposite sign, with an invariant mass within $\pm 150 \text{ MeV}/c^2$ of the world-average J/ψ meson mass [40] are selected to reconstruct a J/ψ candidate. The opposite-sign muon pairs are fitted with a common vertex constraint and are kept if the χ^2 probability of the fit is greater than 1%, thus reducing the background from charm and beauty hadron semileptonic decays. The X(3872) and $\psi 2S$ candidates are built by combining the J/ψ candidates with two additional tracks, which have $p_T > 0.9 \text{ GeV}/c$, $|\eta| < 2.4$ and pass a high purity selection, assumed to be produced by two pions. Only candidates that have $15 < p_T < 50 \text{ GeV}/c$ and $|y| < 1.6$ are considered. Then, a kinematic fit to the $J/\psi \pi^+ \pi^-$ system is performed, requiring that the four tracks originate from a common vertex and forcing the

mass of the dimuon pair to be equal to the nominal J/ψ mass [40]. The selection is further optimized, using a boosted decision tree (BDT) algorithm [43]. The $X(3872)$ decay vertex probability, the radial distance between the pion and the J/ψ candidate momentum vectors [$\sqrt{(\Delta\eta)^2 + (\Delta\phi)^2}$, where ϕ is the azimuthal angle], and the p_T of each pion are used in the BDT algorithm to distinguish signal and combinatorial background formed by random combinations of tracks. For the multivariate training, the $X(3872)$ signal sample is taken from simulation, and the background sample consists of data from the sidebands of the $X(3872)$ meson peak (i.e., $0.07 < |m - m_{X(3872)}| < 0.128 \text{ GeV}/c^2$). The nominal BDT selection is chosen in order to maximize the statistical significance of $X(3872)$, defined as $S/\sqrt{(S+B)}$ where S and B are the numbers of $X(3872)$ and background in the signal region, respectively. Because there is no reliable theoretical calculation available for the $X(3872)$ production, an estimation of the $X(3872)$ cross section is obtained from data, by extracting the signal yield in data when applying a tight BDT cut. This is used in conjunction with the MC-calculated efficiency to obtain the yield for each BDT cutoff value. The BDT selection determined in this way is applied to entries in the whole invariant mass range from 3.62 to 4 GeV/c^2 in data.

The raw inclusive yields of $X(3872)$ and $\psi(2S)$ are extracted by an extended unbinned maximum-likelihood fit. A double-Gaussian function with a common mean but independent widths is used to model the signal component for each of the $X(3872)$ and $\psi(2S)$ peaks. This was preferred to a single-Gaussian or a Breit-Wigner function since it described better (i.e., superior χ^2 of the fit) the signal shape in MC simulations. For describing the combinatorial background, mostly produced by the random combination of a J/ψ candidate with tracks that are not coming from $X(3872)$ or $\psi(2S)$ decay, a 4th-order polynomial is used, which gives the best fit in terms of χ^2 per degrees of freedom and stability during all studies. For the signal, only the magnitude of the two peaks is left free in the fit, the rest [the mean and widths of the two Gaussian functions, as well as their relative contribution to the signal yield in either $X(3872)$ or $\psi(2S)$ peaks] are set to the values derived from simulation. The five parameters of the combinatorial background are all allowed to float. The invariant mass range considered for the fit is 3.62 to 4 GeV/c^2 . The invariant mass fits for both the inclusive and nonprompt samples, with BDT selection optimized for $X(3872)$, are shown in Fig. 1. The significance of the inclusive $X(3872)$ signal against background-only hypothesis is 4.2 standard deviations. The systematic uncertainty (described below) contributing to this significance is the one related to the $X(3872)$ invariant mass fit. After performing a likelihood scan for each alternative signal and background shape considered, the significance was calculated as the square

FIG. 1. Invariant mass distribution of $m_{\mu\mu\pi\pi}$ in Pb-Pb collisions, for the inclusive (upper) and b -enriched (bottom) samples. The vertical lines represent statistical uncertainties in the data. The results of the unbinned maximum-likelihood fits for the signal + background and background alone are also shown by the solid and dashed lines, respectively. The pull distribution is represented by the shaded bars. The $X(3872)$ peak mass resolution, $\sigma_{X(3872)}$, calculated at the half-maximum of the signal-shape distribution, is also listed for reference.

root of the logarithm of the profile likelihood ratio where the signal is zero, with the smallest value obtained being chosen among all scans.

