41

42 **ABSTRACT (249 words)**

43 **Context:** Extracellular matrix (ECM) in subcutaneous adipose tissue (scAT) undergoes pathological remodeling
44 during obesity. However, its evolution during weight loss remains poorly explored.

45 **Objective:** To study histological, transcriptomic and physical characteristics of scAT ECM remodeling during the
46 first year of bariatric surgery (BS)-induced weight loss and their relationships with metabolic and bioclinical
47 improvements.

48 **Patients and Main measures:** 118 morbidly obese candidates for BS were recruited and followed during one-year
49 post-BS. ScAT surgical biopsy and needle aspiration, as well as scAT stiffness measurement were performed in
50 three sub-groups before and post-BS. 14 non-obese non-diabetic subjects served as controls.

51 **Results:** Significantly increased picrosirius-red stained collagen accumulation in scAT post-BS was observed along
52 with fat mass loss, despite metabolic and inflammatory improvements and undetectable changes of scAT stiffness.
53 Collagen accumulation positively associated with M2-macrophages (CD163⁺ cells) before BS but negatively after.
54 Expression levels of genes encoding ECM components (e.g. COL3A1, COL6A1, COL6A2, ELN), cross-linking
55 enzymes (e.g. LOX, LOXL4, TGM), metalloproteinases and their inhibitors were modified one-year post-BS. LOX
56 expression and protein were significantly decreased, and associated with decreased fat mass, as well as other cross-
57 linking enzymes. Although total collagen I and VI staining decreased one-year post-BS, we found increased
58 degraded collagen I and III in scAT, suggesting increased degradation.

59 **Conclusions:** After BS-induced weight loss and related metabolic improvements, scAT displays major collagen
60 remodeling with an increased picrosirius-red staining that relates to increased collagen degradation and importantly
61 decreased cross-linking. These features are in agreement with adequate ECM adaptation during fat mass loss.

62

63 The extracellular matrix (ECM) in subcutaneous adipose tissue (scAT) undergoes substantial pathological
64 remodeling during obesity. ECM accumulation, usually called fibrosis, is defined as an excessive deposition of
65 ECM components (mainly cross-linked collagens) and impaired degradation (1). ECM accumulation is important in
66 the regenerative step where it replaces damaged cells. However, if the damage persists, excessive ECM deposition
67 harms tissue homeostasis and function (2). In obesity, scAT ECM accumulation reduces tissue plasticity and results
68 in adipocyte dysfunction, ectopic fat storage, and metabolic disorders (1). Studies have shown the detrimental
69 consequences of ECM accumulation in obesity and their associations with comorbidities. In mice, genetic ablation
70 of MT1-MMP, a membrane anchored metalloproteinase degrading collagen I, leads to increased peri-adipocyte
71 fibrosis and severe metabolic complications such as hepatic steatosis (3). Likewise, Collagen VI accumulation in
72 obesity is associated with insulin resistance (4,5). By contrast, the absence of collagen VI in high-fat diet or *ob/ob*
73 mice results in uninhibited adipocyte expansion and associates with metabolic and inflammatory improvements (6).
74 In obese subjects, scAT fibrosis is increased (7,8). Moreover, higher scAT fibrosis at baseline is associated with
75 lower weight loss one year post-bariatric surgery (BS) (7,9). In addition, scAT pericellular fibrosis is associated
76 with liver fibrosis, suggesting that obesity is a profibrotic condition (9). Finally, the pericardial fat secretome was
77 also found to promote myocardial fibrosis (10). Overall, these studies underline the potential deleterious effects of
78 obesity-induced scAT ECM accumulation.

79 Mechanistically, scAT fibrosis leads to adipocyte dysfunction and fibro-inflammation through a mechano-
80 transduction pathway (11). Lysyl oxidase (LOX), an important matrix fibers' cross-linking enzyme, contributes to
81 tissue mechanical properties (12). In AT, LOX expression is up-regulated in high-fat diet or *ob/ob* mice. By
82 contrast, inhibition of LOX activity leads to improved metabolism and inflammation (13). In obese subjects, scAT
83 LOX expression is also increased (11). ScAT stiffness, measured non-invasively by transient elastography,
84 associates with picrosirius-red stained scAT fibrosis and altered glucose homeostasis (9).

85 ECM turnover, a crucial process during excess ECM accumulation, is predominately regulated by the
86 balance between matrix metalloproteinases (MMPs) and their endogenous tissue inhibitor of metalloproteinases
87 (TIMPs). In obesity, a new relationship between MMPs and TIMPs is established and enables tissue remodeling.
88 Enzymes (e.g. MMP-3, -9, -11, -12, -13, -16, and -24) are expressed at low level in scAT, but are rapidly up-
89 regulated during obesity, which eventually favors scAT expansion (1). Weight loss represents another condition
90 that induces scAT remodeling, exhibiting by changes in expression of many ECM genes soon after BS (8,14).

