**Abstract**—The significant benefit of lock (or wait)-freedom for real-time systems is that by avoiding locks the potentials for deadlock and priority inversion are avoided. The lock-free algorithms often require the use of special atomic processor instructions such as CAS (compare and swap) or LL/SC (load linked/store conditional). However, many machine architectures support either CAS or LL/SC with restricted semantics. In this paper, we present a Practical lock-free implementation of the ideal semantics of LL/SC using only pointer-size CAS. To ensure our implementation is not flawed, we used the higher-order interactive theorem prover PVS for mechanical support.

## I. INTRODUCTION

Over the past two decades the research community has developed a body of knowledge concerning "Lock-Free" and "Wait-Free" algorithms and data structures. In contrast to algorithms that protect access to shared data with locks, lock-free and wait-free algorithms are specially designed to allow multiple threads to read and write shared data concurrently without corrupting it. The significant benefit of lock (or wait)-freedom for real-time systems is that by avoiding locks the potentials for deadlock and priority inversion are avoided.

In computer science, *non-blocking* synchronization ensures that threads competing for a shared resource do not have their execution indefinitely postponed by mutual exclusion. A non-blocking algorithm is *lock-free* if there is guaranteed system-wide progress; *wait-free* if there is also guaranteed per-thread progress. More formally, an algorithm is called *lock-free* if every step taken achieves global progress; an algorithm is called *wait-free* if every operation has a bound on the number of steps it will take before completing.

A number of researchers [3], [5], [7], [9], [15] have proposed techniques for designing lock-free implementations. The lock-free algorithms often require the use of special atomic processor instructions such as CAS (compare and swap) or LL/SC (load linked/store conditional). However, Current mainstream architectures support either CAS or LL/SC with restricted semantics (but not both), which are susceptible to the ABA problem [14].

The ideal semantics of the atomic primitives LL/SC are inherently immune to that problem. However, for practical architectural reasons, no processor architecture supports the ideal semantics of LL/SC. Designing efficient algorithms to

bridge the gap has been the subject of many researchers' interest. However, most of the research is focused on implementing only small LL/SC objects, whose value fits in a single machine word [4], [8], [9], [11].

In this paper, using only pointer-size CAS we present a Practical lock-free implementation of the ideal semantics of LL/SC objects (whose value does not have to fit in a single machine word) without causing ABA problem. To ensure our implementation is not flawed, we used the higher-order interactive theorem prover PVS [6] for mechanical support. All invariants as well as the simulation relation have been completely verified with PVS.

## II. PRELIMINARY

The machine architecture that we have in mind is based on modern shared-memory multiprocessors that can access a common shared address space in a heap. There can be several processes running on a single processor. Variables in shared context are visible to all processes running in associated parallel. Variables in private context are hidden from other processes.

We assume a universal set  $\mathcal{V}$  of typed variables, which is called the *vocabulary*. A state  $s$  is a type-consistent interpretation of  $\mathcal{V}$ , mapping variables  $v \in \mathcal{V}$  to values  $s[v]$ . We denote by  $\Sigma$  the set of all states. If  $\mathcal{C}$  is a command, we denote by  $\mathcal{C}_p$  the transition  $\mathcal{C}$  executed by process  $p$ , and  $s[\mathcal{C}_p]t$  indicates that in state  $s$  process  $p$  can do a step  $\mathcal{C}$  that establishes state  $t$ . When discussing the effect of a transition  $\mathcal{C}_p$  from state  $s$  to state  $t$  on a variable  $v$ , we abbreviate  $s[v]$  to  $v$  and  $t[v]$  to  $v'$ . We use the abbreviation  $Pres(V)$  for  $\bigwedge_{v \in V} (v' = v)$  to denote that all variables in the set  $V$  are preserved by the transition.

### A. The Semantics of Synchronization Primitives

Traditional multiprocessor architectures have included hardware support only for low level synchronization primitives such as CAS and LL/SC, while high level synchronization primitives such as locks, barriers, and condition variables have to be implemented in software.

