## **Acknowledgments**

First and foremost, I want to give my deepest thanks to my mentor, Celeste Karch, whose patience, wisdom, and calm guidance has been monumental as I mature into the scientist I am now and sets a high bar for the scientist I hope to be in the future. I would not be here today without your mentorship. Even though my time in the lab is coming to an end, I hope to continue working and collaborating with you in the years to come.

I would also like to thank the members of the Karch lab for sharing with me their wisdom, support, and humor when I needed it the most. It has been both an honor and a delight to call you all my colleagues.

I would like to give thanks to my committee. I always enjoyed the discussions during our meetings and appreciate the valuable advice that guided and pushed this work forward. You also played a critical role in my development and I have nothing but the deepest admiration for you all.

I also want to thank my running buddies. The countless miles we spent together on the roads kept me sane and gave me a necessary respite from the daily grind.

To Bethany, thank you for hearing me endlessly ramble on about my work, for listening to me recite my practice talks countless times, for lending an ear when I had to vent about the latest frustration, and for always having my back. It has meant the world to me.

Finally, I also want to give the deepest thanks to my family. You were there for me at my highest of highs and, most importantly, my lowest of lows. You were my biggest fans and motivators to keep pushing when things got hard, while also making sure I took the time to smell the coffee. At my darkest of moments, you reminded me that there was still light at the end.

I thank the International Genomics of Alzheimer's Project (IGAP) for providing summary results data for these analyses. The investigators within IGAP contributed to the design and implementation of IGAP and/or provided data but did not participate in analysis or writing of this dissertation. Study data were provided by the following sources: The Mayo Clinic Alzheimer's Disease Genetic Studies, led by Dr. Nilufer Taner and Dr. Steven G. Younkin, Mayo Clinic, Jacksonville, FL using samples from the Mayo Clinic Study of Aging, the Mayo Clinic Alzheimer's Disease Research Center, and the Mayo Clinic Brain Bank. Study data includes samples collected through the Sun Health Research Institute Brain and Body Donation Program of Sun City, Arizona.

This work was also funded by BrightFocus Foundation (CMK), the Alzheimer's Association (CMK), NIH U01 AG052411 (AG), R01 AG062359 (CMK), P50 AG005681 (JM, CMK), R56AG067764 (CMK, OH, CC), U01 AG072464 (ST, CMK, OH, MK), UL1 TR002345, NS090934 (DMH), AG047644 (DMH), NS094692 (JML), AG062359 (MK).

This work was supported by access to equipment made possible by the Hope Center for Neurological Disorders and the Departments of Neurology and Psychiatry at Washington University School of Medicine. I thank the Washington University in St Louis Mouse Genetics Core for assistance in generating the Pld3 KO mice. The gRNAs were generated by the Genome Engineering and iPSC Center (GEiC) at the Washington University in St. Louis. I thank the Hope Center Viral Vector Core for generating the AAV8 particles and the Hope Center Animal

Surgery Core for performing the AAV8 injections.

Confocal was generated on a Zeiss LSM 880 Airyscan Confocal Microscope, which was purchased with support from the Office of Research Infrastructure Programs (ORIP), a part of the NIH Office of the Director under grant OD021629. The recruitment and clinical characterization of research participants at Washington University were supported by NIH P50 AG05681, P01 AG03991, and P01 AG026276.

## ABSTRACT OF THE DISSERTATION

Defining the role of rare genetic variants that drive risk and pathogenesis of Alzheimer's disease

By

Matthew James Rosene

Doctor of Philosophy in Biology and Biomedical Sciences

Molecular Cell Biology

Washington University in Saint Louis, 2022

Celeste M. Karch, Chair

Alzheimer's disease (AD) is the leading cause of dementia and is pathologically defined by the aggregation of extracellular amyloid plaques and intracellular neurofibrillary tangles. Rare heritable mutations within the genes for *amyloid precursor protein* (*APP*) and *presenilin 1* (*PSEN1*), and *presenilin 2* (*PSEN2*) cause early onset AD and account for approximately 1% of AD cases. While the majority of AD cases are late-onset (LOAD), which is defined by a markedly more complex genetic architecture that is comprised of many genetic risk factors that influence AD through multiple cellular pathways. The advent of deep sequencing analyses have allowed for the identification of novel risk factors and genetic variants. By identifying these genetic risk factors, characterizing their cellular and molecular function, and then identifying the roles they play influencing AD risk, this knowledge may be leveraged for the development of more effective therapeutics. In this dissertation, I look more deeply into three risk factors: *LMNA*, *RAB10*, and *PLD3*. Through a combination of computational analysis and

functional/biochemical assays, I attain a deeper understanding of the roles of these genes as they affect AD pathogenesis.

The first of these genes, *LMNA*, encodes a nuclear lamin protein that is associated with the accelerated aging condition Hutchinson-Guilford Progeria Syndrome (HGPS). In this condition, a mutation in *LMNA* leads to the production of progerin, which is unable to be processed by *ZMPSTE24* and constitutively incorporates into the nuclear membrane, causing nucleoskeletal dysfunction. In AD, some of these same nucleoskeletal deficiencies have also been observed. Through mRNA expression analysis of laser-captured microdissected neurons, we observe a significant elevation of *LMNA* expression coupled with a reduction of *ZMPSTE24* expression in diseased brains, resulting in more immature, unprocessed prelamin A. When we induced progerin expression in iPSC-derived cortical neurons, we observed disruption in pathways associated with the oxidative stress response as well as the lysosome, which has been associated with AD pathology in the literature.

Further genomic analyses in increasingly larger datasets has led to the identification of genetic variants that protect against AD. One study by our group identified a rare SNP in the 3'-untranslated region (3'-UTR) of *RAB10* (rs142787485). As a Rab GTPase, *RAB10* plays a role in the endo-lysosomal network (ELN), a central pathway to the processing of APP and the production of A $\beta$ . In AD brains, we observe increased levels of *RAB10* mRNA and *RAB10* protein expression. Overexpressing *RAB10* in N2A695 cells increases the ratio of extracellular A $\beta$ 42/40, which is associated with increased pathogenicity. Furthermore, when investigating the rs142787485 SNP, the location of this SNP is predicted to interfere with the binding of multiple miRNAs. However, these predictions still need to be validated through functional and biochemical assays.

In our efforts to better understand AD genetics, there remain challenges posed by genes that remain uncharacterized in terms of their function. One such gene is *PLD3*, a member of the phospholipase D family, but lacks any confirmed phospholipase activity or substrate. Whole exome sequencing of families densely affected by LOAD uncovered the rare variant in *PLD3* p.V232M. Further deep sequencing uncovered additional variants associated with increased disease risk. In our work we find that one particular synonymous variant, p.A442A, activates a cryptic splice site, resulting in the reduced expression of exon 11. Furthermore, studies of AD patients show that *PLD3* is reduced in the neurons of AD brains. When we look at loss of *Pld3* in amyloid model mice, we observe significantly decreased A $\beta$  turnover and altered plaque pathology which we further attribute to reduced microglial plaques, mirroring what has been observed in *Trem2*-deficient amyloid mice. Together, these studies illustrate the critical role of nuclear and ELN function in AD risk and resilience.

# **Chapter 1: Introduction and Overview**

## **1.1 Introduction**

Alzheimer's disease (AD) is a neurodegenerative disease defined clinically by progressive memory decline [1]. AD currently affects more than 44 million people worldwide, and this number is expected to rapidly increase as the population ages (<http://www.alz.co.uk>).

Neuropathologically, AD is characterized by neuronal loss and the accumulation of amyloid plaques and neurofibrillary tangles in the brain, much of which occurs many years before the onset of clinical symptoms [2]. While clinical diagnosis of AD is challenging because it is dependent primarily on observations of family members and caregivers, changes in protein analytes in plasma and cerebrospinal fluid (CSF) and brain imaging, although not widely used in clinical practice, may facilitate AD diagnosis [2]. AD can broadly be defined as early-onset, occurring prior to age 65, or the much more common late-onset, occurring after age 65 (>96.5% of total cases).

## **1.2 Pathology of AD**

AD is clinically characterized by extracellular amyloid plaques and intracellular neurofibrillary tau tangles, both of which occur in sequential order of each other and are requisite for the development of AD [3]. Extracellular amyloid accumulation is characterized by the aggregation of pathogenic amyloid- $\beta$  (A $\beta$ ), a peptide generated through the sequential cleavage of the amyloid precursor protein (APP) by  $\beta$ -secretase and  $\gamma$ -secretase within endo-lysosomal compartments within neurons. A $\beta$  was first isolated from the cerebral amyloidosis of both AD and Down Syndrome patients [4]. While ranging in length from 38-43 amino acids in length, the largest proportion of A $\beta$  peptides are the 40 amino acid long A $\beta$ 40 peptide and the 42 amino acid