91 Some studies have shown increased ECM deposition, e.g. up-regulated collagens, particularly COL6A3, after
92 major weight loss in a long-term (14,15). However, most of these studies focused on selected collagens at
93 expression levels and did not explore the overall ECM characteristics. Furthermore, no study has yet evaluated the
94 links between scAT ECM remodeling, stiffness, and modifications in cross-linking enzymes, and improved
95 metabolic parameters after weight loss.

96 Herein, we examined fibrillar collagen accumulation, synthesis, and degradation as well as cross-linking
97 enzymes, macrophage infiltration and scAT stiffness during the first year post-BS. We also analyzed relationships
98 between ECM properties and metabolic and inflammatory parameters improvements observed post-BS.

99

100 **Materials and Methods**

101 **Study Population**

102 **A total of 118** morbidly obese candidates for BS who met the recruitment criteria as described (7) were enrolled at
103 the Institute of Cardiometabolism and Nutrition (ICAN), Nutrition Department and operated in the Department of
104 Surgery, Pitié-Salpêtrière Hospital (Paris). **Due to the difficulties to obtain large amount of scAT surgical**
105 **biopsy sample in every subject during the follow-up and the number of experiments to perform on these**
106 **samples, we divided our overall cohort into 3 groups according to the different scAT measurements that**
107 **were realized** (study flowchart see Figure 1). However, subjects were part of the same prospective cohort and
108 baseline (T0) characteristics were not significantly different (Table 1).

109 Group1 subjects (**n=52, age 40.1±10.2yr, female n=37 (71%), BS procedures: gastric banding (GB) n=8 (15%),**
110 **sleeve gastrectomy (SG) n=16 (31%), Roux-en-Y gastric bypass (RYGB) n=28 (54%)**) accepted surgical scAT
111 biopsy before (T0) and 3 months (T3) and 12 months (T12) post-BS. Surgical biopsy was performed under local
112 anesthesia in peri-umbilical area as described (15,16). The collected scAT samples were used for explant
113 experiments and histological analysis.

114 Group2 (**n=35, age 38.0±10.0yr, female n=24 (69%), BS procedures: GB n=3 (8%), SG n=16 (46%), RYGB**
115 **n=16 (46%)**) underwent at T0, T3, and T12 scAT stiffness measurement (see below). A sub-group of 14 non-
116 diabetic women from Group2 underwent scAT needle aspiration for RT-PCR analysis. Notably, 11 individuals with
117 stiffness measurement were also part of Group1.

118 Group3 (n=42, age 42.9±10.5yr, female n=42 (100%), BS procedures: RYGB n=42 (100%)) underwent scAT
119 needle aspiration at T0 and T12 for microarray analysis.

120 14 non-obese non-diabetic subjects (age=41.6±14.1yr, female 29%, BMI=23.2±3.3 kg/m²), who had elective
121 abdominal programmed surgery without inflammatory diseases as described (7), were recruited as a control group.
122 Perioperative scAT biopsy samples were collected in the same location as in obese subjects. Ethical approval was
123 obtained from the Research Ethics Committee of Pitié-Salpêtrière Hospital (CPP Ile de France). Informed written
124 consent was obtained from all subjects.

125 **Clinical, Anthropological and Biological Parameters**

126 Body composition was evaluated by whole body fan-beam dual energy X-ray absorptiometry (DXA) scan (Hologic
127 Discovery W, Bedford, MA) as described (9). Blood samples were collected after 12-hour overnight fast at T0, T3,
128 and T12. Clinical variables were measured as described (7). Pancreatic beta-cell function (insulin secretion), insulin
129 sensitivity and resistance were estimated using Homeostatic Model Assessment – Continuous Infusion Glucose
130 Model Assessment (HOMA-CIGMA) (17) .

131 **Measurement of scAT Shear Wave Speed by Transient Elastography**

132 A new non-invasive medical device based on transient elastography (18), AdiposcanTM (Echosens, Paris, France),
133 was developed to measure scAT shear wave speed (SWS) associated with scAT stiffness (9,19). ScAT stiffness
134 was measured by the same operator in obese subjects (Group2) in the right peri-umbilical region at T0, T3 and T12.

135 **Transcriptomic Experiments**

136 ScAT samples obtained by needle aspiration at T0 and T12 (Group3) were stored at -80°C for microarray analysis.
137 Total RNA extraction, amplification, hybridization and raw data analysis were performed as described (20). The
138 complete dataset is published in the NCBI Omnibus (<http://www.ncbi.nlm.nih.gov/geo/>) through the series
139 accession number GSE72158.

140 RT-PCR for selected genes was performed as described (20), using total RNA extracted from scAT needle
141 aspiration in 14 non-diabetic obese women (Group2) at T0, T3 and T12.

