Behaviour Change to prevent adrenal crises

Abstract

Objective: The incidence of adrenal crisis remains high, particularly for people with primary adrenal insufficiency, despite the introduction of behavioural interventions. The present study aimed to identify and evaluate available evidence of interventions aiming to prevent adrenal crisis in primary adrenal insufficiency.

Design: Systematic review of literature and theoretical mapping.

Methods: MEDLINE, MEDLINE in Process, EMBASE, ERIC, Cochrane CENTRAL, CINAHL, PsycINFO, the Health Management Information Consortium (HMIC) and trial registries were searched from inception to November 2021. Three reviewers independently selected studies and extracted data. Two reviewers appraised the studies for risk of bias.

Results: Seven observational or mixed methods studies were identified where interventions were designed to prevent adrenal crisis in adrenal insufficiency. Patient education was the focus of all interventions and utilised the same two behaviour change techniques, instruction on how to perform a behaviour' and 'pharmacological support'. Barrier and facilitator themes aiding or hindering the intervention included: knowledge, behaviour, emotions, skills, social influences and environmental context and resources. Most studies did not measure effectiveness and assessment of knowledge was variable across studies. Study quality was moderate.

Conclusion: This is an emerging field with limited studies available. Further research is required in relation to the development and assessment of different behaviour change interventions to prevent adrenal crisis.

Behaviour Change to prevent adrenal crises

INTRODUCTION

During acute illness or stress, the adrenal cortex produces higher amounts of the steroid hormone cortisol. Patients with adrenal insufficiency are unable to naturally produce enough cortisol and therefore are required to take daily steroid replacement therapy. These patients are advised to double or triple their dosage or to administer parental hydrocortisone during periods of acute stress, for example, during an illness, after a car accident, or before surgical intervention (1,2). Failure to take and/or adjust their medication can lead to an adrenal crisis, which can be fatal (3).

Adrenal crisis (AC) affects around 1 in 12 patients with Primary Adrenal Insufficiency (PAI) each year (4). Compared to population-matched control groups, patients with PAI attend twice as many outpatient appointments and are almost five times more likely to require hospital admission (5,6). Patients with PAI are hospitalised on average for 4.2 days vs. 0.4 days for matched controls and are more likely to stay in hospital eight to ten days longer (5). Notably, patients who previously experienced an AC are at greater risk of subsequent episodes, and for every 200 incidents of adrenal crisis there will be one death (4,7).

As managing one's medication is behaviour based, interventions designed to change behaviour may assist patients with PAI to adopt the correct regime. Healthcare interventions that increase medication adherence tend to be education based and support the assumption that improving knowledge leads to optimal adherence. To date such interventions have focused on increasing patients' knowledge about their condition, how and when to take medication, and the consequence of not managing their medications well (8,9). However, previous research highlights that while patients do have the required knowledge, they do not apply it when required (10). Behavioural theory can aid the investigation of why this may be the case and can help close the knowledge-behaviour gap.

Behaviour Change to prevent adrenal crises

Deconstructing the interventions, to identify key components of maximum potential, is an essential step towards developing effective and acceptable future interventions (11). Utilising behavioural change models and frameworks such as the Capability, Opportunity and Motivation (COM-B) model and the Theoretical Domains Framework (TDF) provides a systematic approach to critiquing intervention components and techniques already attempted (12,13).

There is a need to reduce the frequency and consequence of AC in people with PAI. While much is known about interventions designed to enhance medication adherence (9,10), there is very little available evidence to inform and help people with PAI manage their medication regimens. Therefore, we undertook a systematic review to identify interventions that had been developed to prevent AC and utilised behavioural theory and frameworks to address the evidence gap.

Prior to commencing the review, we performed a search of the Cochrane database of systematic reviews, Medline (using review filter), and Epistemonikos, which yielded no results for previous systematic reviews in this topic area.

Our systematic review considered the following three research questions:

1. What interventions have been developed and evaluated to prevent AC in adult patients with PAI?
2. What is the effectiveness of the interventions?
3. What are the barriers and facilitators targeted in the interventions?

METHODS

The systematic review was prospectively registered on PROSPERO (CRD 42019137412) and is reported based on the guidelines of the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statement (14) (Supplementary Table 1).

Behaviour Change to prevent adrenal crises

Search strategy

A broad search strategy was designed for MEDLINE (Supplementary Table 2) with no restrictions by publication type, study, or language. The search strategy was adapted for use in different electronic bibliographical databases (15). The search terms included medical subject headings (MeSH) and other keywords (Supplementary Table 2). The following databases were searched from inception to November 2021: MEDLINE, MEDLINE in Process, EMBASE, ERIC, Cochrane CENTRAL for RCTs, CINAHL, PsycINFO and the Health Management Information Consortium (HMIC). Trial registries were also searched including The World Health Organisation and ClinicalTrials.gov. Experts in the field were contacted and citations of screened articles checked to identify any further studies.

