#### Abstract

Controlling the formation of the desired product in the appropriate crystalline form is the fundamental breakthrough of crystal engineering. On that basis, the preferential formation between polymorphic forms, which are referred to as different assemblies achieved by changing the disposition or arrangement of the forming units within the crystalline structure, is one of the most challenging topics still to be understood. Herein, we have observed the formation of two concomitant polymorphs with general formula $\left\{\left[\mathrm{Hg}(\text { Pip })_{2}\left(4,4^{\prime}\right.\right.\right.$-bipy $\left.)\right] \cdot \mathrm{DMF}_{n}$ (P1A, P1B; Pip $=$ piperonylic acid; 4, $4^{\prime}$-bipy $=4,4^{\prime}$-bipyridine). Besides, $[\mathrm{Hg}-$ $(\operatorname{Pip})_{2}\left(4,4^{\prime}\right.$-bipy $\left.)\right]_{n}$ (2) has been achieved during the attempts to isolate these polymorphs. The selective synthesis of P1A and P1B  has been successfully achieved by changing the synthetic conditions. The formation of each polymorphic form has been ensured by unit cell measurements and decomposition temperature. The elucidation of their crystal structure revealed P1A and P1B as polymorphs, which originates from the $\mathrm{Hg}(\mathrm{II})$ cores and intermolecular associations, especially pinpointed by $\mathrm{Hg} \cdots \pi$ and $\pi \cdots \pi$ interactions. Density functional theory (DFT) calculations suggest that P1B, which shows $\mathrm{Hg}(\mathrm{II})$ geometries that are further from ideality, is more stable than P1A by $13 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}$ per $\left[\mathrm{Hg}(\operatorname{Pip})_{2}\left(4,4^{\prime}\right.\right.$-bipy $\left.)\right] \cdot$ DMF formula unit, and this larger stability of P1B arises mainly from metal $\cdots \pi$ and $\pi \cdots \pi$ interactions between chains. As a result, these structural modifications lead to significant variations of their solid-state photoluminescence.

## ■ INTRODUCTION

The rise of crystal engineering, triggered by the identification and understanding of the structural features in materials, enabled the prediction of crystal structures and, therefore, improved the ability to design products with desired chemical and physical properties by tuning their crystal structure. ${ }^{1,2}$ These structural modifications required understanding of molecular and supramolecular preferences and identifying interaction patterns. ${ }^{3,4}$ However, since crystallization is a kinetic process, metastable intermediates can be achieved as multiple local minima during the self-assembly of the ligands with the metal ion. ${ }^{5}$ These structures are mainly stabilized by the steric requirements of the linkers and by hydrogen bonds and noncovalent interactions inter alia $\pi \cdots \pi, \mathrm{C}-\mathrm{H} \cdots \mathrm{O}, \mathrm{C}-$ $\mathrm{H} \cdots \pi$ or the limited case of $\mathrm{Hg} \cdots \pi .^{6,7}$ Therefore, providing access to many potential structure accommodations. Not surprisingly, concomitant polymorphs can be formed within this landscape. ${ }^{8}$

Within this frame, slight modifications, intermediate variations, or major structural changes (polymorphism) throughout the entire crystal structure are promoted by factors such as time, ${ }^{9}$ temperature, ${ }^{10}$ solvent, ${ }^{11,12}$ or the introduction of templates, ${ }^{13}$ which influence both the nucleation rate and crystal growth. While the role of the solvent varies from filling voids and partaking in intermolecular interactions to being
coordinated to the metal center, ${ }^{14}$ temperature is a simple way to control the formation of polymorphic forms. Energetic data of organic polymorphs ${ }^{15}$ show that usually energy differences fall within the range of $0-10 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}$, but scarce data about relative energy calculation of coordination polymers have been found. ${ }^{16}$ Interestingly, these mere differences in the order of weak interactions are responsible for significant modification in the resulting properties. Recent photoluminescence studies of $\mathrm{Au}(\mathrm{I})$ coordination complexes have shown emission-dependent properties caused by slight structure differences after the absorption of guest solvent molecules. ${ }^{13}$ By this token, polymorphism in $\mathrm{Cu}(\mathrm{I})$ complexes evinced the impact of such structural differences in the photophysical properties. ${ }^{17}$
Although there is a large amount of polymorphism data about crystallization of organic salts ${ }^{18}$ and cocrystals ${ }^{19}$ of pharmaceutical interest, and despite the knowledge of polymorphs in discrete coordination complexes such as the

[^0]archetypal $\left[\mathrm{Pt}\left(2,2^{\prime}\right.\right.$-bipyridine $\left.) \mathrm{Cl}_{2}\right]$, ${ }^{20}$ there is a scarce number of structures bearing coordination polymers reported hitherto comprising $\mathrm{Cu}(\mathrm{I}),{ }^{2 \mathrm{I}-23} \mathrm{Ag}(\mathrm{I}),{ }^{14,24,25} \mathrm{Co}(\mathrm{II})$ and $\mathrm{Ni}(\mathrm{II}),{ }^{26-29}$ $\mathrm{Cd}(\mathrm{II}),{ }^{16,30}$ or $\mathrm{Pb}(\mathrm{II}) .{ }^{31}$ In this scenario, free rotation ligands can drive the formation of conformational polymorphs. ${ }^{25,28,32,33}$ Besides, $\mathrm{Hg}($ II $)$ as softer metal compared to Zn (II) and $\mathrm{Cd}(\mathrm{II})^{34}$ is capable of accommodating several distorted geometries and partake in weak intermolecular interactions. Thus, a combination of them can trigger the assembly of different arrangements. ${ }^{7,35}$
In pursuit of extending our knowledge on the structureproperty relationship of Hg (II) compounds, ${ }^{36,37}$ we have combined $\mathrm{Hg}(\mathrm{OAc})_{2}$, 1,3-benzodioxole-5-carboxylic acid (piperonylic acid, HPip) and the free rotational $4,4^{\prime}$-bipyridine ligand ( $4,4^{\prime}$-bipy). The synthesis performed at $95^{\circ} \mathrm{C}$ resulted in two concomitant polymorphs bearing the same zigzag onedimensional (1D) structure and accommodating guest $\mathrm{N}, \mathrm{N}$ dimethylformamide (DMF) molecules with general formula $\left\{\left[\mathrm{Hg}(\mathrm{Pip})_{2}\left(4,4^{\prime}\right.\right.\right.$-bipy $\left.)\right] \cdot \mathrm{DMF}_{n}$ (P1A and P1B). During the attempts to isolate each polymorphic forms, we recognized the formation of an additional zigzag 1D coordination polymer with formula $\left\{\left[\mathrm{Hg}(\operatorname{Pip})_{2}\left(4,4^{\prime} \text {-bipy }\right)\right]\right\}_{n}$ (2). All of them were characterized by analytical and spectroscopic techniques. In addition, periodic density functional theory (DFT) calculations have been performed to set the relative stabilities of both polymorphic forms and rationalize the origin of the different stability. Finally, these structural differences provoked dramatic variations in their solid-state photoluminescence.

