Résumé en anglais	Buruli ulcer is a tropical skin disease caused by <i>Mycobacterium ulcerans</i> . Its mode of transmission is not yet clearly understood. We report here a cutaneous ulcer in a European traveler in South America resulting from a coinfection detected specifically for <i>Mycobacterium ulcerans</i> and <i>Leishmania braziliensis</i> DNA with real-time polymerase chain reaction. This observation of a unique cutaneous ulcer raises the issue about possible modes of transmission of those two pathogens by the same vector.