Study screening and selection

Titles and abstracts were independently screened by three reviewers (LS, JH, EM) utilising Rayyan software (16). Disagreements were resolved by discussion between the reviewers. The full text of potentially relevant articles was independently screened by two researchers (LS, JH). A third reviewer (AT) was consulted to reach consensus in case of any disagreements. The study selection process was documented with a PRISMA flow diagram.

Study eligibility criteria

Study inclusion criteria are listed in the PICOTTS (Population, Intervention, Comparison, Outcomes, Timing, Setting and Study Design) framework to identify key characteristics (Supplementary Table 3). Papers were excluded if they contained non-empirical data and/or were an expert opinion, editorial, narrative review, or conference abstracts (where the author could not provide further data on request). Only papers published in English were included, as the research team did not have financial resources to translate non-English published papers.

Data extraction

Behaviour Change to prevent adrenal crises

Data was extracted using a piloted data extraction form, adapted from the Cochrane expert group (17) that is suitable for several study designs. Extracted data was independently checked by a second reviewer (JH or KS) and included study design, quality, intervention, and behaviour change characteristics employed and study outcomes (i.e., incidence of adrenal crisis, hospitalisation, mortality, length of stay, and quality of life).

Risk of bias assessment

The AXIS Appraisal Tool (18) was used to appraise bias in all included studies, and the Mixed Methods Appraisal Tool (MMAT) (19) was also used to appraise the van der Meij (2016) study. The risk of bias assessment was undertaken independently by LS and AS, the results compared, and discrepancies discussed until consensus was reached. AXIS and MMAT do not provide or encourage a numerical value for quality (18). Therefore a descriptive summary was provided.

Analysis/synthesis of evidence

To address the research questions, extracted data were arranged in tables and findings were reported narratively. No quantitative synthesis was possible due to the clinical and methodological heterogeneity of the studies, including interventions, outcome measures, study design and conduct.

Through deductive analysis the barriers and facilitators of the intervention were categorised into common study outcome themes. The behavioural analysis consisted of three steps. Firstly, the key components of the interventions were mapped to the 12-point TiDIER checklist (20). Next, the behaviour change techniques (BCTs) utilised in the interventions were identified using the Behaviour Change Technique Taxonomy (BCTT) (version 1) (21). Finally, the BCTs were then mapped to link the BCTT clusters, TDF and COM-B model using the Behaviour Change Wheel components and Cane et al. hierarchy (12,13,21), see Figure 1 for diagrammatical representation.

RESULTS

Behaviour Change to prevent adrenal crises

Seven articles were located. The PRISMA diagram describing the search is described in Figure 2 along with reasons articles were excluded.

Study characteristics

Out of the seven included studies, three were cross sectional studies (22, 23, 24) three undertook cohort studies (4, 25,26), and one utilised mixed methods (27). Questionnaires were predominately used to capture data (4,22,23,24,25). Other methods of data collection included diary (26), medical record review and semi structured interviews (27).

The study aims predominately focused on the evaluation of patients' knowledge (22,27), self-management (24–26) and patients' knowledge and self-management (23,24). The studies (Table 1) were published between 1999 and 2020. All were conducted in European countries. Only one study focused solely on patients with PAI. The remaining studies included patients with AI and reported on these collectively, rather than separating outcome data by PAI and secondary AI. Therefore, the analysis reports collective AI. Four of the studies involved less than 100 participants and three involved more than 100 participants.

Risk of Bias Assessment

The risk of bias utilising the AXIS and MMAT (where appropriate) critical appraisal tools are reported in Supplementary Tables 4 and 5. Due to the observational nature of these studies, confounding variables introduces potential bias that in turn limits confidence in the proposed interventions and their findings. However, two studies attempted to adjust for confounders in relation to knowledge, (24, 27).

Studies recruited between 26 (22) and 423 participants (4), but up to approximately 50% did not respond to invite in one study (4) and the recruitment success rate was not reported in another (22). Across all studies response rate was as follows; not reported (22) 87% (23), 87% (24), 46% (4), 61%

Behaviour Change to prevent adrenal crises

(25), 80% (26) 70% (27) raising the possibility of selection bias. Also, only participants who had insufficient knowledge were invited to participate in the qualitative arm of the mixed methods study (27). Two studies took measures to address non responders (23,25) and the concern of non-response bias by sending a further questionnaire. Outcome variables were measured using validated tools in some studies (4,23,24,25). Whilst less relevant to hard endpoints such as death, for soft endpoints such as quality of life, it was not clear if the researchers were also responsible for delivering the intervention, or if they were blinded as assessors, potentially leading to detection bias. There was no RoB with regards to funding sources or conflicts of interest in any study, although this shows as a bias on the AXIS table. .

Behavioural change interventions developed to prevent AC outcomes

(1) Intervention characteristics

Table 2 describes the intervention characteristics reported applied to the TiDIER checklist (17). The rationale for intervention development in all studies (n=7) was to prevent adrenal crisis (4,22–27). Two studies also ascribed intervention development on the recommendation of Endocrine Society guidelines (24,26,28). No studies included details pertaining to the use of an intervention protocol or reporting guideline, e.g., TiDIER (20).