The contribution from b hadron decays is subtracted from the inclusive result using the “pseudoproper” decay length l_{xy} , defined as the distance in the transverse plane L_{xy} between the vertex formed by the 4-tracks and the primary vertex, corrected by the transverse Lorentz boost of the candidate: $l_{xy} = L_{xy} m_{J/\psi\pi\pi} c / |\vec{p}_T|$. The prompt-component fraction (f_{prompt}) is estimated using a cutoff-based method in the following way. Since the l_{xy} of the prompt component was found in MC studies to be smaller than 0.1 mm, the prompt fraction, f_{prompt} , can be derived from (i) the raw inclusive yield, N_{incl} , obtained from the fit to the invariant mass distributions of all candidates, shown in Fig. 1, and (ii) $N_{b\text{-enr}}$, the “ b -enriched” yield, obtained from a fit to the invariant mass distribution only containing candidates that passed the selection $l_{xy} > 0.1 \text{ mm}$, also shown in Fig. 1. In addition, $N_{b\text{-enr}}$ has to be corrected to account for nonprompt candidates, with $l_{xy} < 0.1 \text{ mm}$, that have been missed: $f_{\text{nonprompt}}^{b\text{-enr}} = N_{\text{nonprompt}}(l_{xy} > 0.1 \text{ mm}) / N_{\text{nonprompt}}$. The correction was obtained from simulation. The raw prompt fraction is then calculated as

$$f_{\text{prompt}} = 1 - \frac{N_{b\text{-enr}} / f_{\text{nonprompt}}^{b\text{-enr}}}{N_{\text{incl}}}, \quad (3)$$

FIG. 2. The yield ratio $\rho^{\text{Pb-Pb}}$ of prompt X(3872) over $\psi(2S)$ production in Pb-Pb collisions at $\sqrt{s_{\text{NN}}} = 5.02$ TeV. The vertical bars (boxes) correspond to statistical (systematic) uncertainties. The yield ratios ρ^{pp} of prompt X(3872) over $\psi(2S)$ production in pp collisions at $\sqrt{s} = 8$ TeV, measured by ATLAS [8], and at $\sqrt{s} = 7$ TeV, measured by CMS [7] are also shown.

separately for X(3872) and $\psi 2S$ states. The corrected yield of the prompt component can then be derived as

$$N^{i \rightarrow J/\psi \pi \pi} = N_{\text{raw}}^i f_{\text{prompt}}^i / (\alpha \epsilon_{\text{reco}} \epsilon_{\text{sel}})^i, \quad (4)$$

where i is X(3872) or $\psi 2S$, α is the acceptance, ϵ_{reco} is the candidate reconstruction efficiency and ϵ_{sel} is the candidate selection efficiency. Since the two states are reconstructed in the same decay channel and are relatively close in mass, their corresponding $\alpha \epsilon_{\text{reco}}$ values are similar. The choice of the BDT optimization criteria results in ϵ_{sel} being higher for the X(3872) than for the $\psi 2S$.