CAS atomically compares the contents of a location with a value and, if they match, stores a new value at the location. The semantics of CAS is given by equivalent atomic statements

below. We use angular brackets  $\langle \dots \rangle$  to indicate atomic execution of the enclosed specification command.

```

proc CAS(ref X : Val; in old, new : Val) : Bool =
  ⟨ if X = old then X := new; return true
    else return false; fi ⟩

```

*LL* and *SC* are a pair of instructions, closely related to the CAS, and together implement an atomic Read/Write cycle. Instruction *LL* first reads the content of a memory location, say *X*, and marks it as “reserved” (not “locked”). If no other processor changes the content of *X* in between, the subsequent *SC* operation of the same process succeeds and modifies the value stored; otherwise it fails. The semantics of *LL* and *SC* are given by equivalent atomic statements below, where *me* is the process identifier of the acting process.

```

proc LL(in X : Val) : Val =
  ⟨ S.X := S.X ∪ {me}; return X; ⟩

```

```

proc SC(ref X : Val; in Y : Val) : bool =
  ⟨ if me ∈ S.X then
    S.X := ∅; X := Y; return true
    else return false; fi ⟩

```

### B. Refinement mappings

In practice, the specification of systems is concerned rather with externally visible behavior than computational feasibility. We assume that all levels of specifications under consideration have the same observable state space  $\Sigma_0$ , and are interpreted by their observation functions  $\Pi : \Sigma \rightarrow \Sigma_0$ . Every specification can be modeled as a four-tuple  $(\Sigma, \Pi, \Theta, \mathcal{N})$  where  $(\Sigma, \Theta, \mathcal{N})$  is the *transition system* [2].

A *refinement mapping* from a lower-level specification  $\mathcal{S}_c = (\Sigma_c, \Pi_c, \Theta_c, \mathcal{N}_c)$  to a higher-level specification  $\mathcal{S}_a = (\Sigma_a, \Pi_a, \Theta_a, \mathcal{N}_a)$ , written  $\phi : \mathcal{S}_c \sqsubseteq \mathcal{S}_a$ , is a mapping  $\phi : \Sigma_c \rightarrow \Sigma_a$  that satisfies:

- 1)  $\phi$  preserves the externally visible state component:  $\Pi_a \circ \phi = \Pi_c$ .
- 2)  $\phi$  is a *simulation*, denoted  $\phi : \mathcal{S}_c \preceq \mathcal{S}_a$ :
  - ①  $\phi$  takes initial states into initial states:  $\Theta_c \Rightarrow \Theta_a \circ \phi$ .
  - ②  $\mathcal{N}_c$  is mapped by  $\phi$  into a transition (possibly stuttering) allowed by  $\mathcal{N}_a$ :
 
$$\mathcal{Q} \wedge \mathcal{N}_c \Rightarrow \mathcal{N}_a \circ \phi$$
, where  $\mathcal{Q}$  is an invariant of  $\mathcal{S}_c$ .

Below we need to exploit the fact that the simulation only quantifies over all reachable states of the lower-level system, not all states. We therefore explicitly allow an invariant  $\mathcal{Q}$  in condition 2 ②. The following theorem is stated in [1].

**Theorem 1** *If there exists a refinement mapping from  $\mathcal{S}_c$  to  $\mathcal{S}_a$ , then  $\mathcal{S}_c$  implements  $\mathcal{S}_a$ .*

### III. THE LOCK-FREE IMPLEMENTATION OF LL/SC

Let us assume there are  $P (\geq 1)$  concurrently executing sequential processes. To distinguish private persistent variables of different processes, every persistent private variable name can be extended with the suffix “.” + “*process identifier*”. In

#### Constant

$P$  = number of processes;  
 $N$  = number of shared variables;

#### Shared variable

Node: **array** [1... $N$ ] **of** Val;  
 $S$ : **array** [1... $N$ ] **of** Set;

#### Private variable

$pc$ :  $\{a_1; a_2\}$ ;  
 $me$ : ProcID;

**proc** LL(**in**  $x : 1 \dots N$ ) : Val =

$a_1$ :  $\langle S[x] := S[x] \cup \{me\}$ ; **return** Node[ $x$ ];  $\rangle$

**proc** SC(**in**  $x : 1 \dots N$ ;  $Y : \text{Val}$ ) : Bool =

$a_2$ :  $\langle$  **if**  $me \in S[x]$  **then**

$S[x] := \emptyset$ ; Node[ $x$ ] :=  $Y$ ; **return** true

**else return** false; **fi**  $\rangle$

#### Initial conditions

$\Theta_a$ :  $\forall p : 1 \dots P : pc.p = a_1 \vee pc.p = a_2$

Fig. 1. The Specification  $\mathcal{S}_a$  of LL/SC

particular,  $pc.q$  is the program location of process  $q$ , it ranges over all defined integer labels.