All interventions (n=7) focused on education (4,22–27). The interventions were delivered in varying formats: one-to-one clinician-to-patient instruction (n=2) (23,27); group education (n=2) (24,25); patient-recorded diaries as part of a structured teaching programme (26); written information only (4); and patient instruction (format unknown) (22).

Minimal information was provided about each intervention; for example, few studies included information about the frequency of intervention, supply of emergency injection kits, and emergency injection training for carers or family members. The place and timing, frequency of intervention, and

Behaviour Change to prevent adrenal crises

personnel involved in delivering the intervention was not always available. Additionally, no study reported the use of theory in the development of the intervention, which is recommended when developing an effective intervention (29), or if the development of the intervention was in collaboration with patients.

(2) Effectiveness of interventions

The reporting of knowledge, frequency of AC, hospitalisation, death, and quality of life was variable across studies (Table 1). Two studies that assessed self-management and knowledge and reported improvement post intervention (4, 27). But the studies did not define knowledge; that is, they did not apply a theoretical underpinning of how 'knowledge' should be measured. Three studies used the same technique to measure knowledge, by asking patients how they would respond to hypothetical situations with objectively right and wrong answers (23,25,27). Assessment of knowledge was categorised as adequate or inadequate, depending on if the participant responded as taking action or not taking action in the hypothetical situations. In one study knowledge was assessed by asking patients to identify which illnesses required dose adjustment (22). Other studies described the percentage of patients who had adjusted their medication or administered an injection during intercurrent illness (4,24,26).

Patients' knowledge of medication and dose adjustment was found to be insufficient to change behaviour when needed to avoid adrenal crises in all but one study (25). Two confounding variables were reported to affect participant level of knowledge; including age (23) and education level (27). With regards to self-reported behaviour, participants that undertook emergency hydrocortisone injection training (including practical training) varied between studies from 60% (22) up to 100% (24). However, during intercurrent illness, participants admitted to not increasing their dose, (4,22,23,26,27).

Behaviour Change to prevent adrenal crises

(3) Barriers and facilitators of targeted interventions

Five studies (22–26) did not explicitly report barriers and facilitators that helped or hindered the application of the intervention. However, themes were identified across studies and could be categorised into five main areas: knowledge, behaviour, emotions, skills, social influences and environmental context and resources (Table 1).

Preparation and administration of the emergency injection was a barrier for some participants and often relied on the support of others to perform the task (27). The number of participants who lived with someone, 63%, was reported only by one study (23). Furthermore, although invited to do so, the number of participants who attended the education with a relative, friend and/or carer was not reported (23,24,27). Participants felt that they could not self-inject for several reasons: no instruction in self-injection (22), lack of confidence/reduction in confidence to inject, preparation of hydrocortisone syringe too difficult (24), no support in carrying out appropriate actions during intercurrent illness and unable to attend (or refused) emergency injection training (27). However, 41% (4) and 91% (24) of participants and/or their relatives were able to administer an emergency injection when indicated and 91% thought they would be able to administer an emergency injection if required (27). Six to nine months following training, 8% of participants felt it unlikely that they could give themselves the injection compared to immediately post training (24).

Having the necessary equipment to perform the emergency injection is also necessary to self-administer. Two studies highlighted that participants did not have appropriate equipment, and, therefore, they would not be able to administer in times of need (4,22). Conversely in three studies, almost all participants were in possession of one or more GC (glucocorticoid) ampoules and/or an emergency kit (24,25,27). In two studies there was a discrepancy between the number in possession of parenteral GC and the number in possession of a needle and syringe (22,27).

Behaviour Change to prevent adrenal crises

Behaviour Change Techniques identified in interventions

The interventions included a narrow range of BCTs (see Tables 4&5). The mean number of BCT's per intervention was six (3-8) (4) (24,25). BCT 'instruction on how to perform a behaviour' and 'pharmacological support' was identified in all interventions and related to information and medication given to the patient to self-manage their condition appropriately (4,22–27). Nine out of 16 BCT clusters were utilised in the studies. BCT clusters 'shaping knowledge,' and 'regulation,' were applied in all studies' (3,21-26). Only one study included 'feedback and monitoring' in their intervention (26), which was delivered through evaluation of self-reported self-management diaries. Interestingly, no interventions included 'goals and planning,' 'association,' 'reward and threat,' 'identify,' 'scheduled consequences,' 'self-belief' or 'covert learning.'