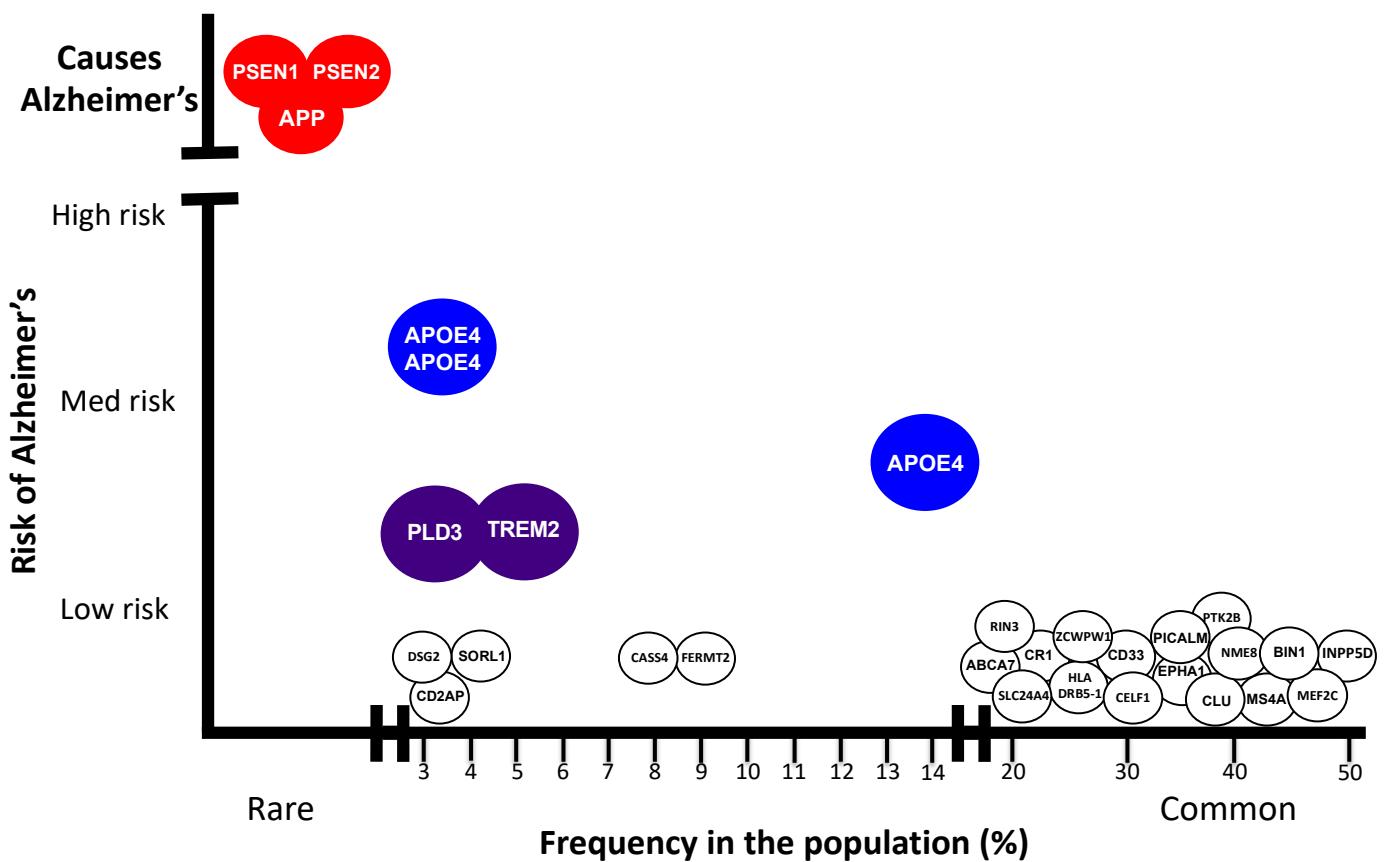

long A $\beta$ 42 peptide to a much lesser degree. Upon its release from the presynaptic neuron, A $\beta$  can be endocytosed by post-synaptic neurons for lysosomal degradation, engulfed by glial cells for lysosomal degradation, or transcytosed across the blood-brain barrier (BBB) and cleared through the cerebrovascular system. A $\beta$  that is not cleared can aggregate into the amyloid plaques, with the A $\beta$ 42 being especially aggregate prone due to increased hydrophobicity of the extra two amino acids. In the timeline of AD pathology and disease progression, accumulation of amyloid plaques is the first occurring pathology in AD, starting ~20 years before the initial onset of cognitive decline [5]. This paradigm, along with discovery of the first mutations within the genes *APP*, *PSEN1*, and *PSEN2* is what ultimately led to the formulation of the amyloid cascade hypothesis [6-8]. While this hypothesis has been called into question over the years, it still stands that amyloid has an important role to play in AD disease pathogenesis and disease progression.

### **1.3 Reconciling the Genetic Architecture of AD with Pathology**

The genetics of early-onset AD (EOAD) are relatively well understood. Autosomal dominant mutations occurring in *APP*, *PSEN1*, or *PSEN2* give rise to a subset of EOAD cases. More than 200 pathogenic mutations have been reported worldwide (<https://www.alzforum.org/mutations>) [9]. Clinically, EOAD mutation carriers exhibit disease onset prior to 65 years of age [10]. Neuropathologically, EOAD and late-onset AD (LOAD) are indistinguishable [11]. Unfortunately, the genetics of LOAD is more complex (Figure 1.1) [12].

Among individuals with LOAD, there is strong evidence for genetic heritability of disease [13-17]. The single largest genetic risk factor for LOAD is *APOE* [18]. *APOE* plays critical roles in cholesterol transport, neuroplasticity, and inflammation [19]. *APOE* regulates A $\beta$  metabolism directly through binding and clearance of A $\beta$  [20] and indirectly via the LRP1 receptor [21]. Moreover *APOE* influences tau-mediated neurodegeneration [22]. Two different

*APOE* alleles,  $\epsilon 4$  and  $\epsilon 2$ , affect risk for AD. Risk for developing AD is 3-fold higher in individuals carrying one copy of the  $\epsilon 4$  allele and 12-fold higher in individuals carrying two copies of *APOE*  $\epsilon 4$  [23]. Conversely, *APOE*  $\epsilon 2$  confers resilience to AD, while the  $\epsilon 3$  allele is considered neutral risk [23].

**Figure 1.1: The complex genetic architecture of AD.** While EOAD has been solely attributed to mutations in the APP metabolism genes *PSEN1/2* and *APP*, LOAD is influenced a broader range of factors that have different cellular functions and exert their own unique influence on AD risk.

Genetic variants that influence risk for AD can be broadly classified into two groups: common and rare. The majority of common variants (minor allele frequency (MAF)  $>5\%$ ) were identified using genome-wide association studies (GWAS).[15] With the exception of variants in

*APOE*, all other common variants have small effect sizes on AD risk (odds ratios=1.08-1.22, 0.73-0.94) [15]. While GWAS variants provide insights into disease processes, none of the common risk variants for AD that have been identified by GWAS have clear functional effects and efforts to identify functional variants in the regions of GWAS variants have largely been unsuccessful.

The advent of next-generation sequencing has enabled the sequencing of whole exomes and genomes, resulting in progressively larger AD datasets and providing insights into the contribution of low frequency (MAF 1-5%) and rare variants (MAF<1%) to the genetic architecture of AD. Using a variety of study designs, multiple rare variants have been identified that affect risk for AD [15, 24-27]. Rare variants typically have much larger effect sizes on disease risk than common variants identified by GWAS. Rare variants are also more likely to occur in coding or regulatory regions and thus are more likely to be functional. Thus, rare variants represent effective therapeutic targets.

Finally, alternative study designs can provide additional insights into the genetics of AD. For example, the use of quantitative endophenotypes (eg, CSF levels protein analytes such as A $\beta$  and tau [28-30]; mitochondrial copy number [31]; metabolic efficiency [32, 33]; measurements of progressive brain atrophy [34]; among others), and the analysis of mitochondrial genomic variation [35] have expanded our understanding of the genetic architecture underlying disease onset and disease course.

#### **1.4 Using the Genetics of AD to Identify Therapeutic Targets**

Genes and pathways that regulate AD pathogenesis may represent viable targets for treating disease. For example, therapies targeting the removal of A $\beta$  or inhibition of A $\beta$

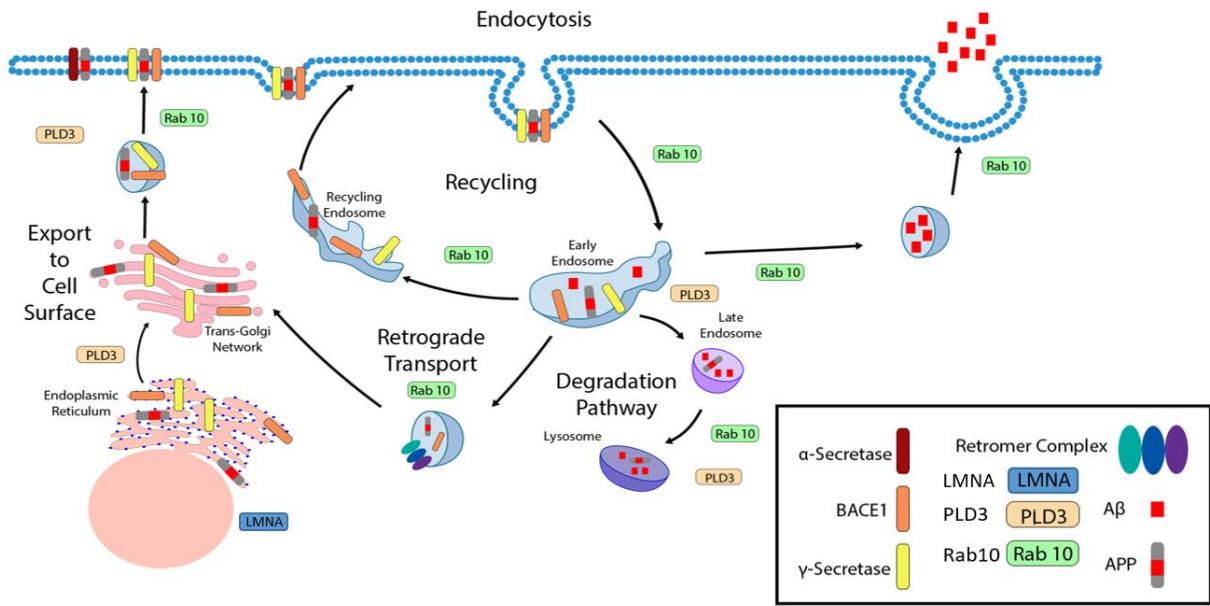

production are currently in clinical trials. These strategies are based on our understanding of the mechanisms by which rare mutations in *APP*, *PSEN1* and *PSEN2* drive AD pathogenesis in EOAD and focus on inhibition of the deposition of A $\beta$  in the brain. Similarly, targeting APOE function has been investigated for its therapeutic capacity [36-38]. AD risk genes implicated in immune function, endocytosis, and lipid biology represent novel avenues of therapeutic development. Unfortunately, to date, more than 90% of all clinical trials have failed. Given the expected increase in disease incidence, developing effective therapeutics is imperative and is highly dependent on better understanding the mechanisms that drive disease. For the remainder of this dissertation, I discuss the role of three genes that have been shown to alter AD risk, *LMNA*, *RAB10*, and *PLD3*, how they influence AD pathology and mechanisms, and their potential as therapeutic targets (Figure 1.2).