The specification  $\mathcal{S}_a$  of LL/SC can then be given as shown in Fig. 1. In the specification, we model the Node as an array of the  $N$  shared variables in the heap under consideration, which can be of any type (e.g. Val). The indices of the Node are the addresses (or the pointers) to shared variables. We can thus simply regard the shared variable  $X$  (under consideration) as a synonym of an index of the Node, and its value is stored in Node[ $x$ ]. As before, the action enclosed by angular brackets  $\langle \dots \rangle$  is defined as atomic statement.

We now turn our attention to the lock-free implementation using only pointer-size CAS, which is given by the algorithm shown in Fig. 2. This lock-free implementation is inspired by our previous work [12].

In the lock-free implementation, the shared variable  $\text{indir}[x]$  acts as pointers to the shared node  $x$  under consideration (i.e., the shared variable), while  $\text{node}[mp_p]$  is taken as a “private” node of process  $p$  though it is declared publicly: other processes can read it but cannot modify it.

We need to ensure all indices of shared nodes and “private” nodes (declared in a public way) are mutually different. The basic idea to do this is to employ array  $\text{prot}$  to count the number of processes that are using an index for accessing a node, in such a way that the consistency of a node can be checked by its index: suppose process  $p$  first reads the index of node  $x$  to local variable  $m$  (see line  $c_{10}$  and line  $c_{22}$ ), then the consistency can be checked later by the predicate  $m = \text{indir}[x]$ .

In  $\mathcal{S}_c$ , LL/SC are taken as pairs of instructions, that together implement atomic read/write cycle. In the implementation, we therefore increment and decrement the corresponding counter (in array  $\text{prot}$ ) in the procedures of LL and SC, respectively. The increment of  $\text{prot}[m]$  (see line  $c_{14}$ ) is essential since it guarantees that the accessing node can not be taken as a private

### Constant

$P$  = number of processes;  
 $N$  = number of shared variables;  
 $K = N + 2P$ ;

### Shared variable

Node: **array**  $[1 \dots K]$  of Val;  
indir: **array**  $[1 \dots N]$  of  $1 \dots K$ ;  
prot: **array**  $[1 \dots K]$  of  $0 \dots K$ ;

### Private persistent variable

$pc$ :  $[c_{10} \dots c_{34}]$ ;  
 $mp$ :  $1 \dots K$ ;

**proc**  $LL$ (in  $x : 1 \dots N$ ) : Val =

```
loop
 $c_{10}$ :    $m := \text{indir}[x]$ ;
 $c_{12}$ :    $\text{mybuf} := \text{Node}[m]$ ;
 $c_{14}$ :    $\text{prot}[m] ++$ ;
 $c_{16}$ :   if  $m = \text{indir}[x]$  then
         $\text{return mybuf}$ ;
        else
 $c_{18}$ :    $\text{prot}[m] --$ ;
        fi;
```

**end**;

**proc**  $SC$ (in  $x : 1 \dots N$ ;  $Y : \text{Val}$ ) : Bool =

```
 $c_{20}$ :  $\text{Node}[mp] := Y$ 
loop
 $c_{22}$ :    $m := \text{indir}[x]$ ;
 $c_{24}$ :   if  $\text{CAS}(\text{indir}[x], m, mp)$  then
         $\text{prot}[m] --$ ;
 $c_{26}$ :   if  $\text{prot}[m] = 1$  then
 $c_{28}$ :    $mp := m$ ;
        else
 $c_{30}$ :    $\text{prot}[m] --$ ;
        repeat
            choose  $mp$  from  $1 \dots K$ 
 $c_{32}$ :   until  $\text{CAS}(\text{prot}[mp], 0, 1)$ 
        fi;
         $\text{return true}$ ;
        else
 $c_{34}$ :    $\text{prot}[m] --$ ;
         $\text{return false}$ ;
        fi;
```

**end**.

### Initial conditions

$\Theta_c$ :  $(\forall p : 1 \dots P : (pc.p = c_{10} \vee pc.p = c_{20})$   
 $\wedge \text{mybuf}_p = N+p)$   
 $\wedge (\forall i : 1 \dots N : \text{indir}[i] = i)$   
 $\wedge (\forall i : 1 \dots K : \text{prot}[i] = (i \leq N+P ? 1 : 0))$

Fig. 2. The Lock-free implementation  $\mathcal{S}_c$  of  $LL/SC$

node. The decrement of  $\text{prot}[m]$  (see lines  $c_{18}$ ,  $c_{26}$  and  $c_{30}$ ) is also important since otherwise the implementation will eventually run out of memory.