Linking Behaviour Change Techniques to TDF and COM-B

A diagrammatical representation of how the BCTs link to the BCT clusters, TDF and COM-B is provided in Figure 1, and an associated tabular data is provided in Table 4. The particular techniques employed in each study are further described in Table 5. The BCTs identified in the studies are linked to seven TDF domains, 'knowledge,' 'behavioural regulation,' 'skills,' 'beliefs about consequences,' 'emotion,' 'social influences' and 'environmental context and resources' (Table 3). 'Knowledge,' 'beliefs about consequences,' 'emotion,' and 'social influences' were utilised by all studies (n=7). Noticeably, this leaves seven domains (social/professional role and identity, beliefs about capabilities, optimism, reinforcement, intentions, goals, and memory, attention and decision processes) not yet applied in interventions to prevent adrenal crisis and potential areas to be investigated. Four studies included more than two TDF domains (24–27). Despite the absence of several targeted domains all COM-B components 'capability', 'opportunity' and 'motivation' were targeted overall.

DISCUSSION

Behaviour Change to prevent adrenal crises

To our knowledge this is the first systematic review to examine the types of behaviour change interventions already used to prevent AC in adult patients with PAI, their effectiveness, and barriers and facilitators targeted by the intervention. We identified seven studies where interventions were designed to prevent AC in adrenal insufficiency, and the focus of all interventions was patient education. The interventions had been developed with no expressed theoretical underpinning of behaviour change and most studies did not measure effectiveness. Assessment of knowledge was not uniform across studies.

In order to increase the probability of complex interventions being effective and adopted widely, they need to be fostered carefully with all relevant stakeholders (patients, carers, health workers, etc.) and developed using a systematic theoretical basis (29,30). Hence, interventions should be co-designed with those living with primary adrenal insufficiency (31) rather than having little influence (32). While there are a wide range of theoretical models of behaviour change, the inclusion of such models was not expressed in the included studies. Previously successful interventions to address other complex health needs have benefited from their explicit use of behaviour change models, such as diabetes and smoking cessation (33,34). However, overly complex interventions can also lead to a lack of effect or little effect where multiple intervention components fail to address real behavioural needs (35,36). The lack of intervention effectiveness seen in the present systematic review could therefore be related to the absence of use of a theoretical model or an insufficient application of intervention techniques to address untapped barriers to behaviour change. By unpicking the intervention components of the included studies, we have identified areas that can be specifically targeted and techniques that appear to be more favourable in the future.

Whilst all interventions in the identified studies targeted all three COM-B components, the theoretical domains targeted varied. The most frequently targeted domains were 'knowledge', social influence', and 'emotion'. Two studies (22,23) focused on the same BCT clusters and found that patient's self-management was inadequate following these interventions (22,23). However, studies

Behaviour Change to prevent adrenal crises

that adopted comparable BCT clusters in their intervention (n=8) showed improvement of knowledge at follow up (24,25), although knowledge and confidence reported at six to nine months was reduced (24). AC still occurred following education and incidence was reported in two studies (4,26) demonstrating that despite patients' knowledge increasing, this knowledge must not have been applied during times of acute need. This is supported by our teams' findings that having good knowledge does not necessarily translate into behaviour change, as participants still experienced AC (10).

Whilst the purpose of self-management interventions are to provide patients with the skills required to manage their condition (37), our findings indicate that adrenal crises were not avoided. These results are comparable to areas of other chronic diseases, such as heart failure and diabetes where results were also variable and suggested that a multifaceted intervention approach is required (38–40). However, our review found one study that did demonstrate increased patient knowledge and confidence when performing self-injection at baseline, but this was not sustained at six to nine months post intervention (24). This has also been seen in other disease areas, a meta-review of quantitative reviews looking at the effect of supported self-management interventions for people with type II diabetes mellitus demonstrated improvement in HBA1c. However, the effectiveness of the intervention was dependent on the intensity and length of programme as well as ongoing support (41). Therefore, it is important that proposed interventions are deconstructed to identify key components that work, and consideration is given to, frequency, mode, and delivery of intervention.

The current systematic review also adopted a wide perspective of behavioural interventions and the barriers and facilitators targeted by the interventions, specifically around adrenal insufficiency. It has identified intervention techniques already in place, but these may not be working optimally, and other areas that can be targeted to refine the intervention. The current review also highlights current research gaps in this area and the lack of theoretical underpinning related to behavioural

Behaviour Change to prevent adrenal crises

interventions. Future assessments of behavioural interventions to reduce adrenal crisis need to include longer duration of follow up to ascertain that appropriate application of knowledge, regarding dose adjustment, has been applied on multiple occasions. Also, future research should include more granularities of the collective data to develop our understanding of the reasons that can lead to the inappropriate application of knowledge. Better understanding of the effect of education frequency, repeated education along with specific needs of certain populations is needed. Researchers should also consider the utilisation of a theoretical framework when developing an intervention to facilitate development in a systematic way (29,30,42).

Limitations and strengths

This is the first study to systematically synthesise the literature related to interventions that prevent adrenal crisis in patients who have primary adrenal insufficiency. In doing so, this review picks out the barriers and facilitators the interventions were likely to address. The review does not systematically describe the barriers and facilitators the patient experience. Another limitation is the small number of studies identified, not only in the prevention of AC in adult patients with PAI, but all cause AI.