142 **Tissue Preparation and Histological Analysis of scAT**

143 A piece of surgical biopsy sample was fixed and embedded in paraffin and sliced into 5µm-thick sections. Collagen
144 was stained with picosirius-red (mainly collagen I and III) and analyzed using Calopix software (Tribvn, Châtillon,
145 France) in 36 subjects (Group1) at T0, T3 and T12 as described (9). Total collagen accumulation represents the

146 ratio of the stained fibrous area to the total tissue surface. Pericellular collagen accumulation (i.e. collagen
147 surrounding adipocytes) represents the ratio of the stained area in 10 random fields avoiding fibrosis bundles.
148 Adipocyte diameters were evaluated in the same 10 fields. Pericellular collagen accumulation was adjusted by
149 adipocyte size to eliminate the effects of different adipocyte sizes in measure fields. Collagen I and VI, degraded
150 collagen I, LOX and macrophages were detected by immunohistochemistry (**IHC**) using specific antibodies
151 (Supplemental Table 1). Total macrophages were defined as CD68⁺ cells and M2-macrophages as CD163⁺ cells.
152 Their results are expressed as the number of CD68⁺ or CD163⁺ cells related to 100 adipocytes (21). Collagen and
153 elastin structures were analyzed using confocal microscopy and second-harmonic generation (SHG) microscopy on
154 another piece of fixed scAT sample in 3 random obese subjects (Group1) as described (11).

155 **ScAT Explant *in vitro***

156 Piece of surgical biopsy samples (Group1) was placed in a culture medium enriched in endothelial cell basal
157 medium (Promocell, Heidelberg, Germany), supplemented with 1% albumin free fatty acids (PAA Laboratoires,
158 Velizy-Villacoublay, France) and antibiotics. After 24-hour incubation at 37°C, scAT explant secretion media were
159 collected and frozen at -80°C for ELISA and zymography. The explant secretion was normalized to AT weight
160 according to the ratio of 1mL of culture medium for 0.1g scAT.

161 **Protein Determination in scAT Explant**

162 The concentrations of collagen III formation marker, N-proteases cleaved N-terminal propeptides of collagen III
163 (PRO-C3), and degradation marker, MMP-9-generated neoepitope fragments of collagen III (C3M), in scAT
164 explants were evaluated using two competitive ELISA kits developed by Nordic Bioscience A/S (Herlev, Denmark)
165 (22). The protein profiles of proMMP-2 and proMMP-9 were analyzed by zymography as described (23).

166 **Statistical Analyses**

167 Data are expressed as mean \pm SD, categorical variables as numbers and percentages, and values in graphs as mean
168 \pm SEM. Categorical data were analyzed using Fisher's exact test. For continuous data, repeated one-way ANOVA
169 was used to compare more than two groups and Holm-Sidak's parametric multiple comparison for post-hoc
170 analysis; student's t-test was used to compare two groups. **K-means for longitudinal data (K_mL) was used to**
171 **cluster scAT stiffness trajectories.** For small sample size (i.e. n<30), data were first transformed by natural
172 logarithm if they did not follow a Gaussian distribution. Two-tailed p-values were considered significant below

173 0.05. All analyses were conducted using R software version 3.0.3 (<http://www.r-project.org>) and GraphPad Prism

174 6.0.

Results

Increased Collagen Deposition in scAT during BS-induced Weight Loss

Using picrosirius-red staining, scAT collagen was quantified in **36-paired** obese subjects (Group1) at **baseline (T0) and during the follow-up (T3 and T12)**. No significant difference in **collagen accumulation** was found among the different BS procedures at baseline (Supplemental Table2). More abundant and thicker bundles of collagen fibers traversing the scAT were observed at T3 and T12 (Figure 2A, B, C). Several parenchymal areas were filled with less well-organized collagen in post-operative tissues (Figure 2C, enlarged image). A significant increase in the average of total and pericellular collagen was observed at T3 and T12 (Figure 2D). As expected, adipocyte size significantly decreased post-BS (Figure 2E), but this reduction was not correlated with collagen accumulation. Moreover, the increase in pericellular collagen remained significant after adjustment for adipocyte size reduction. Importantly, the fat mass reduction was negatively correlated with pericellular collagen accumulation ($r=-0.40$, $p<0.05$). No other associations were observed between collagen accumulation and metabolic or inflammatory variables except for systemic HDL-cholesterol (Supplemental Table3). Importantly, the results hold true in subgroup analysis in each different bariatric surgery technic data not shown).

Undetectable Changes in Tissue Stiffness despite Increased scAT Collagen Accumulation in scAT

Since we **previously** showed that collagen accumulation was associated with scAT rigidity **and metabolic alterations** in obesity (9), we **next** aimed to investigate scAT stiffness changes post-BS using Adiposcan™ at T0, T3 and T12 (Group2). **To our surprise**, despite increased collagen accumulation, no significant change in **average** SWS was detected at T3 and T12 compared to T0 (T0: $0.90\pm 0.29\text{m/s}$, T3: $0.88\pm 0.28\text{m/s}$, T12: $0.93\pm 0.43\text{m/s}$, $p=0.58$, Figure 2F). **Using K-means for longitudinal data (KmL) to cluster scAT stiffness individual trajectories**, we observed **2 major clusters (A and B) of stiffness changes that suggest different profiles of tissue response post-BS (Figure 2G)**. **Cluster A (n=24) had significant lower stiffness than Cluster B (n=12) at T0 (Cluster A $0.78\pm 0.15\text{m/s}$ vs Cluster B $1.17\pm 0.35\text{m/s}$, Wilcoxon test $p<0.05$) and T12 (Cluster A $0.68\pm 0.18\text{m/s}$ vs Cluster B $1.47\pm 0.32\text{m/s}$, Wilcoxon test $p<0.05$), while Cluster B displayed a V-shape profile with an initial decrease and a subsequent increase. However, we did not observe significant bioclinical differences at any time points that could possibly explain these trajectories (Supplemental Table 4). The absence of significant change in average scAT SWS suggested that stiffness was not increased after surgery**

