THEDEPTHOFALL BOOLEAN FUNCTIONS

W. F. McCOLL<br>M, S, PATERSON

THE DEPTH OF ALL BOOLEAN FUNCTIONS
by
$W_{0} F$. McColl and MoS.Paterson

Department of Computer Science University of Warwick, Coventry ENGLAND

Abstract It is shown that every Boolean function of $n$ arguments has a circuit of depth $n+1$ over the basis $\left\{f \mid f:\{0,1\}^{2} \rightarrow\{0,1\}\right\}$.

1. Introduction

Spira showed in [ ] that for any $k>0$, there is a nunber $N(k)$ such that if $n>N(k)$ then any $n$ argument Boolean function has a circuit of depth $n+\log _{2} \log _{2} \ldots \log _{2} n$. $\longrightarrow$ k times $\longrightarrow$

Upper bounds on depth for specific values of ${ }^{11}$, given by Preparata and Muller [2], are

| $n$ | for | $n \leqslant 8$ |
| :--- | :--- | :--- |
| $n+1$ | for | $n \leqslant 2^{8}+8=264$ |
| $n+2$ | for | $n \leqslant 2^{264}+264$ |
| etc. |  |  |

Whereas Knuth has shown, by computer analysis, that there are 4 argument Boolean functions requiring depth 4.

In this paper, we describe a construction which yields an upper bound of $n+l$ for all values of $n$.
2. Schemes

Our present constructions, and all previous ones for minimizing depth that we know of, have the property of being "uniform" for all functions of $n$ arguments. The same directed graph with the same assignment of arguments to inputs is used for all the functions, tho necessary variation being only in the assignment of base functions to the nodes. Iupanov's construction for minimizing formila size [3] is notable for escaping this form.

We formalize this restriction in our definition of "circuit scheme" and show that for schemes our construction achieves the optimal depth to within an additive constant.

2

Let

$$
B_{n}=\left\{f \mid f:\{0,1\}^{n} \rightarrow\{0,1\}\right\}
$$

and $\mathrm{Xn}_{\mathrm{n}}=\left\langle\mathrm{x}_{0}, \mathrm{x}_{1}, \ldots, \mathrm{x}_{\mathrm{n}-1}\right\rangle$ be the set of formal arguments we shall use in formulae and circuits.

Definition. A circuit scheme is a connected acyclic directed graph in which nodes have either in-degree 2 (gates) in which case the pair of incoming arcs are ordered, or else in-degree 0 (input nodes) in which case an argument $x_{i}$ is assigned to the node. A formula scheme is a circuit scheme in which all gates have out-degree at most one.

Let $C_{n} \subseteq B_{n}$ and $b \subseteq B_{2}$. A circuit scheme $S$ covers $C_{n}$ over basis b if for each $f \in C_{n}$ there is an assignment of functions from $b$ to the gates of $S$ such that the resulting circuit computes $f$. Figure $I$ shows a formula scheme which covers $B_{3}$ over basis $B_{2}$. This follows from the expansion

$$
f\left(x_{0}, x_{1}, x_{2}\right)=\left(x_{0} \wedge f_{1}\left(x_{1}, x_{2}\right)\right) \oplus f_{0}\left(x_{1}, x_{2}\right)
$$

where $\oplus$ denotes sum modulo $2, f_{0}\left(x_{1}, x_{2}\right)=f\left(0, x_{1}, x_{2}\right)$ and $f_{1}\left(x_{1}, x_{2}\right)=f\left(1, x_{1}, x_{2}\right) \oplus f\left(0, x_{1}, x_{2}\right)$. We have verified that this is the unique formula scheme (to within obvious symmetries) with fewer than five gates that covers $B_{3}$. Its depth of 3 is therefore optimai.

Fig.I.

We prove a lower bound on the depth of schemes by a simple counting argument.

Theorem 1 . Any circuit scheme which covers $B_{n}$ over any basis $b \leq B_{2}$ has depth at least $n-1$.

Proof. A scheme of depth $D$ has at most $2^{D}-1$ gates, and so by varying the assignment to gates from $b$ can cover a set of at most $|b|^{2^{D}-1}$ different functions.

$$
\begin{gathered}
\text { Since }\left|B_{n}\right|=2^{2^{n}} \text { we have } \\
16^{2^{D}-1} \geqslant 2^{2^{n}}
\end{gathered}
$$

$$
\text { which yields } D \geqslant n-1
$$

Note that this argument produces no better bound even when $|b|=2$.

In the next two sections we describe the main result of the paper, a scheme of depth $n+1$ to cover $B_{n}$ over basis $B_{2}$. The first stage is to produce an "approximation" to such a scheme in depth $n$.
3. The approximation of depth $n$.