## - EXPERIMENTAL SECTION

Chemical Risks. Hg (II) complexes are toxic, and any manipulation of the samples has to be carried out into the fume hood and wearing gloves.

Materials and General Details. Hg (II) acetate $\left(\mathrm{Hg}(\mathrm{OAc})_{2}\right)$, 1,3-benzodioxole-5-carboxylic acid (piperonylic acid, HPip), 4,4'bipyridine ( $4,4^{\prime}$-bipy) ligands, methanol ( MeOH ), $N, N$-dimethylformamide (DMF), acetic acid (HOAc), and diethyl ether ( $\mathrm{Et}_{2} \mathrm{O}$ ) as solvents were purchased from Sigma-Aldrich. The water used in the reactions was Milli-Q water. Deuterated dimethyl sulfoxide- $d_{6}$ (DMSO- $d_{6}$ ) was used for the NMR experiment and was purchased from Eurisotop. All of them were used without further purification. Reactions and manipulation were carried out in a Digitheat-TFT furnace (JP Selecta) using sealed vials under an autogenous pressure of DMF at $95^{\circ} \mathrm{C}$ for the synthesis of the mixture (P1A and P1B) and the isolation of either P1A or P1B. Compound 2 was synthesized in DMF at room temperature (RT) or both in MeOH and Milli-Q water at RT and $95{ }^{\circ} \mathrm{C}$. Powder X-ray diffraction (PXRD) patterns were measured with a PANalytical X'Pert PRO MPD $\theta / \theta$ powder diffractometer of 240 mm radius, in a configuration convergent beam with a focalizing mirror and a transmission geometry with flat samples sandwiched between low-absorbing films. A $\mathrm{Cu} \mathrm{K} \alpha$ radiation with $\lambda=1.5418 \AA$ was used ( 45 kW and 40 mA ). All of them were recorded from $2 \theta=5$ to $30^{\circ}$ with a step scan of $0.0263^{\circ}$ and a measuring time of 300 s per step. Thermal decomposition temperature (dT) was measured on a Stuart Melting Point Apparatus SMP30 with a heating ramp of $2.0^{\circ} \mathrm{C} \cdot \mathrm{min}^{-1}$ in a temperature range of $20-210^{\circ} \mathrm{C}$. Elemental analyses (C, H, N) were carried out on a Euro Vector 3100 instrument. Simultaneous thermogravimetric (TG)/ differential thermal analysis (DTA) determinations were performed with a Netzsch STA 409 instrument, using an aluminum oxide powder crucible and an oxide powder as a standard $\left(\mathrm{Al}_{2} \mathrm{O}_{3}\right.$, PerkinElmer 0419-0197) and heating at $5{ }^{\circ} \mathrm{C} \cdot \mathrm{min}^{-1}$ from 25 to 350 ${ }^{\circ} \mathrm{C}$, under nitrogen atmosphere with a flow rate of $80 \mathrm{~mL} \cdot \mathrm{~min}^{-1}$. The Fourier transform infrared-attenuated total reflection (FTIR-ATR) spectra were recorded on a PerkinElmer spectrometer, equipped with a universal attenuated total reflectance (ATR) accessory with
diamond window in the range of $4000-500 \mathrm{~cm}^{-1} \cdot{ }^{1} \mathrm{H},{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$, and distortionless enhancement by polarization transfer (DEPT)-135 NMR spectra were recorded on an NMR-FT Bruker360 MHz spectrometer in DMSO- $d_{6}$ solution at RT. All chemical shifts ( $\delta$ ) are given in ppm. Solid-state photoluminescence measurements were recorded using a Varian Cary Eclipse Fluorescence spectrophotometer between 500 and 660 nm . CIE 1931 chromaticity diagram was generated using Origin Pro 2019b software.

Synthesis of the Polymorphs Mixture: $\left\{\left[\mathrm{Hg}(\mathrm{Pip})_{2}\left(\mu-4,4^{\prime}-\right.\right.\right.$ bipy $\left.)\right]$. $D M F\}_{n}$ (P1A and P1B). DMF ( 2.5 mL ) was placed into a 10 mL vial and heated in a furnace until $95^{\circ} \mathrm{C}$. Once the temperature was reached, $4,4^{\prime}$-bipy ( $44.1 \mathrm{mg}, 0.282 \mathrm{mmol}$ ) and HPip ( $94.2 \mathrm{mg}, 0.567$ mmol ) were introduced. When the solution became transparent, $\mathrm{Hg}(\mathrm{OAc})_{2}(90.1 \mathrm{mg}, 0.283)$ was added and the suspension was sonicated for a minute until dissolution. The reaction was sealed and kept under autogenous pressure at $95^{\circ} \mathrm{C}$ for 45 min and then allowed to cool down out of the furnace for 1 h until $25^{\circ} \mathrm{C}$. After cooling, several prism-like colorless crystals were formed, filtered, and washed twice with 5 mL of cold $\mathrm{Et}_{2} \mathrm{O}$. Careful inspection of them revealed the presence of two different crystal sizes but sharing the same crystalline habit (the smaller ones were around $70 \%$, while the large ones were about $30 \%$ ). These single crystals were mechanically sorted for their X-ray crystal structure elucidation, revealing that the small crystals were P1A while the big crystals were P1B.

Synthesis of Compound $\left[\mathrm{Hg}(\mathrm{Pip})_{2}\left(\mu-4,4^{\prime}-\text { bipy }\right)\right]_{n}$ (2). To a solution of $\mathrm{Hg}(\mathrm{OAc})_{2}(100 \mathrm{mg}, 0.313 \mathrm{mmol})$ and HPip ( 105 mg , 0.631 mmol ) in DMF ( 3 mL ), a solution of $4,4^{\prime}$-bipy ( $49.0 \mathrm{mg}, 0.313$ $\mathrm{mmol})$ in DMF ( 2 mL ) was added dropwise under vigorous stirring. Immediately, a yellowish solid appeared. The reaction was stirred for 1 h . The solid obtained was filtered and washed with 10 mL of cold MeOH . Suitable crystals were obtained by slow diffusion of 5 mL of MeOH into 1 mL of the mother liquors for 5 days. The phase purity of the sample was confirmed by PXRD.

The synthesis of compound 2 was also achieved at RT and at $95^{\circ} \mathrm{C}$ using MeOH or Milli-Q water as a solvent.

 [ $\mathrm{O}-\mathrm{CH}_{2}-\mathrm{O}$ ].Synthesis of $\left\{\left[\mathrm{Hg}(\mathrm{Pip})_{2}\left(\mu-4,4^{\prime} \text {-bipy }\right)\right] \cdot D M F\right\}_{n}(P 1 A)$. DMF ( 5 mL ) and $\mathrm{HOAc}(10.9 \mu \mathrm{~L}, 0.190 \mathrm{mmol})$ were introduced into a 10 mL vial, sealed, and heated in a furnace until $95^{\circ} \mathrm{C}$. Once the temperature was reached, compound $2(65.3 \mathrm{mg}, 0.0950 \mathrm{mmol})$ was added and the mixture was sonicated for 1 min until a yellowish transparent solution was obtained. Then, the vial was sealed, kept at $95^{\circ} \mathrm{C}$ under an autogenous pressure for 45 min , and left to cool down slowly for 7 h until $25^{\circ} \mathrm{C}$ (Figure S1, Supporting Information). Suitable crystals of P1A were formed, collected, filtered off, and washed twice with 5 mL of cold $\mathrm{Et}_{2} \mathrm{O}$.