203 **despite increased picrosirius-red stained collagen. Therefore, this increase in collagen accumulation could be**
204 **considered as adaptive ECM remodeling requiring further investigation.**

206 **M2-Macrophages Associate with Collagen Accumulation in scAT**

207 M2 cells, alternatively activated macrophages, are implicated in the resolution phase of inflammation and tissue
208 remodeling (24). **Using IHC**, M2 cells (i.e.CD163⁺ cells) and total macrophages (i.e.CD68⁺ cells) in scAT were
209 quantified in 15 obese subjects from Group1 at T0 and T12. The CD163⁺/CD68⁺ ratio increased between T0 and
210 T12 (0.38±0.20 vs. 0.78±0.58, p<0.01, Figure 3A), in agreement with a switch toward M2-macrophages during
211 weight loss and their role in tissue remodeling. At T0, a strong positive association between CD163⁺ cells and
212 pericellular collagen accumulation was observed (r=0.76, p<0.01, Figure 3D left panel). Although the number of
213 CD163⁺ cells moderately increased at T12 (6±3% vs. 9±4%, p=0.04, Figure 3B), a negative association between
214 CD163⁺ count and pericellular collagen accumulation was found (r=-0.65, p=0.02, Figure 3D right panel). By
215 contrast, the number of CD68⁺ cells decreased between T0 and T12 (17±8% vs. 14±7%, p=0.04, Figures 3C), but
216 was not associated with collagen deposition at T0 or T12.

218 **Major ECM Remodeling at Transcriptomic Level after Weight Loss**

219 As BS-induced weight loss is accompanied by increased collagen deposition without detectable one-year change in
220 SWS, we next characterized transcriptomic signatures of scAT at T0 and T12 in 42 women (Group3). Using a 5%
221 false-discovery rate, we detected 4236 up- and 2989 down-regulated genes (functional annotations see
222 Supplemental Figure 1). We focused our analysis on genes encoding proteins involved in ECM structural
223 components, profibrotic proteins, remodeling, and mechanotransduction. We found differential patterns of gene
224 changes (Figure 4A). Particularly, genes encoding collagen III (COL3A1), collagen VI (COL6A1, COL6A2), and
225 elastin (ELN) were significantly down-regulated, while collagen I (COL1A1) was unchanged. Collagen VI alpha 3
226 chain (COL6A3) was modestly up-regulated. Connective tissue growth factor (CTGF) and secreted phosphoprotein
227 1 (osteopontin, SPP1) were significantly down-regulated. MMP-9, TIMP1, TIMP2, and TIMP4 were also
228 significantly modified. Importantly, some genes previously shown to be stimulated by mechanical stress (11), such
229 as YAP, TEAD2, TEAD3, TEAD4, were not modified after weight loss (p>0.05).

230 During collagen biosynthesis, major post-translational modifications take place and are mediated by important
231 enzymes and chaperones. We found that the expression levels of most of these molecules were decreased at T12
232 (Figure 4B). Finally, we observed a significant down-regulation of genes encoding cross-linking enzymes such as
233 LOX, lysyl oxidase-like 4 (LOXL4), transglutaminase1 (TGM1), procollagen-lysine, 2-oxoglutarate 5-dioxygenase
234 2 and 3 (PLOD2 and PLOD3), suggesting that matrix fibers' cross-linking was decreased post-BS (Figure 4A).
235 These transcriptomic analyses confirm the strong remodeling of scAT following BS and show major transcriptomic
236 modifications of enzymes involved in collagen biosynthesis, cross-linking and degradation.

237

238 **Decreased Cross-linking of Matrix Fibers during Weight Loss Associates with Improved Metabolic** 239 **Phenotype**

240 We next explored cross-linking enzymes and their associations with metabolic phenotypes. We confirmed
241 microarray data by RT-PCR and observed that LOX gene expression was significantly down-regulated at T3 and
242 T12 (Group2) (Figure 5A). This was substantiated by decreased LOX protein staining surrounding adipocytes at T3
243 and T12 (Figure 5B) **using IHC**. By confocal microscopy and SHG in fixed scAT samples in 3 random obese
244 subjects (Group1), we found a trend towards reduced collagen and elastin intensity at T3 (Supplemental Figure 2).
245 Elastin protein at T3 had more twisted structures (Figure 5C), suggesting that scAT might become less rigid after
246 weight loss.