The measurement of $\rho^{\text{Pb-Pb}}$ is affected by several sources of systematic uncertainty, arising from the candidate selection, invariant mass fit, and efficiency corrections. To estimate the systematic uncertainty associated with the BDT selection, the BDT cutoff values are varied within a range that allows a robust invariant mass fit procedure (i.e., signal statistical significance larger than 2), and for each variation all factors in Eq. (4) are recalculated, separately for X(3872) and $\psi 2S$. The maximum difference of the final $\rho^{\text{Pb-Pb}}$ value from the nominal result (40%) is quoted as the systematic uncertainty. The relatively large $\rho^{\text{Pb-Pb}}$ uncertainty associated with BDT cutoff value is the convolution of mainly two causes: the BDT variables distribution differences in data and MC samples for the X(3872) meson, and the statistical limitation of the signal in data. The largest differences (~ 2 standard deviations) between data and MC samples are in the distributions of the p_T of

the pions, and the radial distance between the pion and the J/ψ candidate momentum vectors.

The uncertainty in the invariant mass fit (8.0%) is calculated by adding in quadrature the maximum deviations from the nominal result to that found using two alternative fitting functions for both signal and background. For the signal, one variation consists of using a triple-Gaussian function, while for the other the signal width of the nominal fit is allowed to float to account for the resolution difference between data and MC samples. Other choices for the signal shape (e.g., one-Gaussian function) were not considered because of their poor-quality fits. For the background, the fit function is changed once to a third-order polynomial (as an exponential function or lower-order polynomials could not describe the data), and the fit range is also changed from $3.62\text{--}4$ GeV/ c^2 to $3.62\text{--}3.9$ GeV/ c^2 to exclude the right-hand shoulder.

The efficiency corrections obtained from simulation are sensitive to how well the p_T spectrum of the X(3872) and $\psi 2S$ candidates is modeled. The uncertainty related to the simulated p_T shape is evaluated by comparing the reconstruction and selection efficiencies calculated using the default PYTHIA MC sample, with another MC sample in which the p_T distributions of X(3872) and $\psi 2S$ are tuned to reproduce the extracted X(3872) and $\psi 2S$ p_T and y spectra obtained in data, by performing mass fits in bins of X(3872) and $\psi 2S$ p_T and y . The p_T and y spectra of the alternative MC samples are allowed to vary within the statistical uncertainties in data. The mean of the differences between efficiencies from the alternative MC samples and the default PYTHIA MC due to the variation of p_T and y spectra, which is 13%, is quoted as the systematic uncertainty.

The uncertainties in the trigger efficiency in the muon reconstruction and identification are evaluated using single muons from J/ψ meson decays in both simulated and collision data, with the tag-and-probe method [44,45]. This combined uncertainty is found to be negligible, below 1%. Scale factors, calculated as the ratio of data to simulated efficiencies as a function of p_T^μ and η^μ , are applied to each dimuon pair on a muon-by-muon basis. The uncertainties of the scaling factors from tag-and-probe studies are quoted as systematic uncertainties.

To estimate the uncertainty in the prompt fraction arising from potential differences between the resolution in data and simulation, a template fit of the l_{xy} distribution in data is performed using prompt and nonprompt l_{xy} templates from simulation. Data are binned in l_{xy} , and an invariant mass fit is performed to extract the inclusive yield in each l_{xy} bin. This background-subtracted l_{xy} distribution is then fitted using a two component fit, which includes the prompt and nonprompt l_{xy} templates from simulation. The widths of the simulated DCA distributions are varied by a floating scale factor, and the best simulated smearing scale factor to match data is determined by minimizing the χ^2 of the two-component fit. The difference between the ratio of the

prompt fractions of X(3872) to $\psi 2S$ using the template fit method and the nominal result (8.1%) is quoted as a systematic uncertainty.

When calculating the uncertainties in the ratio of the acceptance-corrected yields of prompt X(3872) production over prompt $\psi 2S$ production, the uncertainties of X(3872) and $\psi 2S$ yields are assumed to be independent except for the systematic uncertainties from muon reconstruction, efficiencies, and prompt fractions.