Yield: 42.8 mg (59\%). $\mathrm{dT}=192-193{ }^{\circ} \mathrm{C}$. FTIR-ATR (wavenumber, $\left.\mathrm{cm}^{-1}\right): 3098(\mathrm{w})-3012(\mathrm{w})[\nu(\mathrm{CH})]_{\mathrm{ar}}, 2895(\mathrm{w})[\nu(\mathrm{CH})]_{\mathrm{a}}$, $2780(\mathrm{w})[\nu(\mathrm{CH})]_{\mathrm{a}}, 1658(\mathrm{~s})[\nu(\mathrm{C}=\mathrm{O})]_{\mathrm{DMF}}, 1628(\mathrm{w})-1576(\mathrm{~m})$ $[\nu(\mathrm{C}=\mathrm{C} / \mathrm{C}=\mathrm{N})], 1542(\mathrm{~m})[\nu(\mathrm{COO})]_{\mathrm{as}}, 1503(\mathrm{~m})[\nu(\mathrm{C}=\mathrm{C} / \mathrm{C}=$ $\mathrm{N})], 1483(\mathrm{~m})[\nu(\mathrm{C}=\mathrm{C} / \mathrm{C}=\mathrm{N})], 1427(\mathrm{~m})[\nu(\mathrm{COO})]_{\mathrm{s}}, 1368(\mathrm{~s})-$ $1229(\mathrm{~s})[\delta(\mathrm{C}=\mathrm{C} / \mathrm{C}=\mathrm{N})], 1163(\mathrm{~m}), 1101(\mathrm{~m}), 1069(\mathrm{~m}), 1035(\mathrm{~s})$ $[\delta(\mathrm{C}-\mathrm{H})]_{\mathrm{ip}}, 1003(\mathrm{sh}), 935(\mathrm{~m}), 888(\mathrm{~m}), 861(\mathrm{w}), 820(\mathrm{~m})-771(\mathrm{~s})$ $[\delta(\mathrm{C}-\mathrm{H})]_{\text {oop }}, 719(\mathrm{~m}), 680(\mathrm{~m}), 660(\mathrm{~m}), 639(\mathrm{~m}), 629(\mathrm{~m}), 582(\mathrm{~m})$, 550(m), 538(m), 511(m).
Synthesis of $\left\{\left[\mathrm{Hg}(\mathrm{Pip})_{2}\left(\mu-4,4^{\prime}-b i p y\right)\right] \cdot D M F\right\}_{n}(P 1 B)$. The synthesis of P1B was performed following the same procedure as in the synthesis of P1A but without adding HOAc in the recrystallization of 2 ( $80.0 \mathrm{mg}, 0.117 \mathrm{mmol}$ ).
Yield: 64.9 mg ( $73 \%$ ). $\mathrm{dT}=198-199{ }^{\circ} \mathrm{C} .3098(\mathrm{w})-3012(\mathrm{w})$ $[\nu(\mathrm{CH})]_{\mathrm{ar}}, 2894(\mathrm{w})[\nu(\mathrm{CH})]_{\mathrm{a}}, 2786(\mathrm{w})[\nu(\mathrm{CH})]_{\mathrm{a}}, 1658(\mathrm{~s})[\nu(\mathrm{C}=$ O) $]_{\mathrm{DMF}}, 1628(\mathrm{w})-1578(\mathrm{~m}) \quad[\nu(\mathrm{C}=\mathrm{C} / \mathrm{C}=\mathrm{N})], 1540(\mathrm{~m}) \quad[\nu-$
$(\mathrm{COO})]_{\mathrm{as}}, 1504(\mathrm{~m})-1453(\mathrm{~m}) \quad[\nu(\mathrm{C}=\mathrm{C} / \mathrm{C}=\mathrm{N})], 1428(\mathrm{~m}) \quad[\nu-$ $(\mathrm{COO})]_{\mathrm{s}}, 1419(\mathrm{~m}), 1367(\mathrm{~s})-1230(\mathrm{~s}) \quad[\delta(\mathrm{C}=\mathrm{C} / \mathrm{C}=\mathrm{N})]$, $1163(\mathrm{~m}), 1101(\mathrm{~m}), 1070(\mathrm{~m}), 1036(\mathrm{~s})[\delta(\mathrm{C}-\mathrm{H})]_{\mathrm{ip}}, 1006(\mathrm{sh})$, $935(\mathrm{~m}), 920(\mathrm{~m}), 887(\mathrm{~m}), 866(\mathrm{w}), 819(\mathrm{~m})-769(\mathrm{~s})[\delta(\mathrm{C}-\mathrm{H})]_{\text {oop }}$, $720(\mathrm{~m}), 680(\mathrm{~m}), 661(\mathrm{~m}), 637(\mathrm{~m}), 630(\mathrm{~m}), 582(\mathrm{~m}), 554(\mathrm{~m})$, 536(m).

X-ray Crystallographic Data and Structural Analysis. Colorless prism-like P1A, P1B, and 2 specimens were used for the X-ray crystallographic analysis. The X-ray intensity data were measured on a D8 Venture system equipped with a multilayer monochromator and a Mo microfocus ( $\lambda=0.71073 \AA$ ). For P1A, P1B, and 2 the frames were integrated with the Bruker SAINT software package, using a narrow-frame algorithm. For P1A, the integration of the data using a triclinic unit cell yielded a total of 8231 reflections to a maximum $\theta$ value of $30.60^{\circ}$ ( $0.70 \AA$ resolution), of which 8231 were independent (average redundancy 1.000, completeness $=99.0 \%, R_{\text {int }}=18.28 \%, R_{\text {sig }}$ $=17.88 \%)$ and $3761(45.69 \%)$ were greater than $2 \sigma\left(|F|^{2}\right)$. For P1B, the integration of the data using a triclinic unit cell yielded a total of 216059 reflections to a maximum $\theta$ value of $30.55^{\circ}$ ( $0.70 \AA$ resolution), of which 33014 were independent (average redundancy 6.544, completeness $\left.=99.9 \%, R_{\text {int }}=5.74 \%, R_{\text {sig }}=3.96 \%\right)$ and 26560 ( $80.45 \%$ ) were greater than $2 \sigma\left(|F|^{2}\right)$. For 2, the integration of the data using a monoclinic unit cell yielded a total of 3368 reflections to a maximum $\theta$ value of $30.36^{\circ}$ ( $0.70 \AA$ resolution), of which 3368 were independent (average redundancy 1.000, completeness $=97.3 \%, R_{\text {int }}$ $\left.=4.05, R_{\text {sig }}=2.99 \%\right)$ and $3237(96.11 \%)$ were greater than $2 \sigma\left(|F|^{2}\right)$.
The structures were solved and refined using the Bruker SHELXTL Software Package (version-2018/3). ${ }^{38}$ For P1A, the final anisotropic