Only seven studies were identified. Additionally, the heterogenous nature of the studies methods and outcomes do not permit us to include a meta-analysis. While the small number of studies located may limit the reliability of our results, it also highlights an opportunity for future studies to explore a largely unexplored topic.

Conclusion

Despite the limitations of the paucity and focus of evidence, the review informs researchers and clinicians of the need to use a comprehensive approach when developing an intervention to aid self-management to prevent adrenal crisis. We found education to be the only type of behavioural change technique interventions utilised, and these interventions did not demonstrate efficacy. For

Behaviour Change to prevent adrenal crises

interventions to be successful in the prevention of adrenal crisis in patients with primary adrenal insufficiency, it is not only important to identify targeted behaviour that require change, but also to incorporate behaviour change theory, throughout both the development and implementation of interventions.

SAI		225	N/A	201 ¹	175	45	68
TAI						1	
Iatrogenic		7					
Unknown		4					
Intervention	Hydrocortisone & emergency injection education	Standardised group education information on adrenal physiology and AI GC dose adjustment during physical, or psychological stress, and AC. Emergency management and practical training of sc/im hydrocortisone injection. Equipped with an emergency card and injection set, written instructions on AI, dose adjustment and IM self-injection. Exchange of personal experiences of AI.	Standard procedure education	Written instructions	Education group meeting	Patient recorded diaries as part of nationwide structured teaching programme	Education programme
Participants receiving intervention, <i>n</i>	25	526	84	423	246	80	83

Participants receiving comparator, <i>n</i>	Nil	Nil	Nil	Nil	44	Nil	Nil
Research Objective	Determine patients with PAI knowledge of GC dose adjustment, injection supply and self-administration	Evaluate the knowledge and feelings of patients with AI in the management of adrenal emergencies following education in a standardised patient education programme.	Assess patients with PAI/SAI on HC replacement, level of information and ability to take appropriate action in cases of inter-current illness	Assess incidence, precipitating causes, potential risk factors and mortality associated with AC in patients with PAI/SAI in educated patients	Assess the self-management in patients with PAI/SAI pre and six months post glucocorticoid education group compared to participants who have never experienced training	Evaluate self-management of patients with PAI/SAI/TAI to enhance existing education programme	Assess educated patients with PAI/SAI knowledge of GC stress instructions and explore underlying causes and care needs in patients with insufficient knowledge
Theme focus	Patient Knowledge	Patient knowledge & self-management	Patient knowledge & self-management	Self-management	Self-management	Self-management	Patient knowledge
Design/Method	Cross sectional (one time) questionnaire-based audit	Prospective, longitudinal, multi centre questionnaire-based study.	Cross sectional (one time) questionnaire-based survey	Prospective observational, multicentre, longitudinal questionnaire (across 2 years with questionnaire every 6 months) based study.	Longitudinal questionnaire- based study; consisting of pre and post intervention survey	Prospective, multicentre, observational diary-based study	Mixed methods study Quantitative methods- Statistical tests using hospital records and coded interview responses (correct/ incorrect) Qualitative methods- Content analysis of thematically coded intervention responses.
Setting	One UK endocrine unit	Four University Hospital endocrine units, two endocrinology medical practices and two medical practices	One University Hospital endocrine out-patient clinic	Four University Hospitals	One University Hospital endocrine unit	Four tertiary endocrine centres	One University Hospital endocrine unit

Hospitalisation	n/a	n/a	6% (5/84) were admitted to hospital for (AC) febrile events	14% (~59/423)	n/a	2.5% (2/80)	n/a
Deaths	n/a	n/a	n/a	~1% (4/423)	n/a	0% (0/80)	n/a
Quality of life	n/a	Prior to education 59% of patients felt they were doing 'very well'/'well', regarding their AI. 33% were satisfied, and 7.9% felt they were doing 'bad or very bad'. 66% of patients felt that their personal life was affected due to AI. 54% of employed patients felt AI had affected them.	n/a	n/a	n/a	n/a	n/a