If $C=\left\langle c_{1}, \ldots, c_{k}\right\rangle \in\{0,1\}^{k}$ and $Y=\left\langle y_{1}, \ldots, y_{k}\right\rangle$, we shall.
write $Y=c$ for $\bigwedge_{l \leqslant i \leqslant k} y_{i}=c_{i}$ and 0 for $\left.<0, \ldots, \infty\right\rangle$. Another abbreviation will be to write $f(Y)$ for $f\left(y_{l}, \ldots, y_{k}\right)$, $g(Y, Z)$ for $g\left(y_{1}, \ldots, y_{k}, z_{1}, \ldots\right)$, etc.

Definition. Given $S=\left\{R_{1}, \ldots, R_{k}\right\}$ where $R_{j} \subseteq X_{n}$ for all $j$, and any $f\left(X_{n}\right)$, we define $g(X n)$, the approximation to $f$ with respect to $S$ by

$$
\begin{aligned}
g\left(X_{n}\right) & =0 \text { if } \exists R_{j} \in S \text { such that } R_{j}=0 \\
& =f\left(X_{n}\right) \text { otherwise }
\end{aligned}
$$

Any function $f(Y, Z) \in B_{k+m}$ may be expressed as a disjunctive expansion about Z by

$$
\begin{gathered}
f(Y, Z)=\bigvee_{C \in\{0, I\}^{m}} \delta_{C}(Z) \wedge f(Y, C) \\
\text { where } \delta_{C}(Z)=1 \text { if } Z=C \\
=0 \text { otherwise }
\end{gathered}
$$

Dually, the conjunctive expansion about $Z$ is

$$
\begin{aligned}
& f(Y, Z)=\bigwedge_{C} \bar{\delta}_{C}(Z) \vee f(Y, C) \\
& \text { where } \bar{\delta}_{C} \text { denotes the complement (negation) of } \delta_{C} .
\end{aligned}
$$

It is evident that $\delta_{C}$ and $\bar{\delta}_{C}$ require formulae of depth only $\left\lceil\log _{2} m\right.$. .

For each $n>3$, we may define sequences of positive integers $<r_{0}, \ldots, r_{p}>$ which satisfy the following conditions, where $S_{m}=\sum_{i=0}^{m} r_{i}$ for all $m$ :
(i) $\quad r_{0}=r_{I}=2$
(ii) $\quad S_{p}=n$
$\begin{array}{ll}\text { (iii) } r_{m} \leqslant 2^{m-2} & \text { for } m>0 \text { and } m \text { even } \\ \text { (iv) } r_{m} \leqslant 2^{m-2}-2^{m-3} & \text { for } m>1 \text { and } m \text { odd }\end{array}$
lor each such $n$, let $p$ be maximal such that,

$$
\frac{p(p+1)}{2}+1<n
$$

We choose the sequence defined by

$$
\begin{aligned}
& r_{0}=2 \\
& r_{i}=i+1 \text { for } p>i>0 \\
& r_{p}=n-S_{p-1}
\end{aligned}
$$

For example if $n=12$ we get $\langle 2,2,3,4,1\rangle$. This sequence satisfies (i)-(iv). The fastest-growing sequence satisfying (i)-(iv) begins, For large $n$, with $<2,2,4,12,256,2^{20}-256,2^{276}, \ldots>$

Given $\left\langle r_{0}, \ldots, r_{p}\right\rangle=\langle 2,2,3,4, \ldots\rangle$ let $R_{0}, R_{1}, \ldots, R_{p}$ be a corresponding partition of $X n$ with $\left|R_{i}\right|=r_{i}$ for all $i$.

We shall describe our construction in terms of formulae rather than in a more abstract way as schemes. It will be clear throughout however that the formulae are uniform.

Theorem 2. For all $f \in B_{n},(n>4)$, there is a formula of depth $n$ for the approximation to $f$ w.r.t. $S=\left\{R_{1}, \ldots, R_{p-1}\right\}$.

Proof. Since $n>4$, then $p>1$. We express $f$ as an expansion about $R_{p}$ which is disjunctive if $p$ is odd and conjunctive if $p$ is even. Fach of the $2^{r} p$ terms in this expansion is expressed in depth $S_{p-1}$ hy using the results and constructions of the following lemma $\square$

For an inductive proof we must incorporate a more detajled specification of the formulae at each stage.