The ratio $\rho^{\text{Pb-Pb}}$ between the prompt X(3872) and $\psi 2S$ mesons is shown in Fig. 2, together with ρ^{pp} measured as a function of p_T . The pp data were measured at $\sqrt{s} = 7$ and 8 TeV, in the $|y| < 1.2$ and $|y| < 0.75$ intervals, respectively [7,8,10]. The 7 TeV result was derived using the CMS Collaboration published ratio of the inclusive yields [7] and prompt fractions [7,46]. From Fig. 2 it is clear that the prompt ρ^{pp} does not depend significantly on collision energy or rapidity. In pp collisions at $\sqrt{s} = 8$ TeV, in the kinematic range of $16 < p_T < 22$ GeV/ c , the ρ^{pp} measured by the ATLAS Collaboration is $0.106 \pm 0.008(\text{stat}) \pm 0.004(\text{syst})$ [8]. This is to be compared to the prompt $\rho^{\text{Pb-Pb}}$ measured in this Letter, $\rho^{\text{Pb-Pb}} = 1.08 \pm 0.49(\text{stat}) \pm 0.52(\text{syst})$.

In the interval $15 < p_T < 20$ GeV/ c , the yield of the prompt $\psi 2S$ in Pb-Pb collisions was reported to be significantly suppressed with respect to pp collisions, $R_{AA}^{\psi 2S} = 0.142 \pm 0.061(\text{stat}) \pm 0.020(\text{syst})$ [47]. This leads, using Eq. (2), to an $R_{AA}^{\text{X}(3872)}$ central value larger than 1 [i.e., enhancement of the prompt X(3872) yield in Pb-Pb compared to pp collisions]. However, the uncertainties are such that $R_{AA}^{\text{X}(3872)}$ is compatible with 1 within ~ 1 standard deviation, and with $R_{AA}^{\psi 2S}$ within ~ 2 standard deviations. Thus, it is possible that in Pb-Pb collisions, the prompt X(3872) yield has either no suppression with respect to pp collisions, or as much suppression as the $\psi 2S$ state. The much larger data sample expected in Run 3 at the LHC will answer whether $R_{AA}^{\text{X}(3872)}$ is different from $R_{AA}^{\psi 2S}$ and significantly above unity. It may answer whether the $\psi 2S$ meson production (a bound state of a c and \bar{c} quarks, with $r \sim 0.9$ fm) [48], is affected differently by the medium produced in Pb-Pb collisions than the X(3872) state (that could be made of c , \bar{c} , u , and \bar{u} quarks, with a radius of $r \sim 0.3$ or $r > 1.5$ fm), the difference in both size and quark content playing a role into their production mechanisms. It will also answer whether the X(3872) prompt state production is different in Pb-Pb collisions compared to pp collisions. The question whether X(3872) is a tetraquark or a molecule cannot yet be answered, because of the statistical limitation of the data, and the disagreement among models. For example, while the AMPT transport model [16] predicts $R_{AA}^{\text{molecule}} \gg R_{AA}^{\text{tetraquark}}$ with $R_{AA}^{\text{molecule}} > 1$, the TAMU transport model [17] predicts $R_{AA}^{\text{molecule}} \sim R_{AA}^{\text{tetraquark}}/2$ [albeit, considering only the X(3872) from regeneration processes].

In summary, the first evidence for X(3872) production in heavy ion collisions is presented using lead-lead collisions at a center-of-mass energy of $\sqrt{s_{\text{NN}}} = 5.02$ TeV per nucleon pair, recorded with the CMS detector. The X(3872) state is reconstructed using the decay chain $\text{X}(3872) \rightarrow J/\psi \pi^+ \pi^- \rightarrow \mu^+ \mu^- \pi^+ \pi^-$. The measurement is performed for transverse momentum values of the X(3872) of $15 < p_T < 50$ GeV/ c and rapidity $|y| < 1.6$. The significance of the inclusive X(3872) signal is 4.2 standard deviations. The ratio $\rho^{\text{Pb-Pb}}$ between the prompt X(3872) and $\psi 2S$ yields times their branching fractions into $J/\psi \pi^+ \pi^-$ is found to be $1.08 \pm 0.49(\text{stat}) \pm 0.52(\text{syst})$, to be compared with typical values of 0.1 for pp collisions. This result provides a unique experimental input to theoretical models of the X(3872) production mechanism, and of the nature of this exotic state.