247 We next examined the relationships between one-year changes in cross-linking enzyme expression and that of
248 clinical variables (i.e.T12-T0 variation) in Group3 (Figure 5D). The reduction of LOX gene expression was
249 positively associated with the reduction of BMI, fat mass (kg), adipocyte volume, serum leptin and orosomucoid.
250 Variation of LOXL1 was also associated with BMI, fat mass (kg), leptin, total- and HDL-cholesterol. Our gene
251 expression results suggest that decreased post-BS cross-linked scAT matrix fibers in link with improved weight
252 loss.

253

254 **Increased Collagen Degradation during BS-induced Weight Loss**

255 Our team (7) and others (4) have shown that collagen I and III are more frequently observed in fibrous bundles,
256 whereas collagen VI is surrounding adipocytes. Despite increased scAT collagen accumulation post-BS, we found
257 decreased collagen I and VI staining at T12 (Supplemental Figure 3), suggesting that increased picrosirius-red

258 staining may **also** indicate (at least partially) degraded collagen fragments. We tested this hypothesis by measuring
259 collagen fragments with immunostaining, ELISA and zymography from scAT explants. We observed increased
260 stained degraded collagen I surrounding adipocytes in scAT at T3 and T12 (Figure 5E). Accordingly, the
261 concentration of degraded collagen III (C3M) in scAT at T12 was significantly increased compared to T0 (Figure
262 5F left panel). ProMMP-9 and proMMP-2 entities at 92 kDa and 72 kDa respectively were observed (Figure 5G).
263 Despite individual variability, an increased trend of proMMP-2 at T3 in one non-diabetic obese subject and an
264 increase of proMMP-9 at T3 followed by stabilization at T12 in two others were observed. These changes in
265 proMMPs were not detected in samples from **obese** diabetic subjects (**Figure 5G**). In parallel, newly synthesized
266 collagen III (Pro-C3M) concentration was significantly decreased in obese compared to non-obese subjects and
267 showed a non-significant increase at T3, T12 (Figure 5F right panel).

268

269 **DISCUSSION**

270 Collagen accumulation in white AT is considered as an important pathological alteration associated with
271 several comorbidities of obesity (1,7,9). Our results provide new insights into weight-loss induced AT remodeling
272 **in paired humans individuals before and one-year post-BS. Our results** suggest that picrosirius-red stained
273 collagen in scAT does not always refer to “pathological collagens”, but could be a signature of extensive tissue
274 remodeling and collagen degradation following adipocyte shrinkage during weight loss along with improved
275 clinical, metabolic and inflammatory outcomes.

276 During physiological tissue repair, ECM accumulation is a key regenerative step replacing tissue debris and
277 dead cells (2). In pathological conditions, increased collagen deposition is not always synonymous with deleterious
278 fibrosis. In myocardial injury, different types of fibrosis have been reported according to the progression and
279 history of cardiomyopathies: a reactive “interstitial fibrosis” with ECM deposition in response to deleterious stimuli
280 is considered pathological. Conversely, a “replacement fibrosis” that replaces myocytes after cell damage or
281 necrosis may preserve the structural integrity of the myocardium (25,26). As we did not find any association
282 between adipocyte diameter reduction and pericellular collagen increase, we attribute this increased pericellular
283 collagen to “replacement collagen” that occurs at adipocyte shrinkage sites. This is further supported by our
284 observation of some large parenchyma areas filled with less well-organized collagen. This replacement collagen, as
285 part of the remodeling process, might be an adaptive and physiological phenomenon during weight-loss.

286 Cross-linking is necessary for matrix fibers maturation and stabilization (27) and contributes to increased
287 tissue stiffness. LOX is a major enzyme mediating collagen and elastin cross-linking. A relationship between LOX
288 enzymatic activity and tissue stiffness was established in colorectal cancer and indicated a pivotal role of LOX
289 associated stiffness in driving colorectal cancer progression (12,28). In obese subjects, scAT LOX gene expression
290 is increased (11). Increased perioperative scAT pericellular collagen is associated with increased tissue stiffness
291 measured by AdiposcanTM (9). Moreover, pericellular collagen leads to adipocyte constraints and stimulates genes
292 encoding mechano-sensitive, inflammatory and profibrotic proteins such as CTGF in a 3D model (11). Herein,
293 decreased LOX gene expression and protein, and increased elastin twist structure evaluated by SHG after weight
294 loss clearly suggest decreased cross-linking and relaxed fibers.