At line  $c_{24}$ , after  $\text{CAS}$  succeeds the “private” node with value  $Y$  serves as the shared node of  $x$ . If some other process

successfully updates a shared node (line  $c_{24}$ ) while an active process  $p$  is copying the shared node to its “private” node (see line  $c_{12}$ , process  $p$  will restart the loop, since its private view of the node is not consistent anymore.

During the read/write cycle. Decrement of  $\text{prot}[m]$  in line  $c_{26}$  is necessary since  $m$  does not refer a shared node when  $\text{CAS}$  in line  $c_{24}$  succeeds. When the check in line  $c_{28}$  finds that  $\text{prot}[m]$  equals 1, it means that only this process is hanging on that index, and the process can thus immediately treat that node as its private node. Otherwise, the previous shared node can not be served as a private node immediately when some process is still hanging on that node. Otherwise, interference may occur when the new “private” node is redirected to be a shared node again. Before the process starts to find an unused index for its private node, it needs to release the reading access to the node (see line  $c_{30}$ ). Right after the success of  $\text{CAS}$  at line  $c_{32}$ , the “private” node indexed by  $mp$  has been successfully chosen. When a new unused index, say  $mp$ , is chosen in line  $c_{32}$ , the process will set  $\text{prot}[mp]$  to 1 instead of 0. Therefore, no other process will regard that chosen “index” as an unused index and take that for its private use.

Guarded by  $\text{prot}$ , every “private” node for each process is now truly private since it does not even allow some other process to have a peep at its content. This means that the assignment of the “private” node is safe (see line  $c_{20}$ ), and it only needs to be executed once at the beginning of the procedure  $SC$ .

In the implementation  $\mathcal{S}_c$ , we introduce a constant  $K \geq N + 2P$  for the sizes of the arrays  $\text{Node}$  and  $\text{prot}$ . There is a trade-off between space and time that the user can choose: large  $K$  is faster when choose an unused index for a “private node” at line  $c_{32}$ , but requires more space.

## IV. CORRECTNESS

In this section we will prove that the concrete system  $\mathcal{S}_c$  implements the abstract system  $\mathcal{S}_a$ . Formally, like we did in [10], [14], we define

$$\begin{aligned} \Sigma_a &\triangleq (\text{Node}[1 \dots N], S) \times (pc, me, x, Y)^P \\ \Sigma_c &\triangleq (\text{Node}[1 \dots K], \text{indir}[1 \dots N], \\ &\quad \text{prot}[1 \dots K]) \times (pc, x, Y, mp, m, \text{mybuf})^P \\ \Pi_a(\Sigma_a) &\triangleq \text{Node}[1 \dots N] \\ \Pi_c(\Sigma_c) &\triangleq \text{node}[\text{indir}[1 \dots N]] \\ \mathcal{N}_a &\triangleq \mathcal{N}_{a_0} \vee \mathcal{N}_{a_1} \vee \mathcal{N}_{a_2} \\ \mathcal{N}_c &\triangleq \bigvee_{10 \leq i \leq 34} \mathcal{N}_{c_i}. \end{aligned}$$

The transitions of the abstract system can be described:  $\forall s, t : \Sigma_a, p : 1 \dots P$ :

$$\begin{aligned} s \llbracket (\mathcal{N}_{a_0})_p \rrbracket t &\triangleq s = t \quad (\text{to allow stuttering}) \\ s \llbracket (\mathcal{N}_{a_1})_p \rrbracket t &\triangleq pc.p = a_1 \wedge pc'.p = a_2 \\ &\wedge S'[x.p] = (S[x.p] \cup me) \\ &\wedge Pres(\mathcal{V} - \{pc.p, S[x.p]\}) \\ s \llbracket (\mathcal{N}_{a_2})_p \rrbracket t &\triangleq pc.p = a_2 \wedge pc'.p = a_1 \\ &\wedge ((me \in S[x.p] \wedge S'[x.p] = \emptyset \wedge \text{Node}'[x.p] = Y \\ &\quad \wedge Pres(\mathcal{V} - \{pc.p, \text{Node}[x.p], S[x.p]\})) \\ &\quad \vee (me \notin S[x.p] \wedge Pres(\mathcal{V} - \{pc.p\}))) \end{aligned}$$