Lemma: Let $R_{o}, R_{1}, \ldots R_{m}(m>0)$ be disjoint sets of arguments with their cardinalities $r_{o, \ldots,}, r_{m}$ satisfying conditions (i), (iii) and (iv) above. Then for any function $f\left(R_{0}, \ldots, R_{m}\right)$, there is a formula for its approximation $g$ w.r.t. $\left\{R_{1}, \ldots, R_{m}\right\}$ consisting of:Case(a): if $m$ is odd, a disjunction of $2^{r^{m}}-1$ subformulae each of depth $S_{m-1}$

Case(b): if $m$ is even, a conjunction of $2^{r} m$ subformulae each of depth $S_{m-1}$ and another subformula of depth $S_{m-2}$.

Proof. We proceed by induction on $m$ using two alternative expansions.

In case (a),

$$
g\left(R_{0}, \ldots, R_{m}\right)=\bigvee_{C \neq 0}\left(\delta_{C}\left(R_{m}\right) \wedge g_{C}\left(R_{0}, \ldots, R_{m-1}\right)\right)
$$

and in case (b),

$$
g\left(R_{0}, \ldots, R_{m}\right)=\bar{\delta}_{0}\left(R_{m}\right) \wedge \bigwedge_{C \neq 0}\left(\bar{\delta}_{C}\left(R_{m}\right) \vee g_{C}\left(R_{o}, \ldots, R_{m-1}\right)\right)
$$

where in each case $g_{C}$ is the approximation to $f\left(R_{0}, \ldots, R_{m-1}, C\right)$ over $\left\{R_{1}, \ldots, R_{m-1}\right\}$.

The validity of these expansions is easily verified.
If $m=1$, then the first expansion is of the required form since both $\delta_{C}$ and $g_{C}$ have depth 1 and so we have a conjunction of 3 formulae of depth 2 . If $m>1$ and $m$ is odd then in the same expansion we may, by the inductive hypothesis, take $g_{C}$ to be a conjunction of $2^{r_{m-1}}-1$ subformulae of depth $S_{m-2}$ and a smaller subformula of depth $S_{m-3}$. Since $\delta_{C}$ is essentially a conjunction of $r_{m}$ arguments and $r_{m} \leqslant 2^{S-2}-2^{S^{m}-3}$, it may be conjoined with the smaller subformula to produce a formula of depth $S_{m-2}$. The resulting conjunction of $2^{r m-1}$ formulae of depth $S_{m-2}$ can be written in depth $r_{m-1}+S_{m-2}=S_{m-1}$. The requirements of case (a) are thereby met.

If $m$ is even then the second expansion is used, the ${ }_{\delta}{ }_{C}$ are themselves of depth $S_{m-2}$ and case (b) is easily satisfied

The lemma may be illustrated with $n=17, m=3$ and the sequence $<2,2,3,10\rangle$.
The resulting approximation $g\left(R_{0}, R_{1}, R_{2}, R_{3}\right)$ is a disjunction of 1023
formulae each of the form:

The leftmost subformula may be given in more detail as:

FIG. 3
$\wedge$
where the base functions associated with certain gates are not defined if they depend on $D$.

Each of the $h_{C}\left(R_{0}, R_{1}, R_{2}\right)$ subformulae are of the form:

FIG. 4

where the leftmost subformula is:

FIG. 5

and the associated base functions depend on $C$.
4. Main Result

It remains to be shown how the approximation $g$ to $f$ over $R_{1}, \ldots, R_{p-1}$ can be used to compute $f$.

Lemma. Suppose $R_{1}, \ldots, R_{k}$ are disjoint subsets of $X n$. For all $f\left(X_{n}\right)$, there exist $f_{l}\left(X n-R_{l}\right), \ldots, f_{k}\left(X n-R_{k}\right)$ such that $g_{k}(X n)=f \oplus \bigoplus_{i=1} f_{i}$ is an approximation to some function w.r.t. $\left\{R_{1}, \ldots, R_{k}\right\}$ Proof. This is by induction on $k$. The lemma holds trivially for $k=0$ 。 Let $k>0$, and suppose the result is true for $k-1$. Then, there exist $f_{1}\left(X n-R_{1}\right), \ldots, f_{k-1}\left(X n-R_{k-1}\right)$ such that for all $i$, $1 \leqslant i<k$, $R_{i}=0 \Rightarrow g_{k-1}(X n)=f \oplus \bigoplus_{i=1}^{k-1} f_{i}=0$

$$
\text { We define } f_{k}\left(X n-R_{k}\right)=0 \text { if } \exists i, l \leqslant i \leqslant k, R_{i}=0
$$

$$
=\left.g_{k-1}\right|_{R_{k}=0} \quad \text { otherwise }
$$

and can verify that $g_{k}$ has the required property

## Main Theorem

For all $n, n \geqslant 1$, there is a formula scheme with depth $n+1$ which covers $B_{n}$ over $B_{2}$.