## **1.4 LMNA and Nucleoskeletal Integrity in AD**

### *LMNA, HGPS, and premature aging*

In order to gain a deeper understanding of neurodegenerative disease mechanisms, we must look to analogous diseases when parallels present themselves. In Hutchinson-Guilford Progeria Syndrome (HGPS), mutations in the *LMNA* gene, which codes type-A lamins (lamin A and lamin C), results in altered splicing of the *LMNA* mRNA, yielding the truncated *LMNAΔ150* and its protein product progerin. Unable to be cleaved by the zinc metallopeptidase and become defarnesylated, the constitutively farnesylated acts in a dominant negative nature by permanently anchoring into the nuclear membrane and disrupting normal lamina functions and disrupting nucleoskeletal morphology and integrity [39]. Downstream, these defects in nucleoskeletal morphology have broader detrimental effects for the cell both within the nucleus (chromatin disorganization, genomic instability and DNA damage, and abnormal gene expression) as well as

outside the nucleus (mitochondrial dysfunction, oxidative stress, and loss of proteostasis) [40-43], all of which have been also reported within AD.

**Figure 1.2: Cellular Functions of *RAB10*, *PLD3*, and *LMNA*.** Image adapted from Tavana et al [44].

### Laminopathies

The nuclear lamina refers to the structural meshwork that exists within the inner surface of the nuclear membrane, giving nuclei its shape. Comprising of both A-type (lamins A, C, A $\Delta$ 10, and C2) and B-type (lamin B) lamins, expression of the nuclear lamina comes from the *LMNA* and *LMNB* genes. However, besides providing structure to the nucleus, research has also shown that the nuclear lamina serves important roles in the organization of heterochromatin, transcriptional regulation, and nuclear pore positioning and function [39, 45]. This broad range of roles means that dysfunctional lamins can have far-reaching consequences beyond the nucleus. Indeed, mutations in the lamin genes, in particular *LMNA*, have been linked to several serious diseases termed as laminopathies [46].

Of the known laminopathies, the most notable is Hutchinson Gilford Progeria Syndrome (HGPS), a markedly serious laminopathy that results in severe premature aging in children, resulting in death by roughly age 13. With ~90% of cases being caused by the G608G (GGC>GGT) mutation that activates a cryptic splicing site within *LMNA* to yield significantly elevated levels of progerin, a truncated form of prelamin A that is normally found to increase in the skin and liver of normal individuals with age [40, 47-49]. Unlike mature Lamin A, the missing 607-656 amino acids contain the cleavage site for ZMPSTE24, the zinc metalloproteinase that farnesylates prelamin A [47, 50]. Unable to be further processed into mature Lamin A, progerin constitutively congregates at the inner nuclear membrane in a dominant-negative manner, leading to nuclear blebbing [40, 47]. Furthermore, the missing 50 amino acids in progerin are also necessary for the binding of Lamin A to the histone modifications of heterochromatin, resulting in a loss of organization of the peripheral chromatin in the nucleus [51, 52].

### *Laminopathy in AD*

Interestingly, many of the same nuclear defects observed in laminopathies are also observed in AD. In a cohort of collected AD brains, Frost et al., observed tubular invagination in 60% of the neuronal nuclei analyzed, a level 3-fold higher than what was observed in age-matched control brains [40]. Furthermore, a link was proposed that tauopathies may exert an effect on nucleoskeletal integrity by increasing the levels of over-stabilized filamentous actin, which interacts with the nuclear lamina through the LINC (Linker of Nucleoskeleton and Cytoskeleton) complex [40, 53, 54]. When considering the role of nuclear lamina in the organization of peripheral heterochromatin, a link between tauopathies and heterochromatin disorganization can also be reasonably postulated. Additional evidence also shows that tau can

interact with the nuclear pore complex in a manner that can alter nuclear export/import. Based on these presented findings, it becomes apparent that there is a connection between AD and nuclear and Lamin dysfunction. In **Chapter 2**, I further delve into this relationship and the role of *LMNA* in AD and neurodegeneration.

## **1.5 *RAB10*: The protective endo-lysosomal factor**

### *The protective *RAB10* variant in AD*

Common and rare variants have been identified that reduce the risk for AD.[9] Those with the strongest protective effect include *APOEε2* and *APP*-A673T [55, 56]. Thus, genes and pathways involved in increasing AD risk may also confer resilience to disease. In order to identify additional genetic variants that confer resilience to AD, there is a need to develop novel study designs that focus on those individuals carrying protective factors for AD. In one such case, family pedigrees were identified with a statistical excess of AD mortality (ie, families with a higher number of AD deaths than expected relative to similarly sized pedigrees; termed high risk pedigrees). Within these high-risk pedigrees, elderly individuals with genetic risk for AD (i.e., *APOEε4* carriers) but who had escaped AD were evaluated using whole genome sequencing. Ridge et al. identified a rare variant (rs142787485) in the 3'-UTR of *RAB10* that confers resilience to AD [17]. In a cell model of *APP* metabolism, silencing of *Rab10* expression leads to a significant decrease in Aβ42 and the Aβ42/40 ratio, consistent with prior reports.[17, 57] Interestingly, independent of the *RAB10* SNP, individuals with a neuropathologic diagnosis of AD exhibited significantly higher levels of *RAB10* compared with neuropathology-free controls.[17] Thus, genetic and molecular evidence support a role for *RAB10* in AD pathogenesis. While not much work has been published to closely examine this role, in **Chapter**

3, I will discuss some of the proposed mechanisms through which RAB10 may contribute to AD and how the rs142787485 SNP contributes to this.

### **1.7 *PLD3*: A mysterious protein promoting A $\beta$ clearance**

#### *Discovery of rare variants in PLD3*

Through whole exome sequencing of families densely affected by LOAD, a rare genetic variant located within the seventh exon, V232M, was identified in the gene for phospholipase D3 (*PLD3*) and perfectly segregated with disease in two different families. Further deep sequencing of additional unrelated cohorts of AD and control patients further uncovered additional variants that were also significantly associated with disease risk, notably the M6R and A442A variants that were also associated with an increase in disease. Looking beyond variants, *PLD3* is found to accumulate on the amyloid plaques of diseased brains [58]. When analyzing at RNA expression in the brain, it was found that AD brains displayed significantly reduced expression when compared to age-matched controls, with biochemical assays using *in vitro* systems implicating this altered expression to result in an alteration of APP metabolism [15].

#### *A protein without a known function*

*PLD3* is a member of the phospholipase D family, which has seven known members. PLD family members are defined by the presence of two HKD “catalytic domains” [59]. However, of the seven known isoforms, the knockout of *PLD1* and *PLD2* together is sufficient to completely abrogate phospholipase activity [60-62]. To date, *PLD3* has no known substrate or confirmed function. However, some of the published literature have begun to shed some light on its role. On a macroscopic level, *PLD3* has been implicated in myotube formation [63] and, in tumors, is a marker of senescence and plays a role in HIF1 $\alpha$ -dependent lipid metabolism [64, 65]. At the cellular level, *PLD3* has been shown to play a wide range of roles in the endo-

lysosomal network (ELN). Within the endosome, *PLD3* has been proposed to be an endonuclease in immune cells for microbial DNA to generate short oligos for presentation to Tlr9 in mice [66]. In addition, within neurons, PLD3 colocalizes with APP in endolysosomal compartments and also has been postulated to play a role in retromer transport from the endosome, where  $\beta$ - and  $\gamma$ -secretases are rich in concentration, to the Golgi, where their concentration is much lower [67-70]. Finally, evidence both from our group as well as others have been pointed to a role for PLD3 in the lysosome. The *PLD3* promoter contains a CLEAR motif, suggesting that it is a member of the CLEAR network, a family of lysosomal enzymes regulated by TFEB, the master lysosomal transcription factor [71]. Furthermore, PLD3 not only carries a mannose-6-phosphate tag to direct it to the lysosome without being degraded and colocalizes with Lamp2 [72-74], but evidence has also demonstrated that PLD3 is trafficked to the lysosome via the endosome and requires ubiquitination of its N-terminus [66]. While the role of PLD3 in the lysosome is not fully understood, lysosomes in *Pld3*-deficient mouse neurons are increased in size and density, implying a buildup of undigested cargo [75]. Recently, it was reported that within the lysosome, PLD3 exhibits display phospholipase activity [76]. In chapters four and five of this dissertation, all of this will be further discussed and elaborated on at length.

As stated above, the genetics of LOAD is remarkably complex and, while much progress has been made, many factors still yet remain to be identified, and even more are yet to be functionally characterized. However, by better shining a light on the many genes that can influence AD risk, we stand to gain a deeper understand the pathways and mechanisms that drive disease and, by extension, we can better develop therapeutics to slow disease progression or treat the symptoms that result. For the remainder of this dissertation, I will outline and discuss my work on my own efforts to do this very thing for *LMNA*, *RAB10*, and *PLD3*.