295 **ScAT stiffness measured by AdiposcanTM relates to adipose tissue rigidity in severe obesity before**
296 **weight loss and is associated with picosirius-red stained collagens and metabolic alterations (9). To our**
297 **surprise, we found increased post-BS collagen accumulation without significant change in average scAT**
298 **stiffness measured by AdiposcanTM despite large inter-individual variability. These results, associated with**
299 **improved metabolic alterations after BS,** suggest that the major ECM remodeling observed after weight loss
300 might be adaptive. **Two profiles of stiffness changes were observed without significant link with clinical**
301 **parameters, indicating that further studies are required to investigate the potential implication of different**
302 **scAT SWS profiles in BS outcomes in larger populations.** Our results also suggest that transient elastography
303 AdiposcanTM might be more sensitive to severe cross-linked and dense fibrosis (**i.e. “pathological fibrosis”**) as
304 **showed in liver stiffness measurements** (29,30), thus explaining why AdiposcanTM fails to detect small decreases
305 in post-BS stiffness or alternatively to quantify adaptive ECM remodeling (**i.e. less cross-linked and more**
306 **degraded collagens**) not linked to pathological conditions. Therefore, AdiposcanTM might be more appropriate to
307 better stratify obese individuals **before any drastic weight intervention or to non-invasively** predict weight loss
308 outcomes (9), **a feature which needs further study in extended cohorts.** Furthermore, other scAT changes
309 occurring after weight loss might also influence tissue stiffness, such as the amount and types of lipids in adipocyte
310 or scAT vascularization. **In addition,** some genes involved in mechano-transduction pathway YAP/TEAD were
311 unchanged while the downstream profibrotic gene CTGF was down-regulated, suggesting again that weight loss
312 induced increased collagen deposition was not associated with pathological constraint.

313 The transcriptomic study performed before and one-year post-BS confirmed intense tissue remodeling.
314 These results align with other observations of decreased major ECM gene and profibrotic proteins both after short-
315 term BS-induced weight loss (14) or dietary intervention (31). We, herein, suggest that increased picrosirius-red
316 staining is, at least partially, due to increased degraded collagens (collagen I, III) and eventually less newly
317 synthesized collagens (collagen III) as shown by immunohistochemistry and ELISA. Indeed, we found decreased
318 staining of specific collagens such as collagen I and VI. Importantly, we went beyond the transcriptomic results
319 obtained by McChulloch et al who observed only increased post-BS COL6A3 expression but not other collagen VI
320 alpha chains or their protein content (14). Our microarray analysis displayed different expression changes of
321 collagen VI alpha chain: COL6A1 and COL6A2 decreased whereas COL6A3 increased. It is well known that
322 transcriptomic changes of sub-type chains do not always relate to the same changes at the protein level. According
323 to our immunostaining results, we found less collagen VI surrounding adipocytes post-BS.

324 Our zymography analysis in scAT revealed the presence of proMMP-2 and/or proMMP-9 proteins in obese
325 non-diabetic subjects. ProMMPs are the inactive zymogen forms. There are growing evidences of the ability of
326 proMMP-2 and proMMP-9 to directly activate classical signaling pathways involved in cell growth, survival,
327 migration, and angiogenesis (32). In metabolically healthy obese individuals, scAT proMMP-9 zymographic
328 activity is increased, suggesting that proMMP-9 might be linked with better metabolic profile (33). **The fact that**
329 **we did observe a difference in obese diabetic individuals seems to be in accordance with this last point, or**
330 **could also be due to the effect of anti-diabetic drugs.** Exploring the co-expression of proMMPs and TIMPs in
331 the context of scAT remodeling and improved metabolism deserves further consideration.

332 The mechanisms leading to fibrosis synthesis and degradation at the cellular level need to be better
333 delineated in AT. AT macrophages (ATM) are triggers of fibrosis (34). We previously showed that both diet and
334 BS-induced weight loss improve inflammatory profiles despite non-negligible inter-individual variations (14,24,35).
335 Here, we observed increased CD163⁺/CD68⁺ ratio due to increased CD163⁺ cells and decreased CD68⁺ cells during
336 weight loss, a profile of activated state of ATM shifted towards M2 relative to M1, as previously shown after 3
337 months post-BS (24). In addition, CD163⁺ cells before BS associated with pericellular collagen accumulation,
338 indicating a role in the generation of fibrosis in obese scAT. M2 cells have a complex role in tissue repair and
339 fibrosis: besides direct effects of M2 cells on promoting and suppressing collagen synthesis and fibrosis
340 development, M2 cells are inducers of Treg cells, which are implicated in fibrosis suppression and can directly

341 produce MMPs and TIMPs, thus controlling ECM turnover (36). The reason why we found a significant negative
342 association between CD163⁺ cells and collagen accumulation at T12 is unknown, but may suggest a balanced
343 involvement of several cell types during this remodeling process and warrants further exploration. **A number of**
344 **studies have previously described changes of scAT immune cells quantified by IHC before and after weight**
345 **loss (14,24,35). However, due to the clinical difficulties in acquiring sufficient and repeated post-surgery**
346 **scAT surgical biopsy samples in obese subjects during the follow-up, it was hard to compare our IHC**
347 **observation to other methods such as fluorescence-activated cell sorting (FACS) for quantifying immune**
348 **cells infiltration.**