Study Outcomes applied to TDF domains

Knowledge	28% (7/25) correct action, 12% totally incorrect action (3/25).	significantly increased after education (all $P < 0.001$). Recognition of signs and symptoms of incipient AC (2.2 ± 0.7 v 2.5 ± 0.9 , $P < 0.001$) and perception of self-management was significantly better immediately after education than 6-9 months post education (2.2 ± 0.8 v 2.6 ± 0.9 , $P < 0.001$).	~54% (45/84) answered at least 4/6 hypothetical questions about acute stress correctly and either with at least one correct answer to question 7 or 8. 5% (4/84) answered all questions correctly. There was a marked difference with knowledge and age. 59% (50/84) considered themselves well informed.		Comparison between baseline and follow up in the intervention group, saw an increase in the number of hypothetical questions answered correctly. Before intervention there were no significant differences between control responses to hypothetical questions about their condition. However, significantly more in the group that were to receive intervention v responders mentioned taking action in case of flu and raised temp ≥ 38 c. After the intervention, the treatment group were more likely to report that they would take appropriate action after vomiting, and after repeated vomiting/diarrhoea and a concerning temperature.	51.8% (43/83) were unable to answer the hypothetical questions correctly. Level of education was significantly associated with knowledge.	
Behaviour	60% (15/25) had never changed their GC dose despite 80% (12/15) having the disease >16 years. 8% (2/25) could self-administer (1 did not take kit on holiday). 80% (20/22) carried steroid card/wore medical alert jewellery.		~38% (14/37) of patients who had reported at least one episode of pyrexia during past year had not increased their GC dose. ~80% (67/84) possessed a steroid card	53% (n/a) of patients who reported deterioration in health did not seek medical advice. 18% (n/a) reported no GC dose adjustment. From 78 episodes of vomiting, 12% (n/a) did not adjust their steroids, 18% (n/a) used a GC suppository 30% (n/a) adjusted their oral GC dose and 41 % responded appropriately and gave parenteral GC (Total = 101% due to rounding). Patients who experienced AC during follow up were more likely to adjust GC dose during fever (89% v 63%) and other events requiring adjustment (78% v 62%).		~89% (71/80) of patients experienced at least one day of discomfort, which required dose adjustment on 35% of discomfort days. Discomfort documented in 13.6% of all recorded days. GC dose adjustment during symptoms which might indicate GI infection only 30% doubled the dose. Several patients (number unspecified) doubled or tripled their dose even though symptom score was low	4.8% never increased their dose.
Beliefs about capabilities		Significantly fewer patients would dare to perform emergency injection at 6-9 months compared to immediately after education. Younger patients (<55 years) were more confident to self-inject compared to older patients (74, 89% v 62, 77%) at baseline and long term follow up. More males were confident than females to self-inject at baseline and immediately after education (75, 95 % v 64, 86%).					91.2% (62/83) of those taught, thought themselves capable to administer emergency injection.
Emotions		Significantly more patients stated that they would dare to perform an injection after education compared to baseline (68% v 91% v 83% $P < 0.001$). 94% Patients felt that a standardised patient education programme would improve their quality of life, this increased to 98% after education and 95% 6-9 months post education			The control group were more satisfied with the information they had received in the past than the treatment group		
Skills	40% (10/25) said never had been instructed on HC injection, of whom none had supply of parental HC.						81.9% (68/83) and/or social network knew how to administer HC injection. 18% (15/83) had never received training
Social influences	Social influences & environmental context and resources - 60% (15/25) recalled instruction of parental HC, 40% (6/15) had a supply (1 had no needles/syringes, 1 expired vial) 2 thought they would not be able to self-administer						
Environmental context and resources			~80% (67/84) possessed a steroid card.	96% (~406/423) were equipped with emergency card and 30 % (~127/423) had an emergency HC kit. Patients who had experienced AC during follow-up were more likely to be in possession of emergency kit at baseline (52% v 26%).	After the intervention, the treatment group had more self-management tools; GC instruction leaflet, medicine passport/medical alert jewellery		97.6% (78/83) had a 100mg vial of parental HC, however only 86.7% (72/83) had needles and syringes. 43.3% wore medic alert identification all the time.

n/a – not available; PAI – primary adrenal insufficiency; AAD- autoimmune Addison's disease; Pt/yr – patient years; AC- adrenal crisis; SAI – secondary adrenal insufficiency; AE – adrenal emergency; TAI – tertiary adrenal insufficiency; HC- hydrocortisone; TDF- theoretical domains framework; GC- glucocorticoid

¹ number of SAI patients reported in tables 1 & 2 (n=201), table 3 & abstract (n=202)

Intervention	Hydrocortisone & emergency injection education	Standardised group education	Standard procedure education	Written instructions	Educational group meeting	National structured teaching programme	Standardised individual education
	Parental hydrocortisone available						
Why	To adequately prepare people with adrenal insufficiency to manage their GRT during intercurrent illness	To standardise and adequately prepare people with adrenal insufficiency to manage their GRT during intercurrent illness	To adequately prepare people with adrenal insufficiency to manage their GRT during intercurrent illness	Standardise information for patients with adrenal insufficiency to manage their GRT during intercurrent illness/acute need	To adequately prepare people with adrenal insufficiency and their family/friends to manage their GRT during intercurrent illness/acute need	Identify areas of patients' self-management during times of intercurrent illness/acute need that may require additional support	To adequately prepare people with adrenal insufficiency and their family/friends to manage their GRT during intercurrent illness/acute need
What							
Materials	Equipped with an emergency injection set	Equipped with an emergency card and injection set. Written instructions on AI, dose adjustment and IM self-injection.	Equipped with a steroid card.	Equipped with written instructions on GC adaptation.	On call endocrinologist available to contact 24 hrs/7days a week.	n/a	The educational material is presented as slides, and the patient is equipped with written information to take with them after the session.
Procedures	Provided instructions on GC dose adjustment	Provided information about adrenal physiology and AI, AC, dose adjustment of the daily oral GC dose during physical or psychological stress, emergency management and self-injection of HC. Practical training for patients and relatives in preparation and administration of IM or SC emergency hydrocortisone injection. Peer support	Provided instruction and information on HC treatment and dose adjustments.	Provided instructions on GC administration and to immediately contact emergency HCP for parental HC in case of diarrhoea & vomiting.	Provided information about AI, treatment, stress related GC dose adaptation, parental administration guidance (with practical training), and how/when to contact hospital. Peer support.	A national structured teaching programme provided information about AI, dose adaptation, and emergency situations. In addition, to evaluate this intervention, 100 patients were asked to complete daily diary entries about their condition. For this purpose of this project, the diary is considered part of the intervention	Provided information about AI and daily medicating, training in adjusting the dose during stress, and training in injection techniques. The importance of the emergency card/jewellery was discussed and provided. Travel advice was given.
Who provided	Clinical unit representatives	Endocrine nurse and endocrinologist	Trained endocrinologists	Hospital researchers as part of their study.	Nursing staff	n/a	Nurse practitioner