## **Chapter 2: LMNA-mediated nucleoskeleton dysregulation in Alzheimer's disease**

## 2.1 Abstract

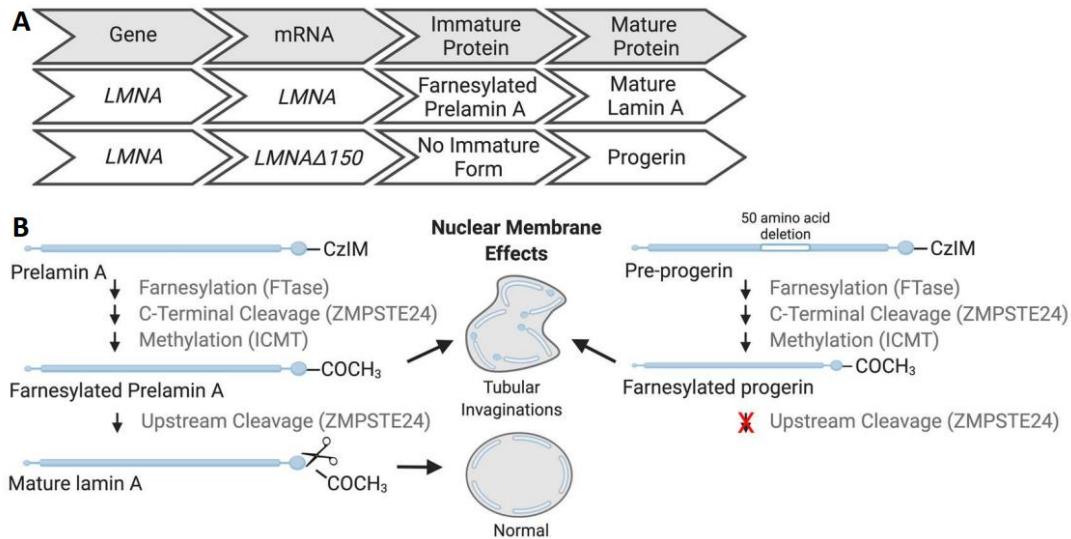

Nucleoskeleton dysfunction has been implicated in Alzheimer disease (AD). Tubular invaginations of the nuclear envelope observed in AD brains are consistent with the accumulation of farnesylated prelamin A (encoded by the *LMNA* gene) that occurs in Hutchinson-Gilford Progeria Syndrome, a premature aging disorder caused by *LMNA* mutations. Proper function of the nuclear membrane is required for neuronal survival and for maintenance of genetic architecture. To determine whether dysregulated *LMNA* expression and prelamin A processing are responsible for nucleoskeleton dysfunction in AD, we performed differential gene expression and network analyses in human AD and age-matched control brains. In AD brains, we observed a significant increase in *LMNA* and a significant decrease in *ZMPSTE24*, which encodes the zinc metallopeptidase protein that defarnesylates prelamin A. We replicated these findings in laser capture microdissected neurons from AD brains, suggesting that the effect is neuronally driven. Thus, high levels of *LMNA* paired with low levels of *ZMPSTE24* could result in the accumulation of farnesylated prelamin A and tubular invaginations in the nuclear membrane. *LMNA*-associated networks were also differentially expressed in AD brains. Genes within the dysregulated *LMNA* network were enriched in lysosomal and chromatin remodeling pathways. We propose that  $\beta$ -amyloid and tau accumulation disrupts prelamin A processing and downstream changes in the nuclear membrane. Alterations in the nucleoskeleton induce genomic instability, loss of proteostasis, and cellular senescence, which may accelerate AD pathogenesis.

## 2.2 Introduction

Alzheimer disease (AD) is a neurodegenerative disorder characterized by extensive neuronal loss and accumulation of extracellular amyloid plaques and intracellular neurofibrillary tangles. Nucleoskeleton dysfunction has also been reported in AD brains [1, 2]. Dysfunction of this kind can cause genomic instability, loss of proteostasis, epigenetic changes, mitochondrial dysfunction, deregulated nutrient sensing and cellular senescence [1, 3-5], all of which have been described in AD [2, 6, 7]. The precise mechanism by which nucleoskeleton dysfunction occurs in AD remains unclear. Thus, identifying the molecular and protein triggers that drive these defects could allow us to target and modify critical phenotypes in AD.

Genetic and cell-based evidence point to a critical role of lamin A in proper nuclear membrane function. Hutchinson-Gilford Progeria Syndrome (HGPS) is a rare premature aging disorder. HGPS is caused by mutations in *LMNA*, the gene that encodes A-type lamins (lamin A and lamin C), activating a cryptic splice site that gives rise to a truncated transcript termed *LMNAΔ150* and its protein product progerin [8, 9]. Under normal conditions, immature lamin A protein (prelamin A) is post-translationally modified at the nuclear membrane by farnesylation, cleavage, carboxyl methylation and excision of the farnesylated residue by the zinc metallopeptidase ZMPSTE24 [10-12]. The *LMNAΔ150* transcript, however, lacks the ZMPSTE24 binding site, leading to accumulation of progerin, a shorter protein with retained farnesyl modification, in the nuclear membrane and subsequent nuclear shape abnormalities, chromatin disorganization, damage to DNA and abnormal gene expression [13-15]. These progerin-induced phenotypes mimic several aspects of normal aging [16, 17]. Deficiency in

ZMPSTE24 function, which results in build-up of farnesylated prelamin A in the nuclear membrane, also causes nuclear distortion and a premature aging phenotype [18-20]. Notably, progerin builds up in the nuclear envelope even in normal cells with aging due to sporadic use of the cryptic splice site, which prevents defarnesylation (Figure 2.1) [9, 16].

**Figure 2.1: Model of lamin A processing.** A. Schematic of lamin A and progerin processing. B. After translation, immature prelamin A is farnesylated, then cleaved by ZMPSTE24 to remove the farnesyl residue and yield mature lamin A. Farnesylated prelamin A or progerin are unable to properly incorporate into the nuclear lamina but are retained in the nuclear membrane resulting in tubular invaginations.

The changes observed in nuclear envelope morphology in AD brains are consistent with the build-up of farnesylated prelamin A or progerin, which could indicate an AD-associated change in the regulation of lamin A expression and processing [1, 2]. Here, we show that AD pathology is associated with disrupted *LMNA* and *ZMPSTE24* expression, which, in turn, brings about changes in lamin A protein levels and subsequently alters molecular networks associated with proteostasis and chromosome remodeling. Thus, nucleoskeleton defects caused by altered

lamin A processing may contribute to downstream pathways that promote neurodegeneration and AD pathogenesis.

## **2.3 Materials and Methods**

### *Human Subjects*

The Washington University IRB reviewed the Charles F. and Joanne Knight Alzheimer Disease Research Center (Knight ADRC) Neuropathology Cores (from whom the brains were obtained) operating protocol as well as this specific study and determined it was exempt from approval. In the state of Missouri, individuals can give prospective consent for autopsy. Our participants provide this consent by signing the hospital's autopsy form. If the participant does not provide future consent before death the DPOA or next of kin provide it after death. All data were analyzed anonymously.

### *Laser Capture Microdissected Neurons*

The GSE5281 dataset was obtained from laser capture microdissected neurons from AD and control brains (Table 2.1) [21]. Brain samples from individuals of European descent that were collected from Washington University, Duke University, and Sun Health Research Institute were included in the study. Samples were obtained from the entorhinal cortex, hippocampus, medial temporal gyrus, posterior cingulate, superior frontal gyrus, and primary visual cortex and were clinically and neuropathologically confirmed AD (N=33) or controls (N=14). RNA expression was measured using an Affymetrix GeneChip for gene expression. To analyze RNA expression, the log transformed expression values were analyzed with brain region, age, and gender as covariates as previously described [22].

### *Mount Sinai Brain Bank*

Mount Sinai Brain Bank (MSBB) RNA sequencing (RNAseq) study was accessed from the Accelerating Medicines Partnership – Alzheimer’s Disease (AMP-AD) portal (syn8690199; accessed December 2017). We examined gene expression in the parahippocampal gyrus (PHG; BA36) of brains with a neuropathologic diagnosis of AD (N=135) and neuropathology free, age matched controls (N=85; Table 2.1). RNAseq was performed using the Illumina HiSeq 2500 System with an average of 38.7 million reads per sample [23, 24]. The gene count data generated from RNAseq analysis was imported into RStudio, an integrated development environment that supports R, a programming language for statistical computations. Differential gene expression analysis was performed using the package *DESeq2* with covariates including age at death, post-mortem interval, sex, and RNA integrity number.

### *Mayo Clinic Brain Bank*

Mayo Clinic Brain Bank (Mayo) RNAseq study was accessed from the AMP-AD portal (syn6090813). We examined gene expression in the temporal cortex of brains with neuropathologic diagnosis of AD (N=82), pathologic aging (N=29), and elderly control brains that lacked a diagnosis of neurodegenerative disease (N=80; Table 2.1). Pathologic aging is defined as the presence of amyloid plaques (CERAD neuritic and cortical plaque densities of 2 or more) without neurofibrillary tangles (Braak NFT stage of less than 3 and no other co-morbid pathology) [25]. These brains were part of the Mayo Clinic RNAseq cohort, as described previously [25]. RNAseq was performed using Illumina HiSeq 2000, 101-base-pair, paired-end sequencing at the Mayo Clinic Genomic Core Facility. After applying quality control steps, raw read counts were normalized according to conditional quantile normalization (CQN) using the

Bioconductor package. Differential gene expression comparing AD to controls used a “Simple Model.” In this model, multi-variable linear regression analyses were conducted in R, using CQN normalized gene expression measures and including age-at-death, gender, RNA integrity number (RIN), brain tissue source, and flowcell as biological and technical covariates.

### *Frontotemporal Lobar Dementia-tau (FTLD-tau) Brains*

Insular cortex from autopsy-confirmed, FTLD-tau with a causative mutation at *MAPT* p.R406W (N=2) and age-matched, cognitively normal control brains (N=2) were obtained from the Knight ADRC (Table 2.1) [26]. RNAseq paired end reads were generated using Illumina HiSeq 4000 with a mean coverage of 80 million reads per sample. FastQC was applied to the data to evaluate sequencing quality [27]. Data were aligned to GRCh37 primary assembly using STAR (ver 2.5.2b) [28]. Reads alignment were further evaluated by applying Picard CollectRnaSeqMetrics (ver 2.8.2) to examine reads distribution on the genome [29]. The gene count data generated from RNAseq analysis was imported into RStudio. Differential gene expression analysis was performed using the package *DESeq2* with covariates including age at death, post-mortem interval, sex, and RNA integrity number as previously described [30].

**Table 2.1:** Study demographics

Dataset	Brain Region	N	Male (%)	Mean Age at Death	AD	PA	FTLD-MAPT	Control
MSBB	PHG*	220	36	83.3	135	0	0	85
GSE5281	EC, HPC, MTG, PC, SFG, PVC**	47	53.2	79.9	33	0	0	14
Mayo [25]	Temporal Cortex	191	50.2	80.2	82	29	0	80
Knight ADRC [26]	Insular Cortex	4	50	69.5	0	0	2	2

\*PHG, Parahippocampal Gyrus. \*\*, EC, Entorhinal Cortex; HPC, Hippocampus; MTG, Medial Temporal Gyrus; PC, Posterior Cingulate; SFG, Superior Frontal Gyrus; PVC, Primary Visual Cortex. AD, Alzheimer's disease. PA, pathological aging. FTLD-tau, frontotemporal lobar dementia with tau inclusions.

### *Developmental expression of LMNA and ZMPSTE24*

Developmental gene expression for *LMNA* and *ZMPSTE24* were evaluated using a spatial and temporal microarray expression data set focusing on the prenatal brain [31]. These exon-level expression data originate from 25 areas and 9 layers (fetal mitotic and post-mitotic zones) of the human brain sampled in 40 clinically normal postmortem brains of diverse ethnicity that span 32 consecutive periods of neurodevelopment and adulthood from 8 post-conception weeks (PCW) to 40 years (for additional details see <http://www.brainspan.org/>). We downloaded expression values, calculated using z-score normalization. Using line and bar plots we visualized patterns of gene expression, across region and over time (from 8 PCW to 40 years of age). Using a repeated measure analysis of variance (ANOVA), we evaluated whether gene expression patterns over time showed statistically significant differences between brain regions.