We congratulate our colleagues in the CERN accelerator departments for the excellent performance of the LHC and thank the technical and administrative staffs at CERN and at other CMS institutes for their contributions to the success of the CMS effort. In addition, we gratefully acknowledge the computing centers and personnel of the Worldwide LHC Computing Grid and other centers for delivering so effectively the computing infrastructure essential to our analyses. Finally, we acknowledge the enduring support for the construction and operation of the LHC, the CMS detector, and the supporting computing infrastructure provided by the following funding agencies: BMBWF and FWF (Austria); FNRS and FWO (Belgium); CNPq, CAPES, FAPERJ, FAPERGS, and FAPESP (Brazil); MES (Bulgaria); CERN; CAS, MoST, and NSFC (China); COLCIENCIAS (Colombia); MSES and CSF (Croatia); RIF (Cyprus); SENESCYT (Ecuador); MoER, ERC PUT and ERDF (Estonia); Academy of Finland, MEC, and HIP (Finland); CEA and CNRS/IN2P3 (France); BMBF, DFG, and HGF (Germany); GSRT (Greece); NKfIA (Hungary); DAE and DST (India); IPM (Iran); SFI (Ireland); INFN (Italy); MSIP and NRF (Republic of Korea); MES (Latvia); LAS (Lithuania); MOE and UM (Malaysia); BUAP, CINVESTAV, CONACYT, LNS, SEP, and UASLP-FAI (Mexico); MOS (Montenegro); MBIE (New Zealand); PAEC (Pakistan); MSHE and NSC (Poland); FCT (Portugal); JINR (Dubna); MON, RosAtom, RAS, RFBR, and NRC KI (Russia); MESTD (Serbia); SEIDI, CPAN, PCTI, and FEDER (Spain); MOSTR (Sri Lanka); Swiss Funding Agencies (Switzerland); MST (Taipei); ThEPCenter, IPST, STAR, and NSTDA (Thailand); TUBITAK and TAEK (Turkey); NASU (Ukraine); STFC (United Kingdom); DOE and NSF (USA). Individuals have received support from the Marie-Curie program and the European Research Council and Horizon 2020 Grant, Contracts No. 675440, No. 724704, No. 752730, and No. 765710 (European Union); the Leventis Foundation; the Alfred P. Sloan Foundation; the Alexander von Humboldt Foundation; the Belgian Federal Science

Policy Office; the Fonds pour la Formation à la Recherche dans l'Industrie et dans l'Agriculture (FRIA-Belgium); the Agentschap voor Innovatie door Wetenschap en Technologie (IWT-Belgium); the F. R. S.-FNRS and FWO (Belgium) under the “Excellence of Science—EOS”—be.h Project No. 30820817; the Beijing Municipal Science & Technology Commission, No. Z191100007219010; the Ministry of Education, Youth and Sports (MEYS) of the Czech Republic; the Deutsche Forschungsgemeinschaft (DFG), under Germany's Excellence Strategy—EXC 2121 “Quantum Universe”—390833306, and under project number 400140256—GRK2497; the Lendület (“Momentum”) Program and the János Bolyai Research Scholarship of the Hungarian Academy of Sciences, the New National Excellence Program ÚNKP, the NKFI research grants 123842, 123959, 124845, 124850, 125105, 128713, 128786, and 129058 (Hungary); the Council of Science and Industrial Research, India; the Ministry of Science and Higher Education and the National Science Center, contracts Opus 2014/15/B/ST2/03998 and 2015/19/B/ST2/02861 (Poland); the National Priorities Research Program by Qatar National Research Fund; the Ministry of Science and Higher Education, Project No. 0723-2020-0041 (Russia); the Programa Estatal de Fomento de la Investigación Científica y Técnica de Excelencia María de Maeztu, grant MDM-2015-0509 and the Programa Severo Ochoa del Principado de Asturias; the Thalís and Aristeia programs cofinanced by EU-ESF and the Greek NSRF; the Rachadapisek Sompot Fund for Postdoctoral Fellowship, Chulalongkorn University and the Chulalongkorn Academic into Its 2nd Century Project Advancement Project (Thailand); the Kavli Foundation; the Nvidia Corporation; the SuperMicro Corporation; the Welch Foundation, Contract C-1845; and the Weston Havens Foundation (USA).