Proof. Schemes for $B_{1}, B_{2}$ are obvious, while for $B_{3}, B_{4}$ expansions can be made about 1 and 2 arguments respectively to yield schemes of depth 3 and 4. By the previous lemma, any function $f\left(X_{n}\right)$ may be computed as $g_{p-1}(X n) \oplus \bigoplus_{i=1}^{p-1} f_{i}\left(X n-R_{i}\right)$ where $g_{p-1}(X n)$ is an approximation to some function w.r.t. $\left\{R_{1}, \ldots, R_{p-1}\right\}$.

By Theorem 2, any function $f(X n)$ may be approximated w.r.t. $\left\{R_{1}, \ldots, R_{p-1}\right\}$ within depth $n$.

Thus for $n>4$, there is an approximation $f_{0}$ with depth $n$ and we need to "add in" appropriate functions $f_{1}, \ldots, f_{p-1}$ where $f_{i}$ has $n_{i}=n-i-1$ arguments. Whenever $n_{i} \leqslant 4$, a formula for $f_{i}$ is constructed directly, otherwise the present construction is used recursively to yield a formula of depth $n_{i}+l=n-i$.

Thus $f$ is expressed as

$$
f_{o}(X n) \oplus \bigoplus_{i=1}^{p-1} f_{i}\left(X n-R_{i}\right)
$$

or, after reassociation, as

$$
\left.f_{0} \oplus\left(f_{1} \oplus\left(f_{2} \oplus \ldots \oplus f_{p^{-1}}\right)\right) \ldots\right)
$$

Since $f_{i}$ has depth $n-i$ for $i=0, \ldots, p^{-1}$, this represents a formula of depth $n+1$.

Again it is clear that the construction is uniform and thus yields a scheme

## 5. Restricted Bases

The formulae considered so far have used all of $B_{2}$ as the basis. Provided that the basis $b$ permits a scheme to cover $B_{2}$ and contains at least one function from each of the following three types:

| ^-type | $p^{*} \wedge q^{*}$ |
| :--- | :--- |
| v-type | $p^{*} \vee q^{*}$ |
| ©-type | $p^{*} \oplus q$ |

where a starred variable represents either the variable or its complement, the construction can be followed more or less as before, complementing subformulae as necessary to achieve depth $n+2$ 。

An interesting basis is the set which excludes the two $\oplus$-type functions. In using this unate basis we may replace $\oplus$ by

$$
p \oplus q=p \wedge \bar{q} \cdot \vee \cdot \bar{p} \wedge q
$$

In order to fit in the correcting functions efficiently we choose a new sequence

$$
\left\langle r_{0}, r_{1}, r_{2}, \ldots\right\rangle=\langle 2,2,4,6,8,10, \ldots\rangle
$$

so that each $f_{i}$ contains $\underline{2}$ fewer arguments than the previous one. The result is a scheme of depth $n+3$.

For $b$ consisting of one $\wedge$-type function and one $v$-type function we can obtain $n+4$ by taking the unate construction and complementing subformulae as necessary. Conjecture. For any $b \subseteq B_{2}$, if there is a scheme over $b$ which covers $B_{2}$ then there is a constant $c$ such that for all $n$ there is a scheme over $b$ of depth $n+c$ which covers $B_{n}$.

For $b=\{\bar{p} \vee \bar{q}, p\}$ we have, at present, achieved no better than $n+O\left(\log _{2} n\right)$.

We must distinguish the notions of complete bases for formulae and for schemes. For example, $b=\{N A N D\}$ is complete for formulae but obviously no singleton basis can be complete for schemes, hence the condition on $b$ given in the conjecture.

## 6. Conclusion

We have described a uniform scheme for expressing all n-argument Boolean functions in depth $n+1$, and have matched this upper bound with a lower bound of $n-1$ under the restriction of uniformity. For a basis of unate functions only, our upper bound is $n+3$.

In our construction we used a sequence $\langle 2,2,3,4,5, \ldots\rangle$, but a sequence which grows much faster could be used instead. The effect of the choice of sequence on formula size has not been considered but easy counting arguments limit the possible size to within $2^{n-1}$ and $2^{n+1}$ for our method. Lupanov's construction [3] yields formulae of size about $2^{n} / \log _{2} n$, though not of counse using schemes. This raises the following:

Open problem : Does a lower bound of "n-constant" on depth still.
hold when the restriction to schemes is removed?