349 Some questions remain unanswered. **Our clinical study aimed at evaluating the changes in scAT ECM**
350 **until one year, the nadir point of post- BS weight loss in most individuals (37).** The kinetic changes (amount,
351 type, cross-linking) of collagen fibers with longer duration of post-BS weight loss, stabilization, or weight regain
352 remains to evaluate. **Some studies showed interesting results. For example, after two years post-BS weight**
353 **stabilization, ex-obese subjects still presented the same amount of picrosirius-red stained scAT fibrosis as morbidly**
354 **obese subjects, despite improvements in adipocyte hypertrophy and inflammation infiltration (38). However,**
355 **this ex-obese group was compared to an independent group of pre-BS obese individuals. Specific**
356 **comparison between two independent groups of patients before and after surgery might induce bias in the**
357 **results due to important inter-variability in AT fibrosis. Therefore, these findings should be confirmed in**
358 **samples from same individuals obtained before and after BS, as we herein assessed. Furthermore,** the type of
359 collagens and cross-linking enzymes were not investigated. **In addition,** obese subjects experience periods of
360 weight fluctuations even post-BS (37) that could possibly subsequently modify their adipose tissue ECM
361 characteristics. We previously showed that 59 subjects who underwent RYGB after an initial failure of gastric
362 banding displayed significantly higher total collagen accumulation than primarily operated subjects (9), suggesting
363 again that weight fluctuations impact on ECM remodeling. **Therefore, it is of interest to pursue the follow-up of**
364 **our obese subjects, who were already investigated at baseline and up until one year, to evaluate longer-term**
365 **scAT remodeling and potential relationships with BS outcomes. In addition, there is hardly any current data**
366 **concerning the change of visceral adipose tissue characteristics. In one human study, obese subjects**
367 **displayed decreased fat diameter in visceral AT as measured by ultrasound (39). In rodent models, mice who**
368 **underwent BS demonstrated decreased infiltration of T-lymphocytes and macrophages in visceral AT (40).**

369 **Further study in these post-BS features in humans would be of major interest. However, there are clinical**
370 **and ethical limitations to such explorations and the development of non-invasive (e.g. imaging) measures are**
371 **indispensable.**

372 In conclusion, this study provides new insights into scAT adaptation during drastic weight-loss and shows
373 that increased picrosirius-red staining is a signature of tissue remodeling with increased collagen degradation and
374 less cross-linked fibers. It will be critical to follow patients during long-term weight loss and to determine the
375 impact of scAT remodeling on metabolic improvements.

376

377 **Acknowledgements.** We are grateful to the patients who contributed to this work and especially those who
378 accepted repeated surgical biopsies during the follow-up. We thank Valentine Lemoine for patients' follow-up,
379 Florence Marchelli for data management, and Rohia Alili for her contribution in bio-banking. We thank Frédéric
380 Charlotte, Annette Lescot and Anne Gloaguen for scAT tissue preparation and picosirius-red staining. We thank
381 Victoria Dubar for helping in immunohistostaining. We thank Claire Lovo, Aurélien Dauphin, and Christophe
382 Klein for performing SHG acquisition and for their help in analysis (Imaging Facilities, Institut du Cerveau et de la
383 Moelle épinière, PitiéSalpêtrière, Paris, France). We thank Brandon Kayser, Institute of Cardiometabolism and
384 Nutrition (ICAN), for editorial/writing support.

499 Legende

500 Table 1

501 Values are expressed as means \pm SD (standard deviation), unless otherwise stated. hsCRP, highly sensitive C-
502 reactive protein; HOMA-IR, homeostatic model assessment-insulin resistance; HOMA-B (%), beta cell function;
503 HOMA-S (%): insulin sensitivity. There are 11 common subjects in Group1 and Group2. For continuous data,
504 repeated ANOVA was used to compare three time points in Group1 and Group2, when p values of ANOVA were
505 <0.05 , Holm-Sidak's parametric multiple comparison test was used to compare each of the two time points;
506 student's t-test was used in Group3. For categorical data, Fisher's exact test was used. * $p<0.05$ when compared to
507 T0 in each group, # $p<0.05$ when compared to T3 in Group1 and Group2. Subjects' baseline characteristics (T0) in
508 three groups were compared by ANOVA for quantitative data and by Fisher's exact test for qualitative data. No
509 significant differences were found except the BS type.

510

511 **Figure Legends**

512 **Figure 1. Study flowchart of 118 obese subjects.**

513 **Three groups** of obese individuals were recruited for scAT exploration at baseline (T0) and during the follow-up
514 after bariatric surgery at 3 months T3 and 12 months (T12). There are 11 common subjects (female n=6) in Group1
515 and Group2 in whom we performed both histological analysis (P-R, IHC) and scAT stiffness measurement
516 (Stiffness). **A sub-group of 14 subjects in Group 2 underwent scAT needle aspiration for RT-PCR analysis.**

517 ScAT, subcutaneous adipose tissue; P-R, Picrosirius-red staining; IHC, immunohistochemistry; SHG, second
518 harmonic generation.