^aDeceased.

^bAlso at Vienna University of Technology, Vienna, Austria.

^cAlso at Université Libre de Bruxelles, Bruxelles, Belgium.

^dAlso at IRFU, CEA, Université Paris-Saclay, Gif-sur-Yvette, France.

^eAlso at Universidade Estadual de Campinas, Campinas, Brazil.

^fAlso at Federal University of Rio Grande do Sul, Porto Alegre, Brazil.

^gAlso at Universidade Federal do Mato Grosso do Sul (UFMS), Nova Andradina, Mato Grosso do Sul, Brazil.

^hAlso at Universidade Federal de Pelotas, Pelotas, Brazil.

ⁱAlso at University of Chinese Academy of Sciences, Beijing, China.

^jAlso at Institute for Theoretical and Experimental Physics named by A.I. Alikhanov of NRC ‘Kurchatov Institute’, Moscow, Russia.

^kAlso at Joint Institute for Nuclear Research, Dubna, Russia.

^lAlso at British University in Egypt, Cairo, Egypt.

^mAlso at Fayoum University, El-Fayoum, Egypt.

ⁿAlso at Purdue University, West Lafayette, Indiana, USA.

^oAlso at Université de Haute Alsace, Mulhouse, France.

^pAlso at Tbilisi State University, Tbilisi, Georgia.

^qAlso at Erzincan Binali Yildirim University, Erzincan, Turkey.

^rAlso at CERN, European Organization for Nuclear Research, Geneva, Switzerland.

^sAlso at RWTH Aachen University, III. Physikalisches Institut A, Aachen, Germany.

^tAlso at University of Hamburg, Hamburg, Germany.

^uAlso at Brandenburg University of Technology, Cottbus, Germany.

^vAlso at Institute of Physics, University of Debrecen, Debrecen, Hungary.

^wAlso at Institute of Nuclear Research ATOMKI, Debrecen, Hungary.

^xAlso at MTA-ELTE Lendület CMS Particle and Nuclear Physics Group, Eötvös Loránd University, Budapest, Hungary.

^yAlso at IIT Bhubaneswar, Bhubaneswar, India.

^zAlso at Institute of Physics, Bhubaneswar, India.

^{aa}Also at G.H.G. Khalsa College, Punjab, India.