### *Network Analysis*

*LMNA*-associated gene networks were defined as those genes that were significantly differentially expressed in response to forced progerin expression (GEO: GSE52431) [5]. Briefly, these expression profiles were generated in a prior study of Parkinson disease models by differentiating human induced pluripotent cells (iPSC) into dopaminergic (mDA) neurons using a modified Dual-SMAD protocol [5]. RNAseq was performed in 70-day iPSC-derived mDA neurons expressing nuclear-GFP or progerin-GFP [5].

Briefly, paired-end reads were generated on an Illumina HiSeq2000. Reads were mapped to the human genome (Hg19) using STAR 2.3.0e [28] using default mapping parameters, and read counts were assessed using HTSeq. Differentially expressed genes were identified with limma voom in R. A low read count filter was used such that all samples were required to contain non-zero read counts for a gene to be assessed. Differentially expressed genes were identified using a fold change cut off of +/- 2 and a Bonferroni adjusted p-value of 0.05.

Forced progerin expression in iPSC-derived mDA neurons resulted in 113 up-regulated and 1,318 down-regulated genes (FDR<0.05; Supplemental Table 2.1) [5]. We used these genes to construct a *LMNA* network in the Mayo and MSBB-PHG datasets. In the Mayo dataset (Table 2.1), 1,273 genes were identified. In the MSBB dataset (Table 2.1; PHG), 693 genes were identified. Subsequent analyses were then focused on those genes that were differentially expressed in the same direction across all three datasets: iPSC-derived mDA, Mayo, and MSBB.

### *Pathway Analysis*

To identify enrichments in gene ontology associated with the genes within the *LMNA* network, we used the Consensus Path Database (CPDB). Gene ontology analyses were performed using CPDB (Release 31; <http://cpdb.molgen.mpg.de/>) [32, 33]. CPDB compares gene ontology terms between background and candidate gene sets using the hypergeometric test and generates p-values that are corrected for multiple testing using FDR. We used the default background gene set, which includes 18,043 genes. Biological, cellular and molecular gene ontology terms were included in a single analysis.

### *GWAS*

Single Nucleotide Polymorphisms (SNPs) within 10kb of *LMNA* and *ZMPSTE24* were identified using NCBI. To determine whether these SNPs were associated with AD risk, we used the International Genomics of Alzheimer's Project (IGAP), a large two-stage study based upon genome-wide association studies (GWAS) on individuals of European ancestry. In stage 1, IGAP used genotyped and imputed data on 7,055,881 SNPs to meta-analyze four previously-published GWAS datasets consisting of 17,008 Alzheimer's disease cases and 37,154 controls (The European Alzheimer's Disease Initiative–EADI the Alzheimer Disease Genetics Consortium–ADGC The Cohorts for Heart and Aging Research in Genomic Epidemiology consortium–CHARGE The Genetic and Environmental Risk in AD consortium–GERAD).

### *Lamin A and ZMPSTE24 protein analyses in human AD brains*

Parietal lobes from autopsy-confirmed AD (CDR 3; N = 3) and age-matched, cognitively normal control (CDR 0; N = 3) brains were obtained from the Knight ADRC. Brains were homogenized in RIPA lysis buffer (50mM Tris pH 7.6, 2.5mM EDTA, 150mM NaCl, 0.5% SDS, 1.0% Triton X-100, 0.5% sodium deoxycholate, protease inhibitor cocktail) on ice by sonication and centrifuged at 14,000g for 10 minutes at 4°C as previously described [34]. The resulting supernatants were analyzed for total protein levels by bicinchoninic acid assay (Thermo Fisher). Standard SDS-PAGE was performed with 10μg of protein for each sample using NuPAGE Novex 4-12% Bis-Tris Protein Gels (Thermo Fisher) in NuPAGE MOPS SDS Running Buffer (Thermo Fisher). Samples were boiled for 5 min in Laemmli sample buffer prior to electrophoresis [35]. Proteins were subsequently transferred onto Immobilon-P polyvinylidene fluoride (PVDF) Membrane, 0.45μm (Millipore) in Tris-Glycine buffer with 20% methanol. Immunoblots were stained with Ponceau S solution (0.1 % (w/v) in 5% acetic acid) to evaluate total protein. Immunoblots were probed with antibodies to lamin A/C (Santa Cruz sc-376248

1:200), or lamin B2 (Abcam ab8983 1:500). Primary antibodies were detected with goat anti-mouse IgG (H+L) HRP secondary antibody (KPL 074-1806 1:6000). Immunoblots were exposed with Pierce ECL Western Blotting Substrate (Thermo Fisher) on a G:BOX Gel Documentation System (Syngene). Band intensities were quantified using GeneTools software (Syngene) manual band quantification. Band intensities were normalized to quantified levels of Ponceau S staining and then expressed relative to the average band intensity of control samples.

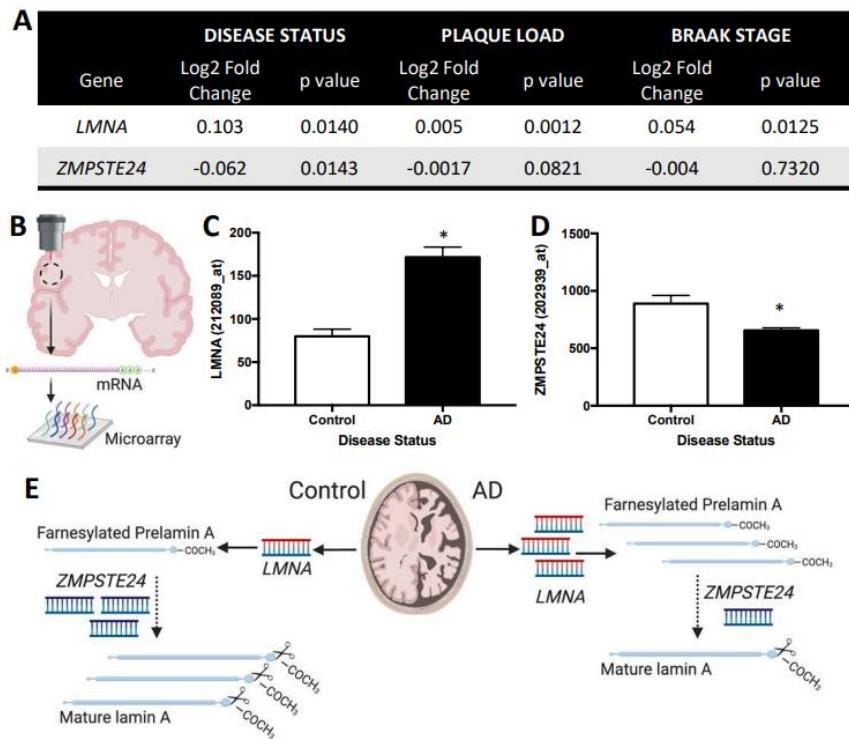

## 2.4 Results

### *LMNA and ZMPSTE24 are dysregulated in AD brains*

To determine whether *LMNA* expression is altered in AD, we analyzed publicly available transcriptomic data generated from a large collection of neuropathologically defined AD and control brains (MSBB). In the parahippocampal gyrus of AD brains, a region affected early in disease pathogenesis, we observed a significant increase in *LMNA* expression and a significant reduction in *ZMPSTE24* (Figure 2.2A). To begin to understand the contribution of AD pathology to lamin A processing, we examined the correlation between *LMNA* and *ZMPSTE24* with plaque and tangle load in human brains. *LMNA* was significantly positively correlated with plaque load and tau Braak stage in the parahippocampal gyrus (Figure 2.2A). Conversely, *ZMPSTE24* was marginally negatively correlated with plaque load, but not statistically significant (Figure 2.2A). In control brains, *LMNA* and *ZMPSTE24* are expressed at similar levels across the cortex (Appendix 1).

When interpreting gene expression data in tissue homogenates from brains with neurodegenerative disease, changes in gene expression may be driven by the cellular composition of the tissue (e.g. extensive neuronal loss) [36]. To replicate our findings and to

begin to understand the cell-type specific impact of *LMNA* and *ZMPSTE24* expression in AD, we examined a publicly available dataset containing RNA expression data from laser capture microdissected neurons from AD and age-matched, control brains (Figure 2.2B) [21]. Consistent with our findings in tissue homogenates from MSBB, we found that *LMNA* was significantly elevated (Figure 2.2C;  $p=9.79\times10^{-4}$ ) and *ZMPSTE24* was significantly reduced (Figure 2.2D;  $p=1.0\times10^{-3}$ ) in neurons isolated from AD brains compared with neurons isolated from neuropathology free control brains. These findings suggest that the impact of AD on *LMNA* and *ZMPSTE24* occurs in neurons.

**Figure 2.2: *LMNA* and *ZMPSTE24* expression are altered in AD brains.** A. *LMNA* and *ZMPSTE24* gene expression are associated with disease status, plaque load (amyloid), and Braak Stage (tau) in brain homogenates from AD and control brains. Parahippocampal gyrus (BA36; MSBB). B-D. *LMNA* and *ZMPSTE24* expression are altered in neurons isolated from AD brains. B. RNA expression was evaluated in laser capture microdissected

neurons isolated from AD and control brains (GSE4281). C-D. Graphs of mean expression (AU)  $\pm$  SEM. C. *LMNA* expression is significantly elevated in AD neurons.  $p=9.79\times10^{-4}$ . D. *ZMPSTE24* expression is significantly reduced in AD neurons.  $p=1.0\times10^{-3}$ . E. In AD brains, increased *LMNA* expression coupled with decreased *ZMPSTE24* may result in an accumulation of immature, farnesylated prelamin A. \*  $<0.05$ .

