## Chapter 2:

## ymmetric synthesis of first generation molecular motors based on indanones.

#### Abstract

A general enantioselective route to first generation molecular motors based on indanone precursors is described. Methoxy functionalized indanones could be prepared via a polyphosphoric acid (PPA) mediated reaction of which the regioselectivity could be controlled by the $\mathrm{P}_{2} \mathrm{O}_{5}$ content of the PPA employed. An enantioselective protonation of the silyl enol ethers of indanones by an $\mathrm{Au}(\mathrm{I}) \mathrm{BINAP}$ complex sets the stage for a diastereoselective McMurry coupling to give access to various functionalized overcrowded alkenes in good yields and good to excellent enantiomeric excess values.

## Chapter 2

### 2.1 Introduction

Light-driven molecular motors have been used in functional molecular systems either as unidirectional rotors or as chiral multi-state switches. Noteworthy examples of the latter include their use as photoswitchable catalysts, ${ }^{1}$ stereoselective anion binders ${ }^{2}$ or as switchable inducers in chirality amplification processes. ${ }^{3}$ Especially the first generation molecular motor with a xylene core (Figure 1c), has been a prominent building block for functional molecular systems. ${ }^{4}$ This compound, developed in 2008 and sometimes referred to as Mike's motor, benefits from a short synthesis, good photostationary state (PSS) ratios and a high thermal stability of the unstable cis isomer. ${ }^{5}$ These characteristics make this compound particularly suitable as chiral multi-state switch.

Chiral HPLC separations are normally used to obtain first generation molecular motors enantiomerically pure, as the asymmetric synthesis of first generation molecular motors proved to be problematic in the past. Ter Wiel et al. found in the synthesis that the conditions of the McMurry reaction, the key step to form the sterically hindered alkene, leads to complete racemization of the starting material (Scheme 1). ${ }^{7}$ In 2005, however, Harada et al. reported on the use of $\mathrm{TiCl}_{3}$ in combination with $\mathrm{LiAlH}_{4}$, allowing access to (unfunctionalized) first generation molecular motors as single enantiomers, albeit in a lower yield. ${ }^{8}$

Scheme 1: (a) Loss of stereochemical integrity during the McMurry reaction (b) McMurry reaction proceeding with retention of configuration. ${ }^{8}$

Considering that the development of functional systems based on molecular motors would greatly benefit from a simple method to access these building blocks and knowing that these compounds can be obtained via a McMurry coupling without loss of optical purity, the goal was set to develop a short synthesis of first generation xylene motors with different substitution patterns.

In order to accomplish this objective, a practical enantioselective synthesis of the precursor indanones was required. The enantioselective protonation of enol ethers seemed a promising strategy, as it is widely applicable and it does not necessitate the development of new synthetic routes to ketones of which only the racemic synthesis is known. ${ }^{9}$ Especially the gold catalyzed asymmetric protonation of silyl enol ethers (Scheme 2), developed by Toste et al. showed great promise with respect to the goal of this chapter as it was shown that this procedure can be applied for the enantioselective synthesis of 2-methyl-1-indanone. ${ }^{10}$

In this chapter, the asymmetric synthesis of various functionalized xylene first generation molecular motors is explored. Key questions which will be addressed are how to synthesize functionalized indanones, how general is Toste's methodology and what are the best conditions for the McMurry reaction in the synthesis of overcrowded alkenes.

## Synthesis of racemic indanones

Indanones 5 and 6 were synthesized from 2,5-dimethyl anisole and methacrylic acid using polyphosphoric acid (PPA) (Scheme 4). PPA is a mixture of oligomers of phosphoric acids with the general formula depicted in scheme 4 a . The overall composition of PPA is normally expressed in terms of its theoretical $\mathrm{P}_{2} \mathrm{O}_{5}$ and $\mathrm{H}_{2} \mathrm{O}$ content. ${ }^{9}$ It was found that the $\mathrm{P}_{2} \mathrm{O}_{5}$ content, had great effect on the regioselectivity of the reaction. Using PPA with a $\mathrm{P}_{2} \mathrm{O}_{5}$ content of $76 \%$, indanone 5 was obtained predominantly, while the use of PPA with $83 \% \mathrm{P}_{2} \mathrm{O}_{5}$ gave mostly indanone 6 (Scheme 4). To the best of the author's knowledge the effect of the PPA composition on the regioselectivity of these type of reactions was not described before. For that reason, a short investigation was conducted into its origin.