- ^{bb} Also at Shoolini University, Solan, India.
- ^{cc} Also at University of Hyderabad, Hyderabad, India.
- ^{dd} Also at University of Visva-Bharati, Santiniketan, India.
- ^{ee} Also at INFN Sezione di Bari, Università di Bari, Politecnico di Bari, Bari, Italy.
- ^{ff} Also at Italian National Agency for New Technologies, Energy and Sustainable Economic Development, Rome, Italy.
- ^{gg} Also at Centro Siciliano di Fisica Nucleare e di Struttura Della Materia, Catania, Italy.
- ^{hh} Also at Riga Technical University, Riga, Latvia.
- ⁱⁱ Also at Malaysian Nuclear Agency, MOSTI, Kajang, Malaysia.
- ^{jj} Also at Consejo Nacional de Ciencia y Tecnología, Mexico City, Mexico.
- ^{kk} Also at Warsaw University of Technology, Institute of Electronic Systems, Warsaw, Poland.
- ^{ll} Also at Institute for Nuclear Research, Moscow, Russia.
- ^{mm} Also at National Research Nuclear University 'Moscow Engineering Physics Institute' (MEPhI), Moscow, Russia.
- ⁿⁿ Also at Institute of Nuclear Physics of the Uzbekistan Academy of Sciences, Tashkent, Uzbekistan.
- ^{oo} Also at St. Petersburg State Polytechnical University, St. Petersburg, Russia.
- ^{pp} Also at University of Florida, Gainesville, Florida, USA.
- ^{qq} Also at Imperial College, London, United Kingdom.
- ^{rr} Also at P.N. Lebedev Physical Institute, Moscow, Russia.
- ^{ss} Also at Budker Institute of Nuclear Physics, Novosibirsk, Russia.
- ^{tt} Also at Faculty of Physics, University of Belgrade, Belgrade, Serbia.
- ^{uu} Also at Università degli Studi di Siena, Siena, Italy.
- ^{vv} Also at INFN Sezione di Pavia, Università di Pavia, Pavia, Italy.
- ^{ww} Also at National and Kapodistrian University of Athens, Athens, Greece.
- ^{xx} Also at Universität Zürich, Zurich, Switzerland.
- ^{yy} Also at Stefan Meyer Institute for Subatomic Physics, Vienna, Austria.
- ^{zz} Also at Burdur Mehmet Akif Ersoy University, Burdur, Turkey.
- ^{aaa} Also at Şırnak University, Şırnak, Turkey.
- ^{bbb} Also at Department of Physics, Tsinghua University, Beijing, China.
- ^{ccc} Also at Near East University, Research Center of Experimental Health Science, Nicosia, Turkey.
- ^{ddd} Also at Beykent University, Istanbul, Turkey.
- ^{eee} Also at Istanbul Aydin University, Application and Research Center for Advanced Studies (App. & Res. Cent. for Advanced Studies), Istanbul, Turkey.
- ^{fff} Also at Mersin University, Mersin, Turkey.
- ^{ggg} Also at Piri Reis University, Istanbul, Turkey.
- ^{hhh} Also at Ozyegin University, Istanbul, Turkey.
- ⁱⁱⁱ Also at Izmir Institute of Technology, Izmir, Turkey.
- ^{jjj} Also at Bozok Universitetesi Rektörlüğü, Yozgat, Turkey.
- ^{kkk} Also at Marmara University, Istanbul, Turkey.
- ^{lll} Also at Milli Savunma University, Istanbul, Turkey.
- ^{mmm} Also at Kafkas University, Kars, Turkey.
- ⁿⁿⁿ Also at Istanbul Bilgi University, Istanbul, Turkey.
- ^{ooo} Also at Hacettepe University, Ankara, Turkey.
- ^{ppp} Also at Adiyaman University, Adiyaman, Turkey.
- ^{qqq} Also at Vrije Universiteit Brussel, Brussel, Belgium.
- ^{rrr} Also at School of Physics and Astronomy, University of Southampton, Southampton, United Kingdom.
- ^{sss} Also at IPPP Durham University, Durham, UK.
- ^{ttt} Also at Monash University, Faculty of Science, Clayton, Australia.
- ^{uuu} Also at Bethel University, St. Paul, Minneapolis, USA.
- ^{vvv} Also at Karamanoğlu Mehmetbey University, Karaman, Turkey.
- ^{www} Also at California Institute of Technology, Pasadena, California, USA.
- ^{xxx} Also at Bingol University, Bingol, Turkey.
- ^{yyy} Also at Georgian Technical University, Tbilisi, Georgia.
- ^{zzz} Also at Sinop University, Sinop, Turkey.
- ^{aaaa} Also at Mimar Sinan University, Istanbul, Istanbul, Turkey.
- ^{bbbb} Also at Nanjing Normal University Department of Physics.
- ^{cccc} Also at Texas A&M University at Qatar, Doha, Qatar.
- ^{dddd} Also at Kyungpook National University, Daegu, Korea.