To determine whether amyloid plaques are sufficient to trigger dysregulation of *LMNA* progressing, we examined *LMNA* and *ZMPSTE24* expression in the temporal cortices of brains with pathologic aging [37]. Pathologic aging is defined as the presence of amyloid plaques (CERAD neuritic and cortical plaque densities of 2 or more) with minimal neurofibrillary tangle burden (Braak NFT stage of less than 3 and no other co-morbid pathology) [25]. Interestingly, we found that *LMNA* was significantly reduced in brains with pathologic aging ( $p=0.01$ ), while *ZMPSTE24* levels were unchanged ( $p=0.69$ ; Table 2.2). Thus, these findings suggest that the observed effects of *LMNA* and *ZMPSTE24* are not solely  $\beta$ -amyloid dependent.

**Table 2.2:** *LMNA* and *ZMPSTE24* expression in brains with Pathology Aging (amyloid plaques) and FTLD-tau (tau tangles)

	Pathologic Aging		FTLD-Tau	
Gene	Fold Change (Log2)	p value	Fold Change (Log2)	p value
<i>LMNA</i>	-0.40	0.0126	1.25	7.60E-03
<i>ZMPSTE24</i>	0.03	0.6970	-0.92	1.51E-04

To determine whether tau aggregation is sufficient to alter lamin A processing, we measured *LMNA* and *ZMPSTE24* expression in FTLD-tau brains [30]. In brains with FTLD-tau caused by autosomal dominant mutations in *MAPT* p.R406W, we observed a significant increase

in *LMNA* ( $p=7.6\times10^{-3}$ ) and a significant decrease in *ZMPSTE24* expression ( $p=1.51\times10^{-4}$ ; Table 2.2).

### *Prelamin A accumulates in AD brains*

We predict that the molecular phenotypes of increased *LMNA* and decreased *ZMPSTE24* that we observed in AD brains result in lamin A dysregulation at the protein level (Figure 2.2E). To test whether our molecular observations lead to a change in the total levels of mature lamin A protein, we measured lamin A in tissue homogenates from AD and control brains (Figure 2.4). Lamin A protein levels were significantly lower in AD brains compared with control brains (Figure 2.4). Of the two protein products that *LMNA* encodes, lamin A requires sequential processing to produce a mature form of the protein that can be normally incorporated into the nuclear lamina, while lamin C does not. As a control, we evaluated lamin C and lamin B2 protein levels and found that these nuclear proteins were unchanged across the brain samples (Figure 2.4). Together, these findings point to a specific effect on lamin A processing in AD brains (Figure 2.4) and as a result, altered ratios of lamins which can change the mechanophenotype of the nuclear membrane [38].

**Figure 2.3: Lamin A protein levels are altered in AD brains.** Autopsy confirmed AD (CDR 3; N=3) and control (CDR 0; N=3) parietal brain tissue were analyzed by SDS-PAGE and immunoblotting. A. Immunoblotting of

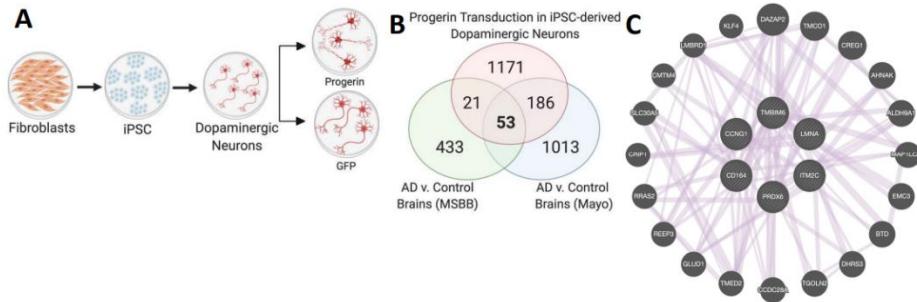

human control and AD brain tissue with antibodies specific to mature lamin A, lamin C, and lamin B2. B.

### *The LMNA network is dysregulated in AD brains*

We next sought to determine whether genes associated with *LMNA* were dysregulated in AD brains. To do this, we constructed a supervised *LMNA* network using publicly available data from a stem cell model in which a mutant form of *LMNA*, progerin, was expressed in iPSC-derived mDA neurons (Figure 2.5A) [5]. Forced progerin expression resulted in 113 upregulated genes and 1,318 downregulated genes compared to iPSC-derived mDA neurons expressing GFP (FDR<0.05; Appendix 1) [5]. Importantly, forced progerin expression resulted in a significant increase in *LMNA* ( $\beta=9.38$ ;  $p=1.33\times 10^{-5}$ ; 82y mDA neurons; Appendix 1).

To determine whether genes that are altered in response to progerin expression were also differentially expressed in AD, we next extracted these 1,431 genes from two publicly available transcriptomics datasets of AD and control brains (MSBB and Mayo Clinic). In the MSBB dataset (PHG), 74 genes were significantly differentially expressed between AD and control brains in the same direction as the iPSC-derived mDA neurons (FDR<0.05; Appendix 2). In the Mayo Clinic dataset (temporal cortex), 239 genes were significantly differentially expressed between AD and control brains in the same direction as the iPSC-derived mDA neurons (FDR<0.05; Appendix 2). In total, 53 genes were differentially expressed in AD brains in the same direction in Mayo Clinic and MSBB datasets and in iPSC-derived mDA neurons (Figure 2.5B; Table 2.3; Appendix 2).

**Figure 2.4: LMNA-associated genes are disrupted in AD brains.** A. *LMNA* networks were defined as those genes altered by expression of progerin in human iPSC-derived dopaminergic neurons [5]. B. Overlap in genes altered by progerin expression *in vitro* and differentially expressed (FDR<0.05) in the same direction in AD versus control brains from two independent datasets (MSBB and Mayo). C. Relatedness of genes significantly elevated in the presence of progerin and in AD brains. Purple lines indicate prior evidence of co-expression.

The six genes that were significantly upregulated in response to progerin treatment and elevated in AD brains (Table 2.3) were highly co-expressed with one another (Figure 2.5C) and were enriched in pathways associated with lysosomal function and apoptotic signaling (Table 2.4). Genes that were downregulated in response to progerin treatment and reduced in AD brains were enriched in pathways associated with chromatin remodeling and nuclear division (Table 2.4). Together, these studies suggest that dysregulation of lamin A processing may be central to the chromatin and lysosomal abnormalities that are characteristic in AD.

#### *Genetic association with AD risk*

Candidate gene studies have previously implicated *LMNA* in AD risk [39-41]. To determine whether common variants in *LMNA* or *ZMPSTE24* contribute to AD risk, we extracted all SNPs in the 10kb region around *LMNA* and *ZMPSTE24*, and we then determined whether these SNPs were associated with risk for AD in IGAP Stage 1 [42]. We identified 133 SNPs near *LMNA* and present in the IGAP Stage 1 dataset; however, no SNPs were significantly associated with AD risk (Appendix 3). Past candidate gene studies implicated rs505058 near *LMNA* in AD risk; however, in IGAP Stage 1, rs505058 was not associated with AD risk ( $p=0.3578$ ). Similarly, of the 52 SNPs near *ZMPSTE24* and present in the IGAP Stage 1 dataset, we failed to observe any SNPs significantly associated with AD risk (Appendix 3). Together, these findings suggest that the observed dysregulation of lamin A processing occurs at the protein rather than the genetic level, which is consistent with previously observed sporadic use of the cryptic splice site [9, 16].

## 2.5 Discussion

AD is defined neuropathologically by the presence of amyloid plaques and neurofibrillary tangles. However, the underlying cellular and molecular mechanisms connecting disease pathology to neurodegeneration and cognitive decline are still not clearly understood. In our study, we demonstrate an association between lamin A-mediated nucleoskeletal dysfunction and AD. We also provide evidence demonstrating that lamin A misprocessing may influence other well-established AD-related pathways.

Nuclear membrane integrity is largely dependent on the highly controlled processing of lamin A. The *LMNA* transcript is translated into immature prelamin A, which is post-translationally modified with a farnesyl group. The zinc metallopeptidase ZMPSTE24 then cleaves this farnesyl group, producing mature lamin A [9, 43]. Interestingly, we observe an imbalance in the key components of this pathway with the elevation of *LMNA* and a reduction in *ZMPSTE24* expression. Together, this can cause a reduction of mature lamin A protein in the brain, leading to an accumulation of nuclear, immature prelamin A which constitutively interacts with and induces irregularities in the nuclear membrane [44].

Genomic integrity and global gene expression are linked to nuclear membrane integrity. In *Drosophila* and mouse models of tauopathy, defects in nuclear morphology were associated with oxidative stress, DNA damage, and loss of heterochromatin [1, 2]. Heterochromatin regulates gene expression. Global relaxation of heterochromatin can lead to aberrant gene expression [45], which has been described in AD. We aimed to more clearly define genes that are downstream of lamin A dysfunction and also change during AD pathology. Importantly,

genes upregulated due to altered lamin A processing and in AD brains are enriched for lysosomal function. The nucleus plays a critical role in lysosomal function. Nutrient sensing between the lysosome and the nucleus control energy metabolism [4]. Lysosomal biogenesis is regulated through transcription factor EB (TFEB) translocation from the cytosol to nucleus in a calcium-dependent manner [46]. Nuclear calcium is a potent regulator of gene transcription, and nuclear defects can significantly alter this signaling pathway. Moreover, nuclear calcium plays a central role in acquired neuroprotection by promoting the build-up of a neuroprotective “shield” through the induction of synaptic activity and by guarding against excitotoxic damage and classical apoptosis [47-50]. In addition, many calcium regulated genes are implicated in the protection of hippocampal and cortical neurons [47, 49-51]. Together, these findings suggest that dysregulation of lamin A processing may be upstream of the well-described lysosomal dysfunction during AD pathogenesis.

Growing evidence points to some mechanistic link between nuclear defects and AD. In a recent study, as many as 60% of nuclei from AD brains display nuclear invaginations [1]. Our data further builds on this by suggesting that the association between nuclear defects and AD is driven by accumulation of pathological tau. This association is consistent with previous reports that also show lamin-mediated nucleoskeletal dysfunction in *Drosophila* and mouse models of tauopathy. Specifically, *Drosophila* expressing tau<sup>R406W</sup> exhibit nuclear deformities along with a decrease in mature lamin protein [1, 52]. Tau-transgenic mice and *Drosophila* display a senescent-like phenotype along with other nuclear defects such as abnormal morphology, dysfunctional nuclear pores, loss of heterochromatin, and changes in gene expression [1, 2, 6, 53]. These defects may occur by altered actin and microtubule dynamics in the cytoskeleton. Both fibrillar-actin (F-actin) and microtubules interact with the nuclear lamina through the

nuclear-envelope-spanning linker of nucleoskeleton and cytoskeleton (LINC) complex such that changes to the cytoskeleton also disrupt the nuclear lamina [1, 44]. In iPSC-derived neurons from *MAPT* mutation carriers, microtubule and actin-mediated deformation of the nucleus is observed with microtubule filaments invading the nucleus through the tubular invaginations [54]. Thus in model systems and human brain tissue, tau-induced alterations in the actin and microtubule cytoskeleton lead to nuclear invaginations containing mislocalized nuclear pores, disrupting nucleocytoplasmic transport [1, 44, 54-56]. Thus, the lamin A processing defects we describe could be driven by tau pathology.

