Takehisa SHIRATSUCHI***

1. Introduction

The term "net accumulation of snow" used in this report is defined by the thickness of snow which was newly deposited onto or removed from the previous snow surface. JARE-12 (1971-1972) and JARE-13 (1972-1973) carried out their measurements of snow accumulation in Sôya Coast-Mizuho Plateau area, shown in Fig.A (folded map). Surface snow density in this area was almost ranged between 0.35 and 0.50g/cm³ (Endo and Fujiwara, 1973; Yamada, 1975; Naruse, 1975; Watanabe, 1975). Two kinds of stake measurement method were adopted; i.e. a "single-stake" method and a "stake-farm method.

Single-stake method: A number of stations, with one snow stake set up for each, were located at regular intervals (of several hundred meters-several kilometers) along an oversnow traverse route.

Stake-farm method: A number of snow stakes were set up in a regular configuration (e.g. rectangular lattice, cross shape and others) in a limited area.

The buried or exposed length of a stake by accumulation or erosion of snow was calculated from the difference of heights of the stake above the snow surface between two successive measurements: the height of a stake was always measured on its right-hand side, facing to the leeward of the prevailing wind with the accuracy of the centimeter, regardless of the microscopic feature of the snow surface, e.g. sastrugi and others. Old stakes set up by the previous expeditions were also measured, as long as the situation permitted.

Distribution of the stakes and the frequency of measurements were as follows:

* The Institute of Low Temperature Science, Hokkaido University, Sapporo.

** Water Research Institute, Nagoya University, Chikusa-ku, Nagoya.

*** Japan Meteorological Agency, Chiyoda-ku, Tokyo.

A. Single-stakes	Frequency of measurement	
Location	Feb.1971 - Jan.1972 (by JARE-12)	Feb.1972 - Jan.1973 (by JARE-13)
1. From S16 to Mizuho Camp along the routes S, H and Z	2 - 4 times	3 times
2. From S16 to S122 along the route S	1	1
3. From Mizuho Camp to S169 along the route X	1	-
4. From Mukai Rocks to S16	1	-

B. Stake-farm	Frequency of measurement	
Location	Feb.1971 - Jan.1972 (by JARE-12)	Feb.1972 - Jan.1973 (by JARE-13)
1. 12-stake farm and 9-stake line at Syowa Station	12 times	33 - 38 times
2. 36-stake farm at Mizuho Camp at S16, S30, H68, H180 } S122 and Z40 }	16 2 - 4	8 2 - 3
3. 81-stake farm at Mizuho Camp	established	1
4. 200-stake farm at Mizuho Camp S16 and S122	- -	6 3

2. Measurements

2.1 Net accumulation of snow by single-stake method

A stake at each station was denominated by its station number.

2.1.1. Along the traverse route from S16 to Mizuho Camp via routes S, H and Z

(a) From S16 to S30: Original stations of route S (S16, S17, S30) had been located at an interval of about 2km. To them JARE-12 in 1971 added three stations between S16 and S17, 5 stations between S17 and S18, and 6 stations between 2 adjacent original stations from S18 to S30 at regular intervals of about 300m; they resulted in the order of the stations along the route to be:

(S16) - S16-1 - S16-2 - S16-3 - (S17) - S17-1 - S17-2 - S17-5 -
(S18) - S18-1 - S18-2 - S18-6 - (S19) - S19-1 S29-6 - (S30),
where the station numbers in brackets indicate the original ones laid out in 1967 (JARE-8).

(b) From S30 to H306 (=S122) via route H: Each station was located at a interval of 300m for S30 - H61, and 500m for H61 - H306 (=S122), in 1971 (JARE-12).

(c) From Z0(=S122) to Mizuho Camp via route Z: Each station was located at an interval of 1km for Z0(=S122) - Z43 and Z70 - Z104, and 0.5km for Z43 - Z70, in 1970 (JARE-11) (Shimizu et al., 1972).

The result of the measurement is given in Tables 1a, 1b and 1c.

2.1.2. Along the traverse route from S16 to S122 via route S:

Each station was located at an interval of about 2km in 1967 (JARE-8).
The result of the measurement is given in Table 2.

2.1.3. Along the traverse route from Mizuho Camp to S169 via route X:

Each station was located at an interval of about 2km in 1970 (JARE-11).
The result of the measurement is given in Table 3.

2.1.4. Along the route from Mukai Rocks to S16:

Six stations, M1, M2, M6, were set up in 1971 (JARE-12) between Mukai Rocks and S16, as shown in Fig.1. As it was an active surface ablation zone of the ice sheet, a number of stakes set up in drill-holes of 2m in depth bored vertically at the ice sheet surface had fallen during summer. (Regarding the falling down of the stakes, the following process was presumed from observations: intensive radiation in summer heated considerably the stake (bamboo pole); the opening of the drill hole was melted and widened in a funnel shape by the warmed stake; the buoyancy of melt water filling up the drill hole caused the bamboo stake to be lifted up to an unstable position, and finally to fall down together with by wind action.)