full-matrix least-squares refinement on $|F|^{2}$ with 330 variables converged at $R_{1}=4.58 \%$, for the observed data and $\mathrm{w} R_{2}=12.50 \%$ for all data. For P1B, the final anisotropic full-matrix least-squares refinement on $|F|^{2}$ with 1556 variables converged at $R_{1}=2.95 \%$, for the observed data and $w R_{2}=6.80 \%$ for all data. For 2, the final anisotropic full-matrix least-squares refinement on $|F|^{2}$ with 168 variables converged at $R_{1}=2.18 \%$, for the observed data and $\mathrm{w} R_{2}=$ $5.43 \%$ for all data. For P1A, P1B, and 2, the final cell constants and volume are based upon the refinement of the XYZ-centroids of reflections above $20 \sigma(I)$. Data were corrected for absorption effects using the multiscan method (SADABS). Crystal data and relevant details of structure refinement for compounds P1A, P1B, and 2 are reported in Table 1. Selected bond lengths, angles, and intermolecular interactions of P1A are listed in Table 2. Bond lengths, angles, and intermolecular interactions of P1B are shown in Tables 3-5, respectively. Bond lengths, angles, and intermolecular interactions of 2 are listed in Table 6.

The geometry evaluation of the three complexes has been performed using version 2.1 of $\mathrm{SHAPE}^{39}$ software, which is based on the low continuous-shape measure (CShM) value S. ${ }^{40}$ The corresponding atomic coordinates have been directly extracted from the .cif data. Hirshfeld surfaces with their 2D fingerprint plots have been generated using CrystalExplorer 17.5.41 The essential interactions have been divided into $\mathrm{O} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{O}, \mathrm{C} \cdots \mathrm{C}$ and those involving Hg (II).

Complete information about the crystal structure and molecular geometry is available in .cif format and deposited in the CCDC. CCDC numbers 2101056-2101058 contain the supporting data of this paper. Molecular graphics were generated using Mercury (version 4.3.1) ${ }^{42}$ with POV-Ray Package (version 3.7). ${ }^{43}$ Color codes for molecular graphics: light slate blue ( N ), suva gray ( C ), white ( H ), lavender gray ( Hg ), and red ( O ).

Computational Details. DFT calculations of P1A and P1B were carried out using the VASP code. ${ }^{44,45}$ Geometry optimizations were performed at the PBE-D2 level of theory ${ }^{46,47}$ assuming a P1 space

group and keeping the unit cell parameters to those determined by single-crystal X-ray diffraction (SC-XRD). With the aim of analyzing the suitability of the D2 Grimme's empirical correction, we compared

Scheme 1. Outline of the Formation of the Mixture (P1A and P1B) and 2 and the Isolation of P1A and P1B

Scheme 2. Optical Microphotographs of Single Crystals of P1A, P1B, and 2 from the Synthesis of the Mixture or Achieved by Recrystallization of $2^{a}$

${ }^{a}$ Inset: P1A and P1B Mixture.
the relative stability of P1B and P1A (in terms of potential energy per $\left[\mathrm{Hg}(\mathrm{Pip})_{2}\left(4,4^{\prime}\right.\right.$-bipy $\left.)\right] \cdot$ DMF unit formula) with PBE-D2, PBE-D3 and PBE-D*, a modification of the D2 Grimme's empirical term suggested to be more suitable for the modeling of molecular crystals. ${ }^{48}$ Results are reported in Table S1 in the Supporting Information and show that all Grimme's correction leads to a preference for the P1B polymorph and the differences between the three methods are small ( $5.5 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}$ ). Moreover, according to the literature, PBE-D3 is accurate enough for modeling molecular crystals ${ }^{49,50}$ and, indeed, it has been even used to compute reference values for the validation of less computationally demanding approaches. ${ }^{51}$ Ionic cores were described with the projector augmented wave (PAW) pseudopotentials. ${ }^{52,53}$ The valence electrons were represented through a plane-wave basis set with a kinetic energy cutoff of 600 eV . Since cell size and the number of Hg (II) units in the cell differs for P1A and P1B, the Brillouin zone was sampled with a different Monkhorst-Pack $K$-point mesh in each case, i.e., $(4 \times 4 \times 4)$ and $(1 \times 1 \times 1)$ for $\mathbf{P 1 A}$ and $\mathbf{P 1 B}$, respectively.

With the aim of getting further insights into the relative stability of the two polymorphs, we performed an energy partitioning scheme decomposing the association energy $(E)$ between two metal dimers of vicinal chains in two terms: (i) the energy cost to distort the dimers
from the optimal geometry of a hypothetical isolated fragment $\left(E_{\text {DIS }}\right)$ and (ii) the pure interaction energy ( $E_{\text {INT }}$ ) between the already distorted fragments (eq 1).

$$
\begin{equation*}
E=E_{\mathrm{DIS}(1)}+E_{\mathrm{DIS}(2)}+E_{\mathrm{INT}} \tag{1}
\end{equation*}
$$

These energy partition schemes are standard in computational chemistry and examples where they have been applied with success can be found in the literature. ${ }^{54,55}$ This analysis was made with molecular calculations that were performed at the same PBE-D2 level of theory and using Gaussian 16 package. ${ }^{56}$ Main group elements and valence electrons of $\mathrm{Hg}(\mathrm{II})$ were represented with the Pople 6$31+\mathrm{G}(\mathrm{d}, \mathrm{p})^{57,58}$ and Dunning's aug-cc-pVDZ ${ }^{59}$ Gaussian-type basis sets, respectively. The Hg (II) core was taken into account with the pseudopotential associated with aug-cc-pVDZ basis set. ${ }^{60}$

## RESULTS AND DISCUSSION

Formation of P1A, P1B, and 2. From the reaction of $\mathrm{Hg}(\mathrm{OAc})_{2}$, HPip and $4,4^{\prime}$-bipy in DMF as a solvent, three different crystalline products, namely, $\left\{\left[\mathrm{Hg}(\mathrm{Pip})_{2}\left(\mu-4,4^{\prime}-\right.\right.\right.$ bipy $)] \cdot \mathrm{DMF}\}_{n}(\mathbf{P 1 A}$ and P1B $)$ and $\left[\mathrm{Hg}(\operatorname{Pip})_{2}\left(\mu-4,4^{\prime} \text {-bipy }\right)\right]_{n}$

Figure 1. Comparative diffractograms from top to bottom: singlecrystal (SC) XRD pattern of P1B, PXRD of bulk P1B, PXRD of P1B after heating at $60^{\circ} \mathrm{C}$ for 8 h, PXRD of bulk P1B after heating at 60 ${ }^{\circ} \mathrm{C}$ for 24 h , and SC-XRD of 2.