Scheme 4: (a) General structure of PPA. (b) Synthesis of indanone 5 and 6.

First of all, the difference in composition of PPA was apparent in the ${ }^{31} \mathrm{P}$ NMR spectrum. While PPA $\left(76 \% \mathrm{P}_{2} \mathrm{O}_{5}\right)$ consists mostly of $\mathrm{H}_{3} \mathrm{PO}_{4}$ and some diphosphoric acid, PPA $\left(83 \% \mathrm{P}_{2} \mathrm{O}_{5}\right)$ has a larger fraction of triphosphoric acid and larger oligomers. Analysis of a mixture consisting of $5 \mathrm{wt} \%$ methacrylic acid in PPA $\left(83 \% \mathrm{P}_{2} \mathrm{O}_{5}\right)$ at $80^{\circ} \mathrm{C}$ indicated the formation of several species, which were identified as phosphoric anhydrides of methacrylic acid. When PPA $\left(76 \% \mathrm{P}_{2} \mathrm{O}_{5}\right)$ was used, no mixed anhydride was observed. These results are also consistent with a literature report on the ratio of benzoic acid and its phosphoric anhydride in PPA of varying $\mathrm{P}_{2} \mathrm{O}_{5}$ content. ${ }^{11}$ Based on these results, the following mechanism is proposed (Scheme 5).

Scheme 5: Proposed mechanism for the switch in regioselectivity.

With PPA ( $83 \% \mathrm{P}_{2} \mathrm{O}_{5}$ ), the mixed anhydride of methacrylic acid is formed, which generates the corresponding acylium ion. The anisole performs a nucleophilic attack on this acylium ion to give the intermediate enone. After Nazarov cyclization, indanone 6 is obtained. In the case of PPA $\left(76 \% \mathrm{P}_{2} \mathrm{O}_{5}\right)$, it is proposed that the anisole will react through a competing pathway. The arene adds to the unsaturated carboxylic acid in a 1,4-fashion to afford the carboxylic acid. Subsequent Friedel-Crafts acylation will give indanone 5. The intermediates in these reactions were never observed, also when the reaction did not reach full conversion, indicating that the intramolecular reaction is faster than the intermolecular reaction, for both reaction pathways.

To examine the generality of the switch in regioselectivity depending on the $\mathrm{P}_{2} \mathrm{O}_{5}$ content of PPA, several other substrates were tested (Table 1). In all cases, it was found that the composition of PPA has an effect on the regioselectivity, although in some cases more pronounced than in others. The general trend is that PPA with a low $\mathrm{P}_{2} \mathrm{O}_{5}$ content promotes the formation of the indanone isomer having the electron-donating group meta to the carbonyl functionality, whereas PPA with a high $\mathrm{P}_{2} \mathrm{O}_{5}$ content favors the formation of the indanone with its electron-donating group ortho or para to the carbonyl functionality. Substitution at either the $\alpha$ or $\beta$ position of the unsaturated carboxylic acid disfavors formation of product I. The use of electron-poor benzene derivatives resulted in very low yields and was not investigated further.

Table 1: ${ }^{\text {a }}$ Condition A: $100{ }^{\circ} \mathrm{C}$, PPA $\left(76 \% \mathrm{P}_{2} \mathrm{O}_{5}\right)$; Condition B: $100{ }^{\circ} \mathrm{C}$, PPA $\left(83 \% \mathrm{P}_{2} \mathrm{O}_{5}\right) \cdot{ }^{\mathrm{b}}$ The regioisomer ratio was determined by analysis of the crude product with ${ }^{1} \mathrm{H}$ NMR spectroscopy.