519

520 **Figure 2. ScAT evaluation.**

521 Collagen accumulation in scAT stained by picrosirius-red in one representative obese subject at baseline (T0) (A),
522 3 months (T3) (B) and 12 months (T12) (C) post-BS. Total and pericellular collagen accumulation (D) and
523 adipocyte size (E) at T0, T3 and T12 in 36 obese subjects from Group1. Repeated ANOVA test and Holm-Sidak's
524 parametric multiple comparison test were used, * $p < 0.01$. F, scAT stiffness, shear wave speed (SWS), was
525 evaluated at T0, T3 and T12 post-BS measured by transient elastography in 35 subjects (Group2). Repeated
526 ANOVA test, $p > 0.05$. **G, scAT stiffness trajectories are clustered by K-means for longitudinal data (KmL),**
527 **two major clusters (A and B) of stiffness change are observed. No significant difference of stiffness at T3 was**
528 **observed between these two clusters (Cluster A 0.89 ± 0.33 vs. cluster B 0.86 ± 0.15 , Wilcoxon test $p = 0.63$)**

529

530

531 **Figure 3 Macrophage infiltration in scAT**

532 Evolution of CD163⁺/CD68⁺ ratio (A) and CD163⁺ cells (B) and CD68⁺ cells (C) in scAT evaluated by
533 immunohistochemistry (IHC) at baseline (T0) and 12 months post-BS (T12) in 15 obese subjects from Group1
534 (IHC T0-T3-T12 sub-group). Solid lines represent non-diabetic subjects (n=8), dotted lines represent type-2
535 diabetic subjects (n=7). Pearson's correlation between CD163⁺ cells and pericellular collagen accumulation at
536 baseline (T0) (D left panel) and 12 months after BS (T12) (D right panel), hollow points represent Type-2 diabetic
537 subjects.

538

539 **Figure 4. Transcriptomic signature of scAT ECM genes in obese subjects one year after BS**

540 Gene expression levels from micro-array data in scAT at baseline represented as dotted line (T0) and 12 months
541 post-BS (T12) represented as bars, in 42 women from Group3: A, genes involved in ECM remodeling (matrix
542 fibers, cross linking, profibrotic protein, degradation proteins and adhesion protein) show important changes. B,
543 most genes involved in post-transcriptional modifications of collagen are down regulated one year post-BS. They
544 include i) enzymes involved in the hydroxylation of proline: prolyl 4-hydroxylase; prolyl-3 hydrolase;ii) enzyme
545 involved in glycosylation of hydroxylysine: GLT25D1;iii) chaperon molecules HSP47, GRP94, calexin (CANX)
546 and disulphideisomerase (PDI) (HSPA5, DNAJC10, ERP29, PDIA4, PDIA6) and iv) enzymes involved in N- and
547 C- propeptides of procollagens: ADAMTS1, ADAMTS2, ADAMTS5, ADAMTSL4. By contrast, prolyl-3
548 hydrolase (P3H2, P3H3) and ADAMTS9 genes were up-regulated. Data are presented as changes from baseline.
549 *p<0.05.

551 **Figure 5. Cross-linking of Matrix Fibers and collagen degradation and synthesis in scAT.**

552 A, Lysyl oxidase (LOX) gene expression levels at baseline (T0), 3 months (T3) and 12 months (T12) post-BS in 14
553 obese non-diabetic women from Group2. B, LOX stained by immunohistochemistry in obese and non-obese
554 subjects, X20. C, scAT elastin structure (magenta) was observed by second harmonic generation at T0 and T3 in
555 one representative obese subject among the three, X20. D, correlation heatmap between changes of biochemical
556 parameters and changes of genes regulating cross-linking from T0 to T12 in 42 women from Group3. Correlations
557 between gene expression and changes of HbA1c and glycemia were analyzed separately in non-diabetic (nonDM,
558 n=28) and Type-2 diabetic (DM, n=14) subjects. HOMA-IR, HOMA-B% and HOMA-S% were only analyzed in
559 non-diabetic subjects. Pearson's coefficients of each correlation are represented as blue (negative correlation) or
560 red (positive correlation), * p<0.05. E, degraded collagen I in scAT stained by immunohistochemistry in one
561 representative obese subject at T0, T3 and T12 and one representative non-obese subject. F, degraded collagen III
562 (left panel) and newly synthesized collagen III (right panel) in scAT explant measured by ELISA in 5 non obese
563 (Non Ob) and 10 obese subjects (Group1). Diabetic subjects are in red, * p<0.05. G, analysis of (pro)MMP-2 and
564 (pro)MMP-9 presence in scAT by gelatin zymography **in 3 obese non-diabetic (Ob), 3 obese diabetic (Ob Diab)**
565 **and 2 non-obese subjects. Ob Diab 1 was under metformin at T0, but not treated at T3, T12; Ob Diab 2 was**
566 **under sitagliptin, glimepiride, metformin at T0, metformin at T3, not treated at T12; Ob Diab 3 were under**

567 **insulin, liraglutide, glimepiride and metformin at T0, insulin, metformin at T3, glimepiride and metformin**
568 **at T12.** U937 cells (ATCC CRL-1593.2) stimulated with 100 U/ml recombinant TNF for 48 h were used as
569 positive control. ProMMP-2 (72kDa) and proMMP-9 (92 kDa) were detected as transparent bands on the
570 background of Eza-blue stained gelatin.