Abstract	2	See the PRISMA 2020 for Abstracts checklist.	Page 2
INTRODUCTION			
Rationale	3	Describe the rationale for the review in the context of existing knowledge.	Page 3
Objectives	4	Provide an explicit statement of the objective(s) or question(s) the review addresses.	Page 4
METHODS			
Eligibility criteria	5	Specify the inclusion and exclusion criteria for the review and how studies were grouped for the syntheses.	Page 5 & Supplementary file Table 3
Information sources	6	Specify all databases, registers, websites, organisations, reference lists and other sources searched or consulted to identify studies. Specify the date when each source was last searched or consulted.	Page 5
Search strategy	7	Present the full search strategies for all databases, registers and websites, including any filters and limits used.	Supplementary file Table 2
Selection process	8	Specify the methods used to decide whether a study met the inclusion criteria of the review, including how many reviewers screened each record and each report retrieved, whether they worked independently, and if applicable, details of automation tools used in the process.	Page 5
Data collection process	9	Specify the methods used to collect data from reports, including how many reviewers collected data from each report, whether they worked independently, any processes for obtaining or confirming data from study investigators, and if applicable, details of automation tools used in the process.	Page 6
Data items	10a	List and define all outcomes for which data were sought. Specify whether all results that were compatible with each outcome domain in each study were sought (e.g. for all measures, time points, analyses), and if not, the methods used to decide which results to collect.	Page 6
	10b	List and define all other variables for which data were sought (e.g. participant and intervention characteristics, funding sources). Describe any assumptions made about any missing or unclear information.	Page 6
Study risk of bias assessment	11	Specify the methods used to assess risk of bias in the included studies, including details of the tool(s) used, how many reviewers assessed each study and whether they worked independently, and if applicable, details of automation tools used in the process.	Page 6
Effect measures	12	Specify for each outcome the effect measure(s) (e.g. risk ratio, mean difference) used in the synthesis or presentation of results.	NA
Synthesis methods	13a	Describe the processes used to decide which studies were eligible for each synthesis (e.g. tabulating the study intervention characteristics and comparing against the planned groups for each synthesis (item #5)).	Page 6-7

Section and Topic	Item #	Checklist item	Location where item is reported
	13b	Describe any methods required to prepare the data for presentation or synthesis, such as handling of missing summary statistics, or data conversions.	NA
	13c	Describe any methods used to tabulate or visually display results of individual studies and syntheses.	Page 6-7
	13d	Describe any methods used to synthesize results and provide a rationale for the choice(s). If meta-analysis was performed, describe the model(s), method(s) to identify the presence and extent of statistical heterogeneity, and software package(s) used.	Page 6-7
	13e	Describe any methods used to explore possible causes of heterogeneity among study results (e.g. subgroup analysis, meta-regression).	NA
	13f	Describe any sensitivity analyses conducted to assess robustness of the synthesized results.	NA
Reporting bias assessment	14	Describe any methods used to assess risk of bias due to missing results in a synthesis (arising from reporting biases).	NA
Certainty assessment	15	Describe any methods used to assess certainty (or confidence) in the body of evidence for an outcome.	NA
RESULTS			
Study selection	16a	Describe the results of the search and selection process, from the number of records identified in the search to the number of studies included in the review, ideally using a flow diagram.	Figure 2 – Page 42
	16b	Cite studies that might appear to meet the inclusion criteria, but which were excluded, and explain why they were excluded.	Figure 2 – Page 42
Study characteristics	17	Cite each included study and present its characteristics.	Table 1 & – Pages 28-35
Risk of bias in studies	18	Present assessments of risk of bias for each included study.	Supplementary files 4 & 5
Results of individual studies	19	For all outcomes, present, for each study: (a) summary statistics for each group (where appropriate) and (b) an effect estimate and its precision (e.g. confidence/credible interval), ideally using structured tables or plots.	Pages 28-40 Tables - 1,2,3,4,5
Results of syntheses	20a	For each synthesis, briefly summarise the characteristics and risk of bias among contributing studies.	Page 8 Supplementary files 4 & 5
	20b	Present results of all statistical syntheses conducted. If meta-analysis was done, present for each the summary estimate and its precision (e.g. confidence/credible interval) and measures of statistical heterogeneity. If comparing groups, describe the direction of the effect.	NA
	20c	Present results of all investigations of possible causes of heterogeneity among study results.	Page 7-8
	20d	Present results of all sensitivity analyses conducted to assess the robustness of the synthesized results.	NA
Reporting biases	21	Present assessments of risk of bias due to missing results (arising from reporting biases) for each synthesis assessed.	Supplementary