From indanones 5 and 6, other functionalized indanones could be prepared in a straightforward way. The demethylation proceeded smoothly with $\mathrm{AlCl}_{3}$ at $100{ }^{\circ} \mathrm{C}$ in

toluene. At this point various oxygen protecting groups were installed using standard conditions (Scheme 6), in order to investigate the effect of this group on the subsequent enantioselective protonation.

Scheme 6: Synthesis of indanones 5, 6 and 17-24.

The other precursors, indanone 7 and $\mathbf{8}$ were prepared from 1,4-dibromo-2,5-dimethyl benzene (Scheme 7). Lithiation with $n-\mathrm{BuLi}$, followed by transmetalation with CuI , afforded the cuprate which added to ethyl methacrylate catalyzed by in situ generated TMSI. Cyclization of ethyl ester 25 using $\mathrm{H}_{2} \mathrm{SO}_{4}$ (96\%) afforded compound 7 in two steps with an of overall yield of $34 \%$ (based on dibromoxylene). The other regioisomer indanone 8 was prepared by Anouk Lubbe. Lithiation of 1,4-dibromo-2,5-dimethyl benzene with $n-\mathrm{BuLi}$, followed by the addition methacryl aldehyde gave the allylic alcohol. Subsequent oxidation and Nazarov cyclization afforded indanone 8.

Scheme 7: Synthesis of indanone 7 and 8.

## Enantioselective protonation of silyl enol ethers.

With the desired indanones in hand, the silyl enol ether formation and subsequent enantioselective protonation was investigated (Table 2). It was found that the electronic nature of the substituent $R^{1}$ and $R^{2}$ of the indanone has a large influence on the enantioselectivity of this reaction. The asymmetric protonation of the silyl enol ethers of indanones with bromo substituents proceeded with high selectivity, $97 \%$ enantiomer excess (ee) (entry 2 ) and $94 \%$ ee (entry 3 ), giving a significantly higher enrichment than observed for unsubstituted indanone 26, which gives $81 \%$ ee (entry 1). indanones with siloxy- and methoxy-substituents at the $R^{2}$ and especially the $R^{1}$ position (entries $4-6$ ) the selectivity was considerably lower ( $4-78 \%$ ee), probably due to a faster uncatalyzed background reaction of the silyl enol ether during the reaction. By changing to a more electron-withdrawing protective group of the phenolic group, like benzoate (entries 7 and 8 ) or carbonate (entries 9 and 10), high stereoselectivity (up to $98 \%$ ee) could be regained. However, the use of the 2,2,2-trichloro-ethoxycarbonyl (Troc) protective group (entries 9 and 10) resulted in low yields, due to the incompatibility of this moiety with LDA. The benzoate indanones (entires 7 and 8) were obtained in high yield but this protecting group could not be removed without racemizing the stereocenter. The indanones 19 and $\mathbf{2 0}$ were obtained in high optical purity by the deprotection of the Troc group of $\mathbf{2 3}$ and $\mathbf{2 4}$ using Zn and acetic acid, followed by the reprotection using TBSCl and imidazole.

## Synthesis of first generation molecular motors

With the enantioenriched ketones in hand, the next step was the formation of the sterically hindered double bond via the McMurry reaction. Using the condition of Harada et al. $\left(\mathrm{TiCl}_{3} / \mathrm{LiAlH}_{4}\right)$, the desired product $\mathbf{1}$ was obtained in $38 \%$ yield with an $E / Z$ ratio of 40:60. More surprisingly, the product was obtained with an enantiomeric

## Chapter 2

excess of $>98 \%$, starting from $89 \%$ ee for ketone 7. A rationalization for this observation is given further on. Unfortunately, alkene $\mathbf{1}$ was obtained as a mixture with dehalogenated byproducts, which were inseparable from the desired product. It has been reported in the literature that the reaction of $\mathrm{TiCl}_{3}$ with $\mathrm{LiAlH}_{4}$ results in the formation of a reactive titanium(II) hydride species. ${ }^{12}$ It is well possible that such a species is able to dehalogenate either the starting material or the product.