Figure 2. Time-dependent FTIR-ATR spectra of P1B as of heating at $60{ }^{\circ} \mathrm{C}$. From top to bottom, $t_{0}=$ as-synthesized P1B; $t_{1}=$ after 1 h 30 $\mathrm{min} ; t_{2}=$ after $12 \mathrm{~h} ; t_{3}=$ after 19 h . The regions in which significant variations of the spectra occur have been highlighted in light green.
(2) have been isolated (Scheme 1) depending on the synthetic conditions.
The concomitant crystallization of P1A and P1B was observed when the reaction was performed in DMF at $95{ }^{\circ} \mathrm{C}$. Cooling down of the saturated solution for 1 h resulted in a crystals mixture of P1A and P1B. The main difference between both crystals at first sight is the size, being P1B larger than P1A. Instead, the formation of 2 is achieved at RT in DMF, MeOH , and Milli-Q water or also at $95{ }^{\circ} \mathrm{C}$ in MeOH and Milli-Q water. The different formation of the mixture P1A and P1B or 2 could rely on the different solubility of the final complexes under the reaction conditions. Compound 2 rapidly precipitates as a yellow powder when the reaction is performed at RT in DMF, while it is soluble at $95^{\circ} \mathrm{C}$. We have performed the reaction in a temperature range of $25-115^{\circ} \mathrm{C}$, once every $10{ }^{\circ} \mathrm{C}$ and the complete dissolution and formation of the
polymorphs is only observed as of $75{ }^{\circ} \mathrm{C}$ and rapidly precipitates as temperature drops. Over $105{ }^{\circ} \mathrm{C}$, complexes start to decompose. Their low solubility seems to facilitate the crystallization of different polymorphic intermediates, which suddenly nucleated and grew as temperature dropped. ${ }^{9}$ Therefore, temperature and thereby solubility are the key factors to the formation of the polymorphic mixture.

The isolation of polymorphic forms being initially found to concomitantly crystallize as a mixture has been one of the pillars of crystal engineering. However, to attain the proper conditions to reach the target crystal form is often intricated. In this scenario, one of the forms usually tends to be less stable and, hence, more complicated to be achieved. ${ }^{16}$ The ability of the linkers to arrange into different polymorphic forms relies on directing factors inter alia time, temperature, concentration, solvent, or additional anions during the crystallization step. ${ }^{12}$ Therefore, we modified the synthetic conditions trying to isolate P1A and P1B. These polymorphs were synthesized as single crystals by changing concentration, time, and temperature or adding HOAc to identify the formation of the polymorphs. After the initially found concomitant formation of P1A and P1B (Scheme 2), the isolation of P1B has been accomplished by recrystallization of 2 in DMF at $95{ }^{\circ} \mathrm{C}$ and slow cooling down for 7 h . The recrystallization of 2 to achieve P1B has been performed in a concentration range of $1.1 \times$ $10^{-3}-2.5 \times 10^{-2} \mathrm{M}$, from which the optimal conditions to crystallize P1B were found to be between $1.0 \times 10^{-2}$ and $2.5 \times$ $10^{-2} \mathrm{M}$. It is worth mentioning that P1B was formed regardless of the concentration while the formation of P1A was not observed. Since the initial reaction starting from $\mathrm{Hg}(\mathrm{OAc})_{2}$ resulted in the mixture of P1A and P1B, with P1A being the predominant form, we added equivalent amounts of HOAc to incorporate $\mathrm{OAc}^{-}$anions during the recrystallization of 2 in DMF at $95{ }^{\circ} \mathrm{C}$. Interestingly, the addition of the $\mathrm{OAc}^{-}$anions drove the formation of P1A (Scheme 2). All of those syntheses were examined by several single-crystal X-ray diffraction analyses to determine their unit cell parameters, which are markedly different between P1A and P1B. In addition, the unit cell of crystals previously measured was redetermined after up to 3 weeks and no interconversion between P1A and P1B was observed.

Some of the unit cell parameters measured are listed in Table S2, Supporting Information. The formation of each polymorphic form has been traced by single-crystal X-ray diffraction (SC-XRD), and the phase purity of 2 was confirmed by powder X-ray diffraction (PXRD) (Figure S2, Supporting Information). We also provide the PXRD pattern of P1B, confirmed by unit cell measurements, to ensure the absence of 2 in the sample (Figure S3, Supporting Information). The interconversion between P1B and 2 was followed by PXRD (Figure 1).

General Characterization. The three compounds were characterized by decomposition temperature (dT), elemental analysis (EA), FTIR-ATR and ${ }^{1} \mathrm{H}$ NMR spectroscopies, TG/ DTA, and single-crystal X-ray diffraction. Compound 2 was characterized by ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ and DEPT-135 NMR spectroscopies. In addition, the solid-state photoluminescence of the three complexes has been recorded.

We have recorded the FTIR-ATR spectra of P1A and P1B, P1A, P1B, and 2. The FTIR-ATR spectrum of the mixture of P1A and P1B is a combination of the spectra of the isolated products. The absence of bands in all of the FTIR-ATR spectra between 2630 and $2518 \mathrm{~cm}^{-1}$, attributable to hydrogen-

Figure 3. One-dimensional polymeric chains of (a)P1A, (b) P1B, and (c) 2. Insets: sequence of the different Hg (II) cores for each compound.
bonded $\nu(\mathrm{O}-\mathrm{H})_{\text {HPip }}$ and at $1667 \mathrm{~cm}^{-1}$ from $\nu(\mathrm{C}=\mathrm{O})_{\text {HPip }}$, indicates the deprotonation of the HPip ligand. The corresponding carboxylate bands appear at $1542 \mathrm{~cm}^{-1}$ (P1A), $1540 \mathrm{~cm}^{-1}$ (P1B), or $1560 \mathrm{~cm}^{-1}$ (2) for $\nu_{\text {as }}$ (COO) and at $1427 \mathrm{~cm}^{-1}$ (P1A), $1428 \mathrm{~cm}^{-1}$ (P1B), or $1430 \mathrm{~cm}^{-1}$ (2) for $\nu_{s}(\mathrm{COO})$ (Figures S4-S9, Supporting Information). The difference between these bands $\left(\Delta=\nu_{\mathrm{as}}(\mathrm{COO})-\nu_{\mathrm{s}}(\mathrm{COO})\right)$ reveals the coordination modes of the carboxylate linkers: ${ }^{61}$ $115 \mathrm{~cm}^{-1}$ (P1A), $112 \mathrm{~cm}^{-1}$ (P1B), and $130 \mathrm{~cm}^{-1}$ (2), suggesting bidentate chelate $\left(\mu_{1}-\eta^{2}\right)$ coordination mode in the three compounds. In addition, the spectra of P1A and P1B show a characteristic peak at $1658 \mathrm{~cm}^{-1}$ corresponding to the
$\nu(\mathrm{C}=\mathrm{O})_{\mathrm{DMF}}{ }^{6262}$ Additional bands from the aromatic rings have also been identified. ${ }^{63,64}$
The ${ }^{1} \mathrm{H}$ NMR spectra of P1A and P1B mixture and $\mathbf{2}$ have been recorded in DMSO- $d_{6}$ (Figures S10 and S11, Supporting Information). In the mixture of P1A and P1B, the presence of DMF is confirmed by signals at $7.94,2.88$, and 2.72 ppm . The spectra show aromatic signals from the Pip linkers between 7.58 and 6.95 ppm and the $-\mathrm{CH}_{2}-$ from the dioxole group at $6.10 \mathrm{ppm}(\mathbf{P} 1 \mathbf{A}+\mathbf{P 1 B})$ and 6.08 ppm (2). The two signals from the $4,4^{\prime}$-bipy appear between 8.77 and 7.89 ppm . The ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ and DEPT-135 NMR spectra of 2 display the carboxylate band at 169.07 ppm and the $-\mathrm{CH}_{2}-$ of the dioxole at 101.66 ppm . The remaining $C$ signals appear between