Section and Topic	Item #	Checklist item	Location where item is reported
			files 4 & 5 & Page 8
Certainty of evidence	22	Present assessments of certainty (or confidence) in the body of evidence for each outcome assessed.	NA
DISCUSSION			
Discussion	23a	Provide a general interpretation of the results in the context of other evidence.	Page 13-15
	23b	Discuss any limitations of the evidence included in the review.	Page 15-16
	23c	Discuss any limitations of the review processes used.	NA
	23d	Discuss implications of the results for practice, policy, and future research.	14-16
OTHER INFORMATION			
Registration and protocol	24a	Provide registration information for the review, including register name and registration number, or state that the review was not registered.	Page 2
	24b	Indicate where the review protocol can be accessed, or state that a protocol was not prepared.	Page 2
	24c	Describe and explain any amendments to information provided at registration or in the protocol.	Page 2
Support	25	Describe sources of financial or non-financial support for the review, and the role of the funders or sponsors in the review.	Page 17
Competing interests	26	Declare any competing interests of review authors.	Page 17
Availability of data, code and other materials	27	Report which of the following are publicly available and where they can be found: template data collection forms; data extracted from included studies; data used for all analyses; analytic code; any other materials used in the review.	Page 17

Supplementary File Table 3 - Table 3 PICOTSS inclusion criteria

PICOTSS*	Inclusion criteria
Patient population	Adults aged 18 years or older Patients with PAI** On GRT*
Intervention	All behavioural change interventions
Comparison group(s)	Usual care or any other intervention
Outcomes (Effectiveness)	Incidence of AC*** and/or hospitalisation Length of hospitalisation Mortality
Outcomes (Qualitative)	Quality of life Identification of behaviour barriers and facilitators in the prevention of AC
Timing	Any time point
Setting	Any setting
Study design	Human Systematic reviews All quantitative Any type of mixed methods or qualitative-only research that explores the barriers and/or facilitators and/or interventions to prevent AC

*PICOTS - Population, Intervention, Comparison, Outcomes, Timing, Setting.

**PAI – Primary Adrenal Insufficiency

**GRT – Glucocorticoid replacement therapy

***AC – Adrenal Crisis

Supplementary File Table 4 –AXIS appraisal

Study	Clear aims & objectives?	Study design appropriate for aims?	Sample size justified?	Target population clearly defined?	Sample frame representative of target population?	Selection process representative of target population?	Measures taken to address non responders?	Risk factor and outcome variables measured appropriate?	Risk factor and outcome variables measured correctly using validated instruments?	Is it clear what was used to determine statistical significance and/or precision estimates?	Were the basic data adequately described?	Does the response rate raise concerns about non response bias?	Was there information about non responders described?	Were the results internally consistent?	Were the results presented for all the analyses described in the methods?	Discussions and conclusions justified by results?	Limitations of the study discussed?	Funding sources or conflicts of interest that may affect interpretation of results?	Ethical approval or consent of participants attained?

Supplementary File Table 5 –MMAT (2018) critical appraisal

Study	Clear research questions?	Do the collected data allow to address the research questions?	Is the qualitative approach appropriate to answer the research question?	Qualitative data collection methods adequate to address the research question?	Findings adequately derived from the data?	Interpretation of results sufficiently substantiated by data?	Coherence between qualitative data sources, collection, analysis and interpretation?	Is randomization appropriately performed?	Groups comparable at baseline?	Are there complete outcome data?	Are outcome assessors blinded to the intervention provided?	Did the participants adhere to the assigned intervention?	Participants representative of the target population?	Measurements appropriate regarding both the outcome and intervention (or exposure)?	Are there complete outcome data?	Confounders accounted for in the design and analysis?	During the study period, is the intervention administered (or exposure occurred) as intended?	Sampling strategy relevant to address the research question?	Sample representative of the target population?	Are the measurements appropriate?	Is the risk of nonresponse bias low?	Statistical analysis appropriate to answer the research question?	Adequate rationale for using a mixed methods design to address the research question?	Are the different components of the study effectively integrated to answer the research question?	Are the outputs of the integration of qualitative and quantitative components adequately substantiated?	Are divergences and inconsistencies between quantitative and qualitative results adequately substantiated?	Different components of study adhere to the quality criteria of each tradition of methods involved?