To avoid such a trouble, a new method was designed for setting up a stake by use of a foam-styrene tube (a thermal insulator of a water pipe) of 1m in length and 5cm/2.5cm in outer/inner diameter. A vertical hole, 80 cm in

depth and 10 cm in diameter, was bored at the surface of the ice sheet by a SIPRE-type hand auger. The foam-styrene tube was placed vertically in it; the gap between the tube and the wall of the hole was packed tightly with crushed ice/snow; the upper part, about 20cm long, of the foam-styrene tube was exposed upright above the surface of the ice sheet. This work was done in August 1971. In January 1972, about 5 months after the setting, it was found that 5 tubes were in a measurable condition, while another one was found missing. The root of the tube has been fixed tightly in the hole with solid ice; the exposed part of the tube above the ice sheet surface had been bent along the surface; the exposed part of the tube was carefully returned to an upright position by a hand, and the height was measured. (It may be recommended that a rigid shaft be put in the bore of the tube so as to keep it standing straight.) The result of the measurement is given in Table 4.

At stations M4 and M5, the following was observed: When the snow stakes were set up on August 27, 1971, a snow surface at the end of the last summer was clearly identified inside the snow cover, at the levels of 27cm and 54cm below the present snow surface, respectively; the snow surface in question appeared as an iced one, caused by the soaking of meltwater by the end of the last summer and by subsequent refreezing. No iced layer is formed in the snow cover by ordinary snow accumulation after the end of summer. When the snow stakes were remeasured on January 26, 1972, water-soaked snow remained on the iced surface, which was accumulated after the end of the last summer; it had the thicknesses of 2cm and 47cm at M4 and M5. This fact indicates that the accumulation of snow is still positive by 2cm and 45cm in thickness at M4 and M5, respectively, after the end of the last summer. It is necessary to continue such an observation at least until the end of the summer in point, for the discussion of the annual accumulation of snow.

2.2. Net accumulation of snow by stake-farm method

2.2.1. Syowa Station

A snow accumulation area of Syowa Station was selected on the sea ice in the northeast of the station to avoid the topographical effect of East Ongul Island on the accumulation of snow. The accumulation area was composed of 2 parts as shown in Fig.2: a 12-stake farm consisting of stakes No.1, 2 ... and 12, in a rectangular lattice; a 9-stake line consisting of 9 stakes A, B, H and I on a straight line across Ongul Strait. The result of the measurement is given in Tables 5a, 5b and 5c.

2.2.2. 36-stake farm (6×6 stakes in a rectangular lattice with a lattice spacing of 20m, and with a side in parallel approximately to the direction of the prevailing wind, as shown in Fig.3; located at S16, S30, H68, H180, S122, Z40 and Mizuho Camp).

The snow stakes were denominated by the following rules (see Fig.3):

The columns of stakes in perpendicular to the prevailing wind were designated by Roman numerals I, II, III ... and VI, from right to left, in order, facing to the prevailing wind; the rows of stakes along the prevailing wind by Arabic numerals 1, 2, 3 and 6, from the windward to the leeward of the prevailing wind, in order. Each stake was defined by a combination of Roman and Arabic numeral, e.g. "III-4". The result of the measurement is given in Table 6.

2.2.3. 81-stake farm (9×9 stakes in a rectangular lattice with a lattice spacing of 500m, at Mizuho Camp)

The denomination of each snow stake of the farm was made by the similar rule to the 36-stake farm, I - IX for columns and 1 - 9 for rows, although the orientation of the 81-stake farm was slightly oblique to the direction of the prevailing wind, as shown in Fig.B (folded map). The result of the measurement is given in Table 7.

2.2.4. 200-stake farm (the basic configuration was 2 straight lines perpendicularly intersecting each other in the cross, T, or L shapes, with 100-stakes aligned on each line at an interval of 1m, the one line being approximately parallel to the direction of the prevailing wind and the other perpendicular to it, as shown in Figs. 4a, 4b and 4c; located at S16, S122 and Mizuho Camp).

The result of the measurement is given in Table 8.

Table 4. Accumulation and ablation at the surface of the coastal ice sheet in Sôya Coast: August 22, 1971 - January 26, 1972.

No.	Station Elevation above sea level (m)	Accumulation and ablation of the ice sheet surface (cm) (+ : accumulation; - : ablation)			
		from	to	(cm)	A*
M1	92	Aug.17, 1971	Jan. 26, 1972	-35 (ice)	—
M2	351	Aug.22	Jan. 26	-16 (ice)	—
M3	351	Aug.22	Jan. 26	-12 (ice)	—
M4	404	Aug.27	Jan. 26	-25(snow)	+2
M5	454	Aug.27	Jan. 26	- 7(snow)	+47

(ice), (snow): surface condition of the ice sheet on both Aug. 1971, and Jan. 1972.

A* : Net accumulation of snow from the end of the last summer to January 26, 1972.

Table 5a. Net accumulation of snow (cm) in Syowa Station area by 12-stake farm: March 20 - September 14, 1971. Value in (), 1st line dated March 20, 1971, indicates the thickness of the snow cover on the sea ice.