150.63 and 108.81 ppm . DEPT-135 experiment was required to ensure the correct assignation of the carbon atoms from the aromatic rings (Figure S12, Supporting Information).
TG-DTA determinations of the complexes were performed using 79.9 mg (P1A), 46.8 mg ( $\mathbf{P 1 B}$ ), or 81.2 mg (2). The TG analysis of 2 exhibits a flat profile without any mass loss up to $187{ }^{\circ} \mathrm{C}$. Besides, its decomposition temperature is set to 199 ${ }^{\circ} \mathrm{C}$ from the DTA data (Figure S13, Supporting Information). The TG analysis of P1A and P1B evidences the loss of a DMF molecule (P1A, exp. $7.30 \%$; calcd $9.60 \%$; P1B exp. $8.60 \%$; calcd $9.60 \%$ ) between 50 and $121^{\circ} \mathrm{C}(\mathrm{P} 1 \mathrm{~A})$ or between 90 and $126^{\circ} \mathrm{C}(\mathrm{P} 1 \mathrm{~B})$, and no more thermal events were observed until decomposition, being stable up to $193{ }^{\circ} \mathrm{C}(\mathbf{P 1 A})$ or 199 ${ }^{\circ} \mathrm{C}$ (P1B). From these data, it seems that the release of DMF by heating is favored in P1A with respect to P1B (Figures S14 and S15, Supporting Information).

Interconversion between P1A, P1B, and 2. All of the attempts to convert P1A into P1B and vice versa by applying temperature, unavoidably ended in their transformation into 2. Single crystals of P1A and P1B are stable under air exposure and no interconversion over time was observed. PXRD confirmed that in solid state, a single-crystal-to-single-crystal transformation between P1B and 2 gradually occurs upon
heating at $60{ }^{\circ} \mathrm{C}$ by losing the occluded DMF molecules (Figure 1).

Likewise, FTIR-ATR spectra of P1B evinced the loss of DMF molecules by the disappearance of the band at 1659 $\mathrm{cm}^{-1}$ attributed to the $v(\mathrm{C}=\mathrm{O})_{\mathrm{DMF}}$ (Figure 2). Once the transformation into 2 is achieved, the sample can be recrystallized using the conditions mentioned in the Experimental Section to synthesize single crystals of P1A or P1B. Therefore, polymorphs P1A and P1B seem to be monotropically related, and interconversion between them is only feasible via the formation of 2 , which is promoted by the loss of the DMF molecules and the consequent structural reorganization ending in 2.

Crystal Structures of P1A, P1B, and 2. Both polymorphs (P1A and P1B) crystallize in the triclinic $P \overline{1}$ space group, whereas 2 crystallizes in the monoclinic $C 2 / c$ space group. All of them present the same connectivity forming zigzag 1D polymeric structures, in which hexacoordinated Hg (II) centers bearing $\left[\mathrm{HgO}_{4} \mathrm{~N}_{2}\right]$ cores are assembled by bridging $4,4^{\prime}$-bipy ligands along the $[\overline{1} 01]$ (P1A) (Figure 3a), [2 11$]$ (P1B) (Figure 3b), or $[10 \overline{1}]$ (2) (Figure 3c) directions. The geometry of P1A and P1B is of distorted pentagonal pyramid (PPY-6), a seldom reported geometry present in a few

Figure 4. (a) Stacking of chains in P1A through (b) $\pi \cdots \pi$ and $\mathrm{Hg} \cdots \pi$ interactions or (c) between DMF and $4,4^{\prime}$-bipy by C-H $\cdots \mathrm{O}$ interactions. $\mathrm{Hg} \cdots \mathrm{C}$ interactions are highlighted in dark green and correspond to $\mathrm{Hg} 1 \cdots \mathrm{C} 12,3.52(1) \AA$, and $\mathrm{Hg} 1 \cdots \mathrm{C} 11,3.801(9) \AA . \mathrm{Hg} \cdots \mathrm{C}$ contact: $\mathrm{Hg} 1 \cdots \mathrm{C} 12$, $3.52(1) \AA$; $\mathrm{Hg} 1 \cdots \mathrm{C} 11,3.801(9) \AA . \mathrm{Cg}(2)=\mathrm{N} 2-\mathrm{C} 14-\mathrm{C} 15-\mathrm{C} 16-\mathrm{C} 17-\mathrm{C} 18$.
complexes and reserved to $\mathrm{Cd}^{65}$ or $\mathrm{Hg}^{66}$ when they are coordinated to linkers forcing geometric constrains. The geometric distortions have been evaluated by the low continuous-shape measure ( CSh ) value $S^{39,40}$ for the three potential geometries comprised in coordination number 6 (Table S3, Supporting Information). The resulting $S$ values agree with the better fitting of P1A $(S=5.748)$ and $\mathbf{P 1 B}(S$ : $7.550, \mathrm{Hg} 1 ; 6.450, \mathrm{Hg} 2 ; 7.466, \mathrm{Hg} 3 ; 5.863, \mathrm{Hg} 4$ ) with a PPY-6 and the pairing of 2 with a trigonal prismatic geometry (TPY$6, S=8.452$ ). P1A is assembled by planar $4,4^{\prime}$-bipy linkers $\left(\mathrm{Cg}(1)-\mathrm{Cg}(1)\right.$; torsion angle, $\left.\chi=1.8(11)^{\circ}\right)$ (Table 2), while P1B contains four Hg (II) centers connected by $4,4^{\prime}$-bipy ligands oriented with a $\chi$ up to $34.4(5)^{\circ}(\mathrm{Cg}(1)-\mathrm{Cg}(3), \chi=$ $8.0(5)^{\circ} ; \mathrm{Cg}(5)-\mathrm{Cg}(6), 3.5(5)^{\circ} ; \mathrm{Cg}(2)-\mathrm{Cg}(4), 34.4(5)^{\circ}$; $\left.\mathrm{Cg}(7)-\mathrm{Cg}(7), 0.1(6)^{\circ}\right)$ (Table 3). Compound 2 and P1A only have a single $\mathrm{Cg}(1)-\mathrm{Cg}(1) \chi$ value of $1.8(11)^{\circ}(\mathbf{P 1 A})$ and $0.1(3)^{\circ}(2)$.