Here, we leveraged data from progerin-transduced iPSC-derived neurons in order to define those genes that change upon disrupted lamin A processing [5]. Miller and colleagues demonstrated that progerin expression was sufficient to capture aging and disease-associated phenotypes that were absent in the naïve cells [5]. This was an important breakthrough in overcoming the relative immaturity of neuronal cultures derived from iPSC [57]. Yet, an important question remained: does altered lamin A processing truly model diseases related to aging? We identified a number of genes that were differentially expressed in this iPSC model due to progerin expression that were also differentially expressed in AD brains in a similar manner. Additionally, these genes were enriched in pathways previously implicated in AD, such as lysosomal dysfunction, apoptosis, and nuclear function. Additionally, another gene of interest that we identified was *SLC30A5*, which codes for a zinc transporter [58, 59]. Zinc transporters have been previously implicated as potential therapeutic targets due to both differential expression in AD as well as brain zinc dyshomeostasis also being linked to AD progression [60]. The effect on *SLC30A5* expression in AD is currently unknown [60], but considering that we find this gene to be altered after forced progerin expression, this finding implies the possibility

that this zinc transporter may have a regulatory role on ZMPSTE24 function and subsequently on *LMNA* processing. Taken together, these results support the notion that forced *LMNA* expression could be used to model aging *in vitro*.

While our study provides evidence for the association of dysfunction of lamin A processing with AD, there remain some important questions. While the mutation known to cause progerin expression in HGPS, *LMNAΔ150*, results in disrupted nuclear integrity in the hippocampal neurons of transgenic mice, neurodegeneration is not observed in HGPS patients [61-63]. It has been proposed that a microRNA miR-9 represses *LMNA* expression in the brain [44, 61-63]. However, we and others demonstrate that *LMNA* transcripts and lamin A protein levels are highly abundant in human brain tissue [64]. HGPS patients may succumb to cardiovascular disease prior to demonstrating neurological effects [44]. Alternatively, given progerin-associated toxicity is increased in the presence of wild-type lamin A [65], it is conceivable that specific inter-lamin interactions might occur in AD patients and result in greater neurotoxicity. Indeed, lamin A may be just one of the lamins that contributes to nuclear defects in AD. Interestingly, it has been demonstrated that lamin B-mediated dysfunction occurs in both tau-transgenic *Drosophila* and mice as well in AD brains [1, 44, 61]. Changes in the relative levels and processing of individual lamins are known to contribute to abnormal nuclear structure and function [44]. Progerin disrupts the normal homotypic biding of A-type and B-type lamins leading to abnormal A-B heteropolymers [18]. Further, changes in the ratio of A and B lamins can significantly alter the mechanical properties and stiffness of the nuclear membrane, leading to alterations in several downstream functions including heterochromatin organization and cell signaling [66]. Moreover, failure to assemble an appropriate nuclear lamina can signal apoptosis [67]. Abnormal nuclear morphology and altered trafficking between the nucleus and cytoplasm

has also been described in Huntington's disease, amyotrophic lateral sclerosis, and FTLD [68-71]. Hence our observations of increased expression of *LMNA* and potential deficits in processing through reduced *ZMPSTE24* in affected AD brain tissue are consistent with alterations in the structure of the nuclear envelope and nuclear lamina and far-reaching effects on gene expression, cell signaling and behavior.

## Conclusions

Here, we show that *LMNA* and *ZMPSTE24* expression are disrupted in AD, which leads to changes in lamin A protein levels and alters molecular networks associated with proteostasis and chromosome remodeling. Thus, nucleoskeleton defects induced by lamin A processing abnormalities may contribute to downstream pathways that promote neurodegeneration and AD pathogenesis. Together, these findings provide compelling evidence for new therapeutic avenues.

## **Chapter 3: RAB10: a protective factor in AD**

### **3.1 Abstract**

Research into Alzheimer's disease (AD) has revealed a complex genetic architecture that comprises a multitude of genes across many different pathways. Furthermore, each of these differing risk factors exert different affects on AD risk. In a 2017 study by our group, a rare SNP in the 3'-untranslated region (3'-UTR) of *RAB10* was found to confer AD resilience in individuals who would normally be at higher risk of disease. A Rab GTPase, *RAB10* regulates subcellular trafficking within the endo-lysosomal network (ELN) a pathway central to APP metabolism. We find that, in AD, RAB10 protein is elevated, which is shown in *in vitro* models to alter the A $\beta$ 42/40 ratio in a manner that promotes protein aggregation and plaque formation. While the rare SNP, rs142787485, appears to have no influence on mRNA expression as a whole or on an allele specific level, we hypothesize that it instead affects post-transcriptional gene expression through the interference of miRNAs, with at least 5 miRNAs that bind at the SNP site and all of which are differentially expressed in AD. While this remains to be replicated *in vitro*, these findings, along with what has been published in the literature, presents interesting opportunities to the field of AD medicine for potential therapeutics against disease.

### **3.2 Introduction**

Understanding the genetic architecture of AD can provide critical insights into genes and pathways that drive disease risk, and this has been a major focus of genetic studies in the AD field. However, genetic architecture may also include variants, genes and pathways that confer resilience to AD. While understanding variants that increase risk allow us to better understand disease mechanisms, understanding protective variants also allow us to better understand successful aging without dementia [1]. In addition, due to the complex nature of AD genetics, successful therapeutics of many individual cases of LOAD may very well require a deep understanding of both risk and protective variants.

This is further demonstrated by a case study of an individual from the largest autosomal dominant AD (ADAD) kindred who carried the *PSEN1* E280A variant but remained cognitively normal until developing mild cognitive impairment (MCI) at well into her seventies, 30 years beyond her estimated age at onset [2]. Whole exome sequencing showed that, while this individual did indeed carry the *PSEN1* mutation, she also carried two copies of the rare *APOE3* R136S variant, known as the Christchurch mutation (*APOE3ch*), which was identified in select patients with hyperlipoproteinemia type III (HLP-III) [2, 3]. These findings serve to demonstrate how a protective variant can counteract a disease-driving mutation, resulting in a normal aging phenotype.

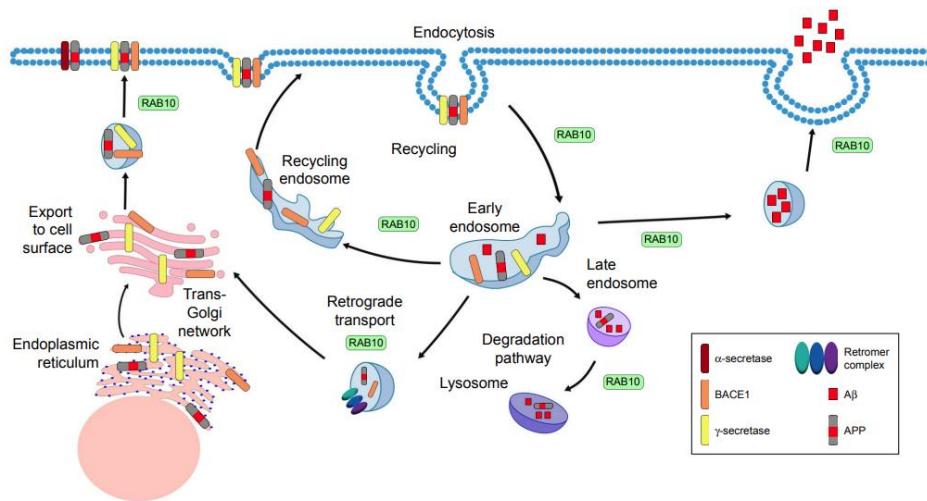

RAB10 is a member of the RAB family of small GTPases, which are key regulators of vesicular trafficking. RAB proteins are cyclically controlled. RAB activation requires a GDP-GTP exchange that is facilitated by RAB guanine nucleotide exchange factors [4]. This requires

phosphorylation at Thr73, which is mediated by Leucine-rich repeat kinase 2 (*LRRK2*), a protein kinase associated with Parkinson's disease [5, 6]. Unlike most of the other RAB proteins, which have relatively specific roles within intracellular transport, RAB10 is relatively unique because it carries out a wide variety of functions and has multiple subcellular localizations [7].

*Rab10* plays essential functional roles in development: mice are embryonic lethal when both alleles are deleted [8]. In addition, RAB10 plays a role in maintenance and regulation of endoplasmic reticulum (ER) morphology [9-11]. When RAB10 is mutated or constitutively inactive (e.g. GDP-locked), the ER contains more cisternae, suggesting that RAB10 plays a critical role in maintaining and/or generating tubule extension and fusion in the ER [10]. RAB10 function has also been linked to neuronal morphology and polarization, playing a critical role in axonal development and dendrite arborization [12, 13]. During neuronal development, RAB10 associates with plasmalemmal precursor vesicles, which are linked to kinesin 1 via c-Jun N-terminal protein kinase-interacting protein 1 [14]. Together this complex mediates anterograde transport of RAB10-positive vesicles to axonal tips, promoting axonal growth [14]. Thus, RAB10 function is critical for proper neuronal function.