Scheme 8: McMurry coupling using $\mathrm{TiCl}_{3}$ and $\mathrm{LiAlH}_{4}$.

In an attempt to circumvent the formation of dehalogenated side products, the combination of $\mathrm{TiCl}_{3}$ and zinc was tried (Table 3). ${ }^{13}$ Fortunately, with these conditions no dehalogenation occurred and both bromo and TBS functionalized motors could be obtained in high yields and ee's. The Troc and the benzoate protecting group on the other hand were not compatible with the conditions of the McMurry reaction.

Also with Zn as reductant, a small increase of optical purity was observed, although less pronounced compared to the conditions with $\mathrm{LiAlH}_{4}$ as reductant. The absence of
racemization in the McMurry reaction using $\mathrm{TiCl}_{3} / \mathrm{Zn}$ is remarkable considering that the use of $\mathrm{TiCl}_{4} / \mathrm{Zn}$ has been reported to result in loss of optical purity. ${ }^{7}$ The standard procedure for the McMurry reaction (using $\mathrm{TiCl}_{4} / \mathrm{Zn}$ ) includes the initial reduction of $\mathrm{TiCl}_{4}$ to $\mathrm{TiCl}_{3}$ with Zn as first step, prior to the addition of the ketone. Thus both procedures essentially involve $\mathrm{Ti}(\mathrm{III})$ as reagent. Why racemization still occurred with the $\mathrm{TiCl}_{4} / \mathrm{Zn}$ protocol can be ascribed to an incomplete initial reduction step. Some $\mathrm{TiCl}_{4}$ remains which can, due to its Lewis acidic nature, racemize the substrate.

Another interesting aspect of the McMurry reactions described here is the enhancement of ee, which has not been reported before. It should be noted that the McMurry reaction in all the syntheses of first generation molecular motors is highly diastereoselective. Only the homocoupling products i.e. $R R$ and $S S$ are obtained. The formation of the $R S$ stereoisomer has never been observed. Based on this high stereoselectivity, the following mechanism is proposed. The treatment of a ketone with $\mathrm{TiCl}_{3} / \mathrm{Zn}$ results in the irreversible formation of a low-valent titanium(II) species (Scheme 9). ${ }^{12}$ When this reaction is performed on enantioenriched ketone, the concentration of the titanium(II) complex of e.g. the $R$ isomer is higher than for the $S$ complex, which will result in a different reaction rate for both dimerization reactions. Due to the longer reaction time required for homocoupling of the minor enantiomer, this isomer is more prone to side reactions such as the one leading to side product 28, which was obtained in all McMurry reactions using Zn and $\mathrm{TiCl}_{3}$. The overall result of these effects is that a relative larger amount of the minor enantiomer decomposes, with the consequence of an increased ee of the major product.

Scheme 9: Proposed mechanism for the increase of ee caused by the McMurry reaction.

## Chapter 2

In the case of a strong reductant such as $\mathrm{LiAlH}_{4}$, the increase in ee was larger than when the milder reductant Zn was used ( $89 \%$ ee $\rightarrow>98 \%$ versus $89 \%$ ee $\rightarrow 94 \%$ ee). It is hypothesized that under the harsher reaction conditions, the side reactions are faster and the effect of the concentration-dependency of the dimerization are therefore more pronounced.