Such an unusual geometry of the Hg (II) centers in the structure of P1A and P1B seems to be supported by the assembly of the polymeric chains in columns of stacked and coplanar $4,4^{\prime}$-bipy ligands. The cooperative $\pi \cdots \pi$ and $\mathrm{Hg} \cdots \pi$ interactions between the stacked $4,4^{\prime}$-bipy bring the chains closer, thus promoting the displacement of the carboxylate oxygen atoms from the Pip ligands toward the basal plane. The three complexes present similar bond lengths but markedly different bond angles. This is emphasized in the $\mathrm{N}-\mathrm{Hg}-\mathrm{N}$ bond angle being larger in P1A (104.3(2) ${ }^{\circ}$, Table 2) and P1B (104.2(1)-105.2(1) ${ }^{\circ}$, Table 4) with respect to $2\left(89.82(10)^{\circ}\right.$, Table 6).

P1A has one alternated cooperative interaction (Figure 4a), in which planar aromatic rings of $4,4^{\prime}$-bipy stacks at $3.736 \AA$ together with a $\mathrm{Hg} \cdots \pi$ interaction at $3.953 \AA$ (Figure 4 b ). The occluded DMF molecules are responsible for the coplanar orientation of $4,4^{\prime}$-bipy. They act as double $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ acceptors by associating with $4,4^{\prime}$-bipy through its four $m-\mathrm{H}$ atoms and fixing the two pyridyl rings (Table 2). As a consequence, the $4,4^{\prime}$-bipy ligands are coplanar preventing the formation of $\pi \cdots \pi$ interactions (Figure 4 c ).

P1B emulates the alternated sequence of interactions present in P1A but splitting each of the two patterns into three (Figure 5a).

It exhibits cooperative $\pi \cdots \pi$ and $\mathrm{Hg} \cdots \pi$ interactions involving $\mathrm{Hg} 1-\mathrm{Hg} 4$ (Figure 5b), Hg 1 and Hg 2 (Figure 5c), or Hg 3 and Hg 4 (Figure 5d) and three different $\mathrm{C}-\mathrm{H} \cdot \mathrm{O}$ interactions with the occluded DMF molecules (Figure 5e and Table 5). The $\mathrm{Hg}-\mathrm{C}_{\pi}$ contact value of $3.52(1) \AA$ in P1A and between 3.315 (4) and 3.641 (3) $\AA$ in P1B fall within the range of previously reported examples. ${ }^{67}$

By the same token, 2 assembles through $\pi \cdots \pi$ stacking but in a different manner. The piling of the chains is set in the alternate sequence $-\mathrm{Pip}-\mathrm{Pip}-4,4^{\prime}$-bipy- from perpendicular polymeric chains (Figure 6a). The aromatic rings of the Pip ligands stack at a $\mathrm{Cg}(1) \cdots \mathrm{Cg}(1)$ distance of $3.906(2) \AA$, whereas the interaction between Pip and $4,4^{\prime}$-bipy is of $\mathrm{Cg}(1) \cdots \mathrm{Cg}(2), 4.000(2) \AA$ (Table 6). This sequence is repeated twice within the unit cell along [220] (Figure 6b) or [220] (Figure 6c) directions.

These $\pi \cdots \pi$ interactions are supported by $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ interactions, but, unlike P1A and P1B, only two $m$-H of 4,4'-bipy pointing in opposite directions act as donors and interact with two coordinated carboxylate O atoms from parallel chains or with two dioxole O atoms from perpendicular chains.

Hirshfeld Surfaces and 2D Fingerprint Plots of P1A, P1B, and 2. Intermolecular interactions have been analyzed using CrystalExplorer $17.5^{41}$ by Hirshfeld Surface and 2D fingerprint plot analyses. The $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ interactions are highlighted as red spots in the lateral region of the Hirshfeld surfaces surrounding 4,4'-bipy ligands (Figure S16, Supporting Information). They are displayed in the 2D fingerprint plot as broad wings representing a total of $27.3 \%(\mathbf{P 1 A})$, between 27.0 and $28.0 \%$ (P1B) or $28.0 \%$ (2) of contact surface. The complementary interactions from the DMF molecules are found in the Supporting Information (Figure S17). Besides, $\pi \cdots \pi$ interactions are pointed as a central region in the 2 D fingerprint plot that corresponds to the $4.1 \%$ (P1A), between

Figure 5. Stacking of chains in P1B. Inset of $\pi \cdots \pi$ and $\mathrm{Hg} \cdots \pi$ interactions between (a) Hg 3 and Hg 4 ; (b) between Hg 1 and Hg 4 ; (c) Hg 1 and Hg 2 , and (d) Hg 3 and Hg 4 . (e) $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ interactions between pyridyl rings of $4,4^{\prime}$-bipy and DMF. Color codes: Hg 1 in yellow, Hg 2 in light green, Hg 3 in pink, and Hg 4 in light violet. Blue dashed lines indicate $\mathrm{Hg} \cdots \pi$ interactions in (b)-(d) and $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ in (e). $\pi \cdots \pi$ interactions are shown as light green dashed lines. $\mathrm{Hg} \cdots \mathrm{C}$ contacts: $\mathrm{Hg} 1 \cdots \mathrm{C} 75,3.641(3) \AA \AA ; \mathrm{Hg} 1 \cdots \mathrm{C} 76,3.769(3) \AA \AA_{;} \mathrm{Hg} 2 \cdots \mathrm{C} 23,3.628(3) \AA$ § $\mathrm{Hg} 2 \cdots \mathrm{C} 24,3.867(3) \AA$; $\mathrm{Hg} 3 \cdots$ C80, $3.396(3) ; \mathrm{Hg} 3 \cdots \mathrm{C} 81,3.816(3) ; \mathrm{Hg} 4 \cdots \mathrm{C} 28,3.315(4) \AA \AA ; \mathrm{Hg} 4 \cdots \mathrm{C} 27,3.737(3) \AA ̊ . \mathrm{Cg}(5)=\mathrm{N} 1-\mathrm{C} 17-\mathrm{C} 18-\mathrm{C} 19-\mathrm{C} 20-\mathrm{C} 21 ; \mathrm{Cg}(6)=\mathrm{N} 4-$ C48-C49-C50-C51-C52; Cg(7) = N5-C53-C54-C55-C56-C57; Cg(8) = N8-C100-C101-C102-C103-C104.
2.7 and $4.1 \%$ (P1B) or to a $14.1 \%$ (2) of C-C contact surface. It should be mentioned that despite the marked contribution from planar interactions in 2 , these aromatic rings are on the brink of effective $\pi \cdots \pi$ interactions. Finally, Hg (II) centers display a $3.4 \%$ (P1A) or between 3.0 and $3.4 \%$ (P1B) of contact surface toward the aromatic rings of $4,4^{\prime}$-bipy, while no contribution is observed in 2 (Table S4, Supporting Information).

