### SUMMARY

Sulfated glycolithocholic acid, a major metabolite of the secondary bile acid lithocholic acid in newborns, is highly cholestatic when administered to experimental animals. Its taurine conjugated analogue, on the other hand, is less hepatotoxic. This thesis deals with the pathophysiology of the potentially toxic lithocholic acid sulfates and the possibilities of dietary intervention to prevent their toxic effects.

It was found that elevated serum levels of sulfated lithocholic acid conjugates in children develop during the course of cholestatic liver disease, due to the well documented shift of bile acids from the enterohepatic to the systemic circulation and/or their increased formation in the liver during cholestasis. However, elevated serum levels may also be the result of an increased influx of these compounds from the intestine, as appeared from reproducible postprandial elevations in serum concentration of the sulfated bile acids after a standardized testmeal in a specific group of patients, which could be prevented by addition of cholestyramine to the testmeal (Appendix paper 1).

Animal studies aimed at the characterization of the enterohepatic circulation of sulfated lithocholic acid conjugates have been performed in unanesthetized and unrestrained rats with normal feeding behaviour, in which the enterohepatic circulation could be interrupted and restored without direct surgical intervention (Appendix paper 2). The use of pentobarbital- anesthesia significantly affected the process of bile formation as well as intestinal bile acid absorption in the rat (Appendix paper 3).

Sulfated lithocholic acid conjugates were efficiently absorbed from the intestine when administered at physiological infusion rates. Absorption was not appreciably inhibited by excess of unsulfated bile acids. However, the presence of excess of calcium in the intestinal lumen selectively reduced their absorption (Appendix paper 4). Sulfated lithocholic acid conjugates were secreted into bile without further hepatic metabolism; urinary secretion was negligible under non-cholestatic conditions. The mechanism of their biliary secretion, studied in rats with an undefined genetic defect in biliary secretion of organic anions, was shown to be different from that of unsulfated bile acids, and probably identical to that of organic anions as bilirubin and dibromosulphthalein (Appendix paper 5).

Low doses of enterally administered sulfated glycolithocholic acid caused a reduction of the biliary secretion of phospholipids and cholesterol, without affecting bile acid secretion and bile flow. This may have been due to interference of the sulfated compound with intracellular lipid transport to the bile canaliculi, or to effects at canalicular level, e.g. by disturbing micellar aggregation. This reduction of biliary lipid secretion may be an initiating event in sulfated glycolithocholic acid-induced cholestasis (Appendix paper 6). Cholestasis was readily induced by intravenous administration of relatively small amounts of sulfated glycolithocholic acid in rats with a depleted endogenous bile acid pool. The presence of endogenous bile acids prevented this cholestatic action, by 1) acceleration of the biliary elimination of the toxic compound, and 2) the maintenance of a high bile flow, which prevented precipitation of the compound in bile canaliculi and/or ductuli (Appendix paper 7). The differences in the hepatotoxic properties between sulfated glyco- and taurolithocholic acids may, at least partly, originate from their differential interactions with calcium; the former rapidly precipitated with calcium in a 1:1 stoichiometry in vitro, whereas the latter did not. Formation of calcium- sulfated glycolithocholic acid complexes may be an important factor in the development of cholestasis in vivo (Appendix paper 8).

Protection of the liver from sulfated lithocholic acid- induced hepatotoxicity can theoretically be exerted at hepatic level by: 1) increasing the availability of taurine for conjugation by dietary means. However, pharmacological doses of taurine are required to alter the pattern of bile acid conjugation significantly in man. 2) maintenance of a high bile flow to accelerate the biliary excretion of the

5

toxic compounds and to prevent their precipitation in the hepatobiliary system. Protection *in vivo* is probably mainly mediated at intestinal level, by withdrawal of the cholestatic sulfated bile acids from the ente-

dibromontiphibaliais (Appendix paper 5) Low doses of enterally administrated aufilal the biliny neutrino of piceynoliphit and cholquard, without affecting bile and scencholquard, without affecting bile and scention and bile flow. This may have been duaintracellular hind transport to the bile causidisting event in suffated compound with using event in suffated approximation of the interference of the aufasted autices at catalitating the paper disting event in suffated glycolithocholic and with a daplated actogenue bile and pice attain stating event in suffated glycolithocholic automs of anisstration of relatively analition of the presence of ordregenue bile and provide the suffated strongenue bile and automs of anisstration of relatively analiand with a daplated andogenue bile and prevented the cholestate action, by 1 acprevented the cholestate action of the action and the compound in bile acousting the action action of the compound in bile acousting the prevented with culture the former mpillip interaction with culture in a 1.1 bilicher formation of valition action in a 1.1 bilicher action action action in a 1.1 bilicher action action

Protection of the liver from suffated lithic thiolic acid minored inputotoxicity can their miterity be exerted at hepatic level by: 1) in creasing the availability of tauring for conjugation by distary means. However, pharmer alogical dozes of mining are required to altri the pattern of bile acid conjugation signifcoully in men. 2) maintenance  $q_2$  a high bili flow to secclerate the biliary exerction of the rohepatic circulation. Binding of sulfated lithocholic acid conjugates to insoluble calcium phosphate in the intestinal lumen (Appendix paper 8) may be of physiological importance in this respect.

of dietary intervention to prevent their toric effects. It was found that elevated serum levels of militied intocholic acid conjugates in onidren develop during the course of obtelestatic liver directs, dan to the well documented the systemic circulation and/or their is capted formation in the liver during choles usis, threever, elevated serum levels may also be the result of an increased india of these compounds from the interstine, as spthese compounds from the interstine, as spthese in serum concentration of the sufficient bile acids after a standardized terminal clevaprevented by addition of cholestyramine to prevented by addition of cholestyramine to