### 2.3 Conclusion

In conclusion, an asymmetric synthesis of functionalized first generation molecular motors has been developed. The catalytic enantioselective protonation of silyl enol ethers by an in situ generated cationic $\mathrm{Au}(\mathrm{I}) \mathrm{BINAP}$ complex followed by a McMurry coupling with an ee amplification step gives access to the enantiomeric enriched first generation molecular motors. Especially the bromo substituted motors 1 and 2 can be obtained in high yield and enantioselectivity. This method however is not practical for the synthesis of oxygen functionalized motors, as it was found that the indanone precursors were difficult to obtain in high optical purity. The developed method have proven very valuable in the asymmetric synthesis of various molecular motors based on the first generation xylene motor. ${ }^{1 \mathrm{~b}, 1 \mathrm{cc}, 3 \mathrm{c}, 4 \mathrm{c}}$

## General Remarks

${ }^{1} \mathrm{H}$ NMR and ${ }^{13} \mathrm{C}$ NMR spectra were recorded on a Varian Unity Plus Varian-500 (500 and 125 MHz , respectively), Varian AMX400 ( 400 and 100 MHz , respectively) or a Varian VXR200-NMR spectrometer ( 200 MHz and 50 MHz , respectively) with $\mathrm{CDCl}_{3}$ or DMSO as solvent. Chemical shifts were determined relative to the residual solvent peaks $\left(\mathrm{CHCl}_{3}, \delta=7.26 \mathrm{ppm}\right.$ for ${ }^{1} \mathrm{H}$ NMR, $\delta=77.0 \mathrm{ppm}$ for ${ }^{13} \mathrm{C}$ NMR; DMSO, $\delta=2.50$ ppm for ${ }^{1} \mathrm{H}$ NMR, $\delta=39.5 \mathrm{ppm}$ for ${ }^{13} \mathrm{C}$ NMR). The following abbreviations are used to indicate signal multiplicity: s, singlet; d, doublet; t, triplet; q, quartet; m, multiplet; br, broad. Enantiomeric excesses were determined by chiral HPLC using a Shimadzu LC10ADVP HPLC equipped with a Shimadzu SPD-M10AVP diode array detector or by supercritical fluid chromatography (SFC), performed on a Thar Technologies, Inc. (Waters) Investigator II system. Optical rotations were measured on a Schmidt + Haensch polarimeter (Polartronic MH8) with a 10 cm cell (c given in $\mathrm{g} / 100 \mathrm{~mL}$ ) at $20^{\circ} \mathrm{C}$. Thin-layer chromatography (TLC) was performed on Merck TLC Silica gel 60

Kieselguhr F254. Flash chromatography was performed on silica gel Merck Type 9385 230-400 mesh or on a Reveleris X2 Flash Chromatography system. Mass spectra were recorded on a AEI-MS-902 mass spectrometer (EI + ) or a LTQ Orbitrap XL (ESI + ). All reagents were obtained from commercial sources and used as received without further purification. Polyphosphoric acid $\left(105 \% \mathrm{H}_{3} \mathrm{PO}_{4}\right.$ basis $\left(=76 \% \mathrm{P}_{2} \mathrm{O}_{5}\right)$ and $115 \% \mathrm{H}_{3} \mathrm{PO}_{4}$ basis $\left(=83 \% \mathrm{P}_{2} \mathrm{O}_{5}\right)$ ) was purchased from Sigma Aldrich. Solvents for extraction and chromatography were technical grade. All solvents used in reactions were freshly distilled from appropriate drying agents before use or obtained from a MBraun solvent purification system. All other reagents were used without further purification. All reactions were performed under anhydrous conditions in a $\mathrm{N}_{2}$ atmosphere, unless stated otherwise.

## General Procedure A

This reaction was performed under ambient conditions. A mechanically stirred solution of anisole ( $7.35 \mathrm{mmol}, 1.0 \mathrm{eq}$ ) and acid ( $14.7 \mathrm{mmol}, 2.0 \mathrm{eq}$ ) in $\sim 20 \mathrm{~g} \operatorname{PPA}\left(76 \% \mathrm{P}_{2} \mathrm{O}_{5}\right)$ was heated at $100^{\circ} \mathrm{C}$ for 4 h . The reaction mixture was quenched with ice and extracted with $\mathrm{Et}_{2} \mathrm{O}(3 \times 150 \mathrm{~mL})$ The organic layer was washed with a saturated solution of $\mathrm{NaHCO}_{3}$ (aq.) ( 200 mL ) and a 1 m solution of NaOH (aq.) ( 200 mL ) and dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$. The solvent was evaporated and the crude product purified by column chromatography $\left(\mathrm{SiO}_{2}\right.$, pentane/EtOAc).