DFT Calculations. With the aim of getting further insights into the relative stabilities of P1A and P1B polymorphs, we performed periodic DFT(PBE-D2) calculations with VASP code. ${ }^{44,45}$ The DFT optimized structures are close to those determined by single-crystal X-ray diffraction and particularly both the distorted pentagonal $\mathrm{Hg}(\mathrm{II})$ geometry and the distance between 1D zigzag polymeric chains are essentially
unchanged. This suggests that the present methodology accounts for the subtle van der Waals interactions. According to calculations, P1B is more stable than P1A by $13.4 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}$ per $\left[\mathrm{Hg}(\operatorname{Pip})_{2}\left(\mu-4,4^{\prime}\right.\right.$-bipy $\left.)\right] \cdot$ DMF formula unit. The energy difference between the two polymorphs is small, and this is in agreement with the formation of the two polymorphs and the possibility of selectively obtaining one of the two species. A partition energy scheme (Table 7) was performed to determine the origin for the preference for P1B. We decomposed the association energy ( $E$ ) between two metal dimers of vicinal chains (see Figure S18 for the model systems used in the partition scheme) in two terms: (i) distortion of the two dimers with respect to a hypothetical isolated dimer and (ii) the interaction energy between the distorted fragments (further details can be found in the Experimental Section).

| $\mathrm{Hg}(2)-\mathrm{Hg}(1) / \mathrm{Hg}(4)-\mathrm{Hg}(3)$ | -165.8 | 76.9 | 72.0 | -314.7 |

${ }^{a} E$ is the association energy, $E_{\operatorname{DIS}(1)}$ and $E_{\mathrm{DIS}(2)}$ are the energies required to distort the dimers to achieve the crystal structure, and $E_{\text {INT }}$ is the interaction energy between distorted fragments. All values are given in $\mathrm{kJ} \cdot \mathrm{mol}^{-1}$.

Figure 7. Solid-state emission spectra of complexes $2\left(\lambda_{\max -\mathrm{em}}=562\right.$ nm , bright gold), P1A ( $\lambda_{\text {max-em }}=565 \mathrm{~nm}$, mikado yellow), and P1B ( $\lambda_{\text {max-em }}=591 \mathrm{~nm}$, bright orange $)$. Inset of the samples under UV light of $\lambda=335 \mathrm{~nm}$ exposure.

Results indicate that the metal dimer distortion energies are all very similar (the largest variation is $4.9 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}$ ). In contrast, the interaction energy between the distorted fragments differs significantly, and it is larger for the vicinal chains of P1B. Consequently, the association between vicinal chains is 21.0 and $36.1 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}$ stronger for P1B than for P1A, and this suggests that the thermodynamic preference for P1B originates mainly from metal cation $\cdots \pi$ and $\pi \cdots \pi$ interactions, rather than the distortion arising from crystal packing. Remarkably, $\mathrm{Hg}(3)$ and $\operatorname{Hg}(4)$ centers, which present the less conventional coordination environment, show the smallest distortion energies and the highest interaction energies, thus suggesting that the final geometry around the metal center is tuned by several factors.

Photoluminescence Studies. Photoluminescence properties were recorded using single crystals of P1A, P1B, and 2 (Figure S19, Supporting Information). Under UV excitation of a pulse laser beam at $\lambda_{\text {exc }}=335 \mathrm{~nm}$, the samples display the corresponding emission spectra with emission maxima ( $\lambda_{\text {max-em }}$ ) located at $565 \mathrm{~nm}(\mathbf{P 1 A}), 591 \mathrm{~nm}$ (P1B), and 562 $\mathrm{nm}(2)$. The three spectra are composed of unstructured bands suggesting charge transfer transitions in character (Figure 7). The formation of the coordination polymers caused a bathochromic shift in emission compared to the free $4,4^{\prime}$ bipy ligand $\left(\lambda_{\text {max-em }}=401 \mathrm{~nm}\right) .{ }^{68}$ The emission of P1B is considerably blue-shifted, whereas P1A and 2 present closer emission maxima. All of them present moderate Stokes shifts of $12152 \mathrm{~cm}^{-1}$ (P1A), $12930 \mathrm{~cm}^{-1}$ (P1B), and $12057 \mathrm{~cm}^{-1}$ (2). As displayed in CIE 1931 chromaticity diagrams, both P1A and 2 display yellow emission colors ( $\lambda_{\text {max-em }}$ ), while P1B is reddish-orange at being irradiated under the selected $\lambda_{\text {exc }}$ (Figure S20, Supporting Information). A thorough study of the photophysical properties of biphenyl and related aromatic ligands ${ }^{69}$ evinced how molecular structure affects the shape and wavelength position of the emission spectrum. The case of biphenyl molecule remarks how the gain or loss of planarity modifies the absorption and emission properties. Since its increase is rendered to sharper spectra and better quantum yields, the loss of planarity tends to provoke larger stokes shifts.

Noteworthily strong $\pi \cdots \pi$ stacking as well as $\mathrm{Hg} \cdots \pi$ interactions open relaxation pathways to nonradiative decay processes and quench fluorescence. ${ }^{6}$ Therefore, the remarkable quenching in the emission of P1A and P1B compared to 2 could be explained by both the combination of intermolecular $\mathrm{Hg} \cdots \pi$ and $\pi \cdots \pi$ interactions, being the former only present in P1A and P1B. Besides, the aromatic rings in 2 are on the brink of $4.0 \AA$ for an effective $\pi \cdots \pi$ interaction (Table 6), whereas P1A and P1B have stacking of 4,4'-bipy at closer distances up to $3.736(\mathbf{P 1 A})$ or $3.632 \AA(\mathbf{P 1 B})$. By the same token, the larger stokes shift of P1B could be understood by considering the $4,4^{\prime}$-bipy torsion angles. Complexes P1A $\left(\chi=1.8(11)^{\circ}\right)$ and $2\left(\chi=0.1(3)^{\circ}\right)$ (Tables 2 and 6) present an adjacent $\lambda_{\text {max-em }}$ instead, P1B has $\chi$ between 0.1(6) and 34.4(5) ${ }^{\circ}$ (Table 3 ) with the consequent shift of emission up to 591 nm .

## - CONCLUSIONS

We have successfully isolated two polymorphic forms (P1A and P1B), initially found to be concomitantly formed, as well as their desolvated form 2. Interestingly, the separation between P1A and P1B was achieved by temperature or anion-template-dependent formation. Such control in polymorphism is scarce, especially when both forms tend to concomitantly crystallize. The crystal structures of the three compounds have been deeply analyzed revealing that $\mathrm{Hg}(\mathrm{II})$ is able to accommodate severe distortions and access to an uncommon distorted pentagonal pyramidal geometry. Those differences combined with the conformations of the $4,4^{\prime}$-bipy ligands resulted in significant variations of their photophysical properties. Besides, distortions in P1B not only modify the emission maxima, but, according to periodic-DFT calculations, they are counterbalanced leading to a more stable form as a consequence of stronger $\operatorname{Hg}(\mathrm{II}) \cdots \pi$ and $\pi \cdots \pi$ interactions. Therefore, this work contributes to the understanding of structure-property relationship in coordination polymers and provides an example of controlling the formation of concomitant polymorphs.