The transitions of the concrete system can be described in the same way. Here we only provide the description of concrete transitions  $c_{16}: \forall s, t : \Sigma_c, p : 1 \dots P$ :

$$\begin{aligned} s[(\mathcal{N}_{c_{16}})_p]t \triangleq & pc.p = c_{16} \\ & \wedge ((m.p = \text{indir}[x.p] \wedge pc'.p = c_{20}) \\ & \vee (m.p \neq \text{indir}[x.p] \wedge pc'.p = c_{18})) \\ & \wedge Pres(\mathcal{V} - \{pc.p\}) \end{aligned}$$

To prove that  $\mathcal{S}_c$  implements  $\mathcal{S}_a$ , we define the state mapping  $\phi: \Sigma_c \rightarrow \Sigma_a$  by showing how each component of  $\Sigma_a$  is generated from components in  $\Sigma_c$ :

$$\begin{aligned} \forall i: 1 \dots N: \text{Node}_a[i] &= \text{Node}_c[\text{indir}_c[i]] \\ \forall i: 1 \dots N: \mathcal{S}_a[i] &= \{p: 1 \dots P \mid pc_c.p \notin \{c_{10}; c_{20}; c_{22}\} \\ & \wedge x_c.p = i \wedge m_c.p = \text{indir}_c[x_c.p]\} \\ \forall p: 1 \dots P: pc_a.p &= (pc_c.p \in [c_{10} \dots c_{18}] ? a_1 : a_2) \end{aligned}$$

where the subscript indicates the concrete or abstract system a variable belongs to, and the remaining variables in  $\Sigma_a$  are identical to the variables occurring in  $\Sigma_c$ .

### A. Invariants

We establish some invariants for the concrete system  $\mathcal{S}_c$ , that will aid us in proving the refinement.

$$\begin{aligned} I1: p \neq q \wedge pc.p \notin [c_{26} \dots c_{32}] \wedge pc.q \notin [c_{26} \dots c_{32}] \\ \Rightarrow mp.p \neq mp.q \\ I2: pc.p \notin [c_{26} \dots c_{32}] \Rightarrow \text{indir}[x] \neq mp.p \\ I3: x \neq y \Rightarrow \text{indir}[x] \neq \text{indir}[y] \end{aligned}$$

In the expression of invariants, free variables  $p$  and  $q$  range over  $1 \dots P$ , and  $x$  and  $y$  range over  $1 \dots N$ . Invariants  $I1$  and  $I2$  indicate that, for any process  $p$ ,  $\text{node}[mp.p]$  can be treated as a “private” node of process  $p$  since only process  $p$  can modify that. Invariant  $I3$  implies that all shared nodes are different. To prove the invariance of  $I1$  to  $I3$ , we postulate

$$\begin{aligned} I4: \forall i: 1 \dots K: \text{prot}[i] &= \#\{x: 1 \dots N \mid \text{indir}[x] = i\} \\ & + \#\{p \mid (pc_p \notin [c_{26} \dots c_{32}] \wedge mp_p = i) \\ & \vee (pc_p = c_{26} \wedge m_p = i)\} \\ & + \#\{p \mid pc_p \in [c_{16} \dots c_{34}] \wedge pc.p \neq c_{32} \wedge m_p = i\} \\ I5: pc.p \in [c_{20} \dots c_{34}] \wedge pc.p \neq c_{32} \wedge mp.q = m.p \\ \Rightarrow pc.q \in [c_{26} \dots c_{32}] \end{aligned}$$

Invariant  $I4$  precisely describe the counter  $\text{prot}[i]$  for each  $i \in 1 \dots K$ . Invariant  $I5$  implies that process  $p$  cannot read the “private” node of other process  $q$ .

Consequently, we have the main reduction theorem for the lock-free implementation using CAS:

**Theorem 2** *The abstract system  $\mathcal{S}_a$  defined in Fig. 1 is implemented by the concrete system  $\mathcal{S}_c$  defined in Fig. 2, that is,  $\exists \phi : \mathcal{S}_c \sqsubseteq \mathcal{S}_a$ .*

For the reason of space, we omit the complete mechanical proof here, and refer the interested reader to [13].

## V. CONCLUSION

The lock-free algorithms often require the use of special atomic processor instructions such as CAS or LL/SC. However, many machine architectures support either CAS or LL/SC with restricted semantics. In this paper, we present a Practical lock-free implementation of the ideal semantics of LL/SC using only pointer-size CAS without causing ABA problem or problems with wrap around. It can be used to provide lock-free functionality for any generic data type. Moreover, to ensure our proof is not flawed, we used the higher-order interactive theorem prover PVS for mechanical support.