## Chapter 2

## General Procedure C

To a solution of racemic ketone ( 1.00 equiv) in THF ( 0.1 m ) was added lithium diisopropylamide ( 1.05 equiv) at $-78{ }^{\circ} \mathrm{C}$. The reaction mixture was stirred for 2 h at $-78{ }^{\circ} \mathrm{C}$. After 2 h , trimethylsilyl chloride ( 1.20 equiv) was added to the reaction mixture. The reaction mixture was allowed to warm up to room temperature and stirred for an additional 2 h . Subsequently, the reaction mixture was cooled to $0{ }^{\circ} \mathrm{C}$ and hydrolyzed with saturated $\mathrm{NaHCO}_{3}$ (aq.), extracted with $\mathrm{Et}_{2} \mathrm{O}(3 \times 25 \mathrm{~mL})$, followed by brine, the organic layer was dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and concentrated in vacuo. The residue was filtered over a plug of silica and directly submitted to the next step without further purification. A solution of $(S)-\operatorname{BINAP}(\mathrm{AuCl})_{2}\left(0.006 \mathrm{M}\right.$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}, 0.03$ equiv) and a solution of $\mathrm{AgBF}_{4}$ ( 0.006 m in $\mathrm{EtOH}, 0.03$ equiv) were added at room temperature to a Schlenk flask. The reaction mixture was stirred for 45 min at room temperature, before cooling down to $0^{\circ} \mathrm{C}$. The catalyst solution was added to the silyl enol ether at $0^{\circ} \mathrm{C}$. The reaction mixture was allowed to warm up to room temperature and stirred overnight. The reaction mixture was hydrolyzed with saturated $\mathrm{NaHCO}_{3}$ (aq.), extracted with $\mathrm{Et}_{2} \mathrm{O}$, the organic layer was dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and concentrated in vacuo. The crude product was purified by column chromatography $\left(\mathrm{SiO}_{2}\right.$, pentane/EtOAc) to afford ( $R$ )-ketone.

## (R)-2,4,7-trimethyl-2,3-dihydro-1 $H$-inden-1-one (26)

The product was obtained according to General Procedure C as a colorless liquid ( $393 \mathrm{mg}, 2.26 \mathrm{mmol}, 85 \%$ over two steps) and $81 \%$ ee. Enantiomeric excess determined by chiral HPLC analysis, Chiralpak OJ-H ( $98 \% n$-heptane $/ 2 \% ~ i$-PrOH), $40{ }^{\circ} \mathrm{C}$, $0.5 \mathrm{~mL} / \mathrm{min}$, retention times (min) 12.1 (minor) and 12.6 (major); $[\alpha]_{\mathrm{D}}{ }^{20}=-39.0^{\circ}(c=$ 1.1, $\mathrm{CHCl}_{3}$ ); Spectroscopic data identical with those reported above.

## General Procedure D

Ketone ( 1.0 equiv), zinc powder ( 4.2 equiv) and $\mathrm{TiCl}_{3}$ ( 2.1 equiv) were suspended in THF $(0.04 \mathrm{~m})$ and heated at reflux for 96 h . After cooling down to room temperature the reaction mixture was filtered over celite and washed with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$. The filtrate was washed with a solution of $\mathrm{NH}_{4} \mathrm{Cl}$ (aq.), which was reextracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(3 \times 50 \mathrm{~mL})$ The combined organic layers were dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and concentrated in vacuo. The crude product was purified by column chromatography $\left(\mathrm{SiO}_{2}\right.$, pentane $\left./ \mathrm{Et}_{2} \mathrm{O}\right)$ to afford the coupling product as an $E / Z$-mixture.