RAB10 has been linked to many roles involved in intracellular transport (Figure 3.1). RAB10 plays a role in endocytic recycling. In *C. elegans*, *rab10* is required for AMPA-type glutamate receptor recycling in postsynaptic membranes [15]. RAB10 is likely functional upstream of RME-1/EHD, a protein involved in recycling endosome tubulization and endosome function [16-18]. RAB10 is expressed at the interface of early endosomes and recycling endosomes. These structures are morphologically defective in *rab-10* mutant *C. elegans* models [16, 18]. RAB10 is required for endosomal recruitment of CNT-1 [19]. This likely contributes to biogenesis and/or maintenance of recycling endosome compartments. RAB10 could also play a

role in promoting the maturation of early endosomes to recycling endosome. RAB10 is also involved in protein degradation. RAB10 and RAB3A are essential for lysosomal exocytosis and plasma membrane repair [20, 21]. RAB10-mediated lysosomal secretion is also found to play a role in the cellular response to stressed lysosomes [5]. RAB10 associates with lipid droplets [22]. Complexes of RAB10-EHBP1-EHD2 promote autophagic engulfment and degradation of lipid droplets [23]. Thus, these functional roles for RAB10 in recycling and degradation make it an interesting candidate protein in AD pathogenesis.

**Figure 3.1:** Diagram of APP trafficking and the role of RAB10 in these intracellular transport pathways.

RAB10 is involved in transport of proteins from the early endosome to the Trans-Golgi Network (TGN), where it may also function in the retromer pathway [24]. The retromer complex consists of Vps26, Vps35, Vps29, SNX1, SNX2, SNX5, and SNX6 [25]. The retromer complex regulates transport of protein cargo from endosomes to the TGN by the retrograde pathway or to the cell surface through the recycling pathway [26].

In order to form the amyloid plaques that define a primary component of AD pathology, the transmembrane APP must first be processed into A $\beta$  peptides. APP is thought to be retrieved

from the cell surface and trafficked to the early endosomes where it is initially cleaved by β-site APP-cleaving enzyme 1 (BACE1) to generate a C-terminal fragment (β-CTF) [27, 28]. The β-CTF fragments are then trafficked via retromer-dependent transport to the TGN, which facilitates further cleavage by γ-secretase to produce Aβ40 [29]. The retromer complex and its receptors can transport APP and BACE1 from endosomes to the TGN, ultimately regulating production of Aβ [26]. The retromer complex sorts APP and BACE, either through direct or indirect binding to the transmembrane adaptor protein SORLA [30]. Interestingly, common variants in the gene that encodes SORLA have been associated with AD risk [31]. Thus, genes that are involved in retromer function may influence AD pathogenesis and represent promising therapeutic targets.

Retromer complex dysfunction promotes APP accumulation in neurons and Aβ production. In addition, the retromer also appears to have a differential effect on Aβ isoforms, with evidence that retromer dysfunction alters Aβ40 secretion, which results in increasing the Aβ42/40 ratio [32]. In mouse models, reduction of a single component within the retromer complex, Vps26, is sufficient to increase soluble Aβ and APP [33]. Stabilization of the retromer in human induced pluripotent stem cell-derived neurons using the pharmacological chaperone R33 has been shown to significantly reduce the phosphorylation of Tau in a manner that correlated with, but ultimately independent of, Aβ production [34].

In 2017, our group sought to identify genes that conferred resilience upon otherwise high-risk individuals. To this end, we selected individuals who were at least 75 years of age, cognitively normal, and carried at least one copy of *APOE ε4*, a genotype that carries a significantly elevated risk of AD [35]. These individuals were determined to be “AD resilient”. Through this analysis, a genetic SNP in the 3'-untranslated region (3'-UTR) of *RAB10*, rs142787485 that was linked to AD resilience [35].

An RNAi screen of RABs that modify APP processing revealed that the silencing of *RAB10* reduces A $\beta$  without altering sAPP $\beta$  levels [36]. The LRRK2-RAB10 signaling pathway also causes an overproduction of A $\beta$  [6]. In this chapter I describe the link we discovered between *RAB10* and sporadic AD as well as some of the working hypotheses we have regarding how the rs142787485 ameliorates AD risk.

### **3.3 Materials and Methods**

#### *Patient Consent*

Brains were collected post-mortem following written informed consent from the donor. The Washington University School of Medicine Institutional Review Board and Ethics Committee approved the informed consent (IRB 201104178, 201306108). The consent allows for the use of tissue by all parties, commercial and academic, for research but not for human therapy.

#### *Protein extraction and Western blot of human brain tissue*

Small sections of tissue were cut from the parietal lobe of frozen brain cross sections donated by AD patients and cognitively normal individuals. 10 volumes of lysis buffer (50 mM Tris, 150 mM NaCl, 2 mM EDTA, 0.01% NP40, and 0.5% Triton X100, 1:100 protease inhibitor) were added to the tissue samples based on weight (to 0.1 g tissue, add 1 mL of lysis buffer) before the samples were sonicated 3 times for 30 seconds each. Samples were then pelleted at 14,000xg at 4°C for 10 minutes before the supernatant was collected. Protein concentration was assayed through a BCA and 20 ug of protein was run on a 4-12% bis-tris gel (10-well) (Invitrogen) in MOPS buffer (Life Technologies). The protein was then transferred to a 0.45  $\mu$ m PVDF membrane activated in methanol using 1x tris-glycine buffer supplemented with

20% methanol. Membranes were then probed with  $\alpha$ -pRAB10 (ab230261 [MJF-R21]; 1:200) or  $\alpha$ -RAB10 (ab237703 [MJF-R23]; 1:1000) at 4°C overnight. Blots were then washed and probed with goat-anti-rabbit secondary antibody (Seracare; 1:5000.) for 2 hours. Bands were visualized with either Lumigen (Lumigen) for pRAB10 or SuperSignal™ West Pico PLUS (Thermo Scientific).

### *Preparation of cDNA*

Tissue samples cut from human brains were dissolved in Qiazol lysis reagent (Qiagen) and mRNA was extracted with a phenol/chloroform extraction. The concentration of the mRNA was assayed and converted to complementary DNA (cDNA) through a reverse transcription PCR using the High Capacity cDNA Reverse Transcription kit (Thermofisher Scientific).

### *qPCR*

For the standard Taqman assays, 10 ng of cDNA is loaded with and run using the PerfeCTa FastMix II qPCR master mix (QuantaBiosciences) and Low Rox (QuantaBiosciences). RAB10 was targeted using the Hs00794658\_m1 TaqMan assay (Thermofisher Scientific). The qPCR was run using the QuantStudio 12k Flex Real-Time PCR thermocycler (ThermoFisher) using the Comparative CT method and the standard default cycling settings.

To assess whether rs142787485 had any allele specific effects on *RAB10* expression, cDNA from the parietal lobe of eight individual heterozygous carriers of the rs142787485 SNP were obtained and analyzed with a Kompetitive allele specific PCR (KASP) (LGC Genomics). Differential Ct (dCt) was obtained by comparing Ct values for both alleles from each sample. Three technical replicates were used for each individual and the dCts were averaged. Genomic

DNA (gDNA) from each individual was also used as an internal control. Differential expression across the minor and WT alleles were analyzed through Student's t-test.

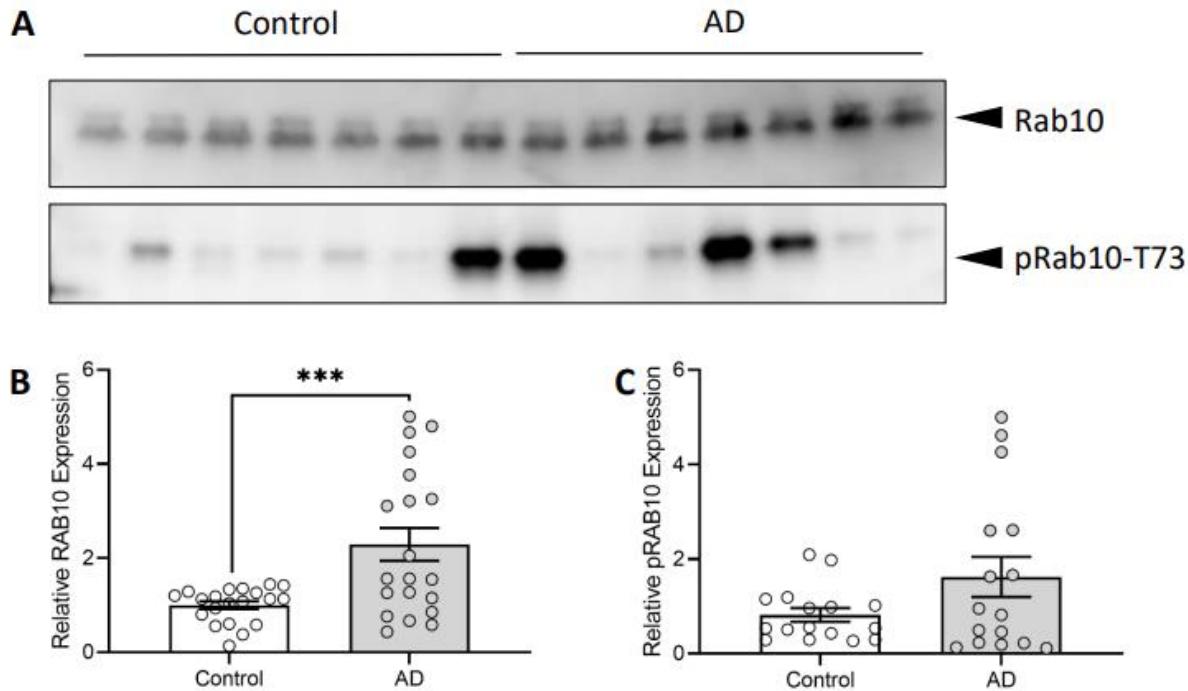

### *miRNA analyses*

To identify potential miRNA binding sites affected by rs142787485, the SNP was entered into the miRSNP database. From the six miRNAs given in the readout, only has-miR-378h was excluded since its affinity was only predicted to decrease in the context of the rs142787485 SNP. The remaining five miRNAs were then cross-referenced with the TargetScan database to identify the type of interaction and miRDB to identify the binding site in the 3'-UTR. To examine the relative expression of these different miRNAs in the context of AD by looking at four different online datasets: GSE16759 (parietal lobe tissue from AD [n=4] and control brains [n=4]) [37], GSE63501 (RNAseq from AD brains [n=6], tangle-prominent demented brains [n=3], and control brains [n=7]) [38], GSE46131 (temporal neocortex gray matter tissue from AD brains [n=5], demented with Lewy Bodies brains [n=4], hippocampal sclerosis of aging brains [n=4], frontotemporal lobar demented brains [n=5], and non-demented brains [n=2]) [39], and GSE48552 (prefrontal cortex tissues from late stage AD brains [n=6] and early stage AD/control brains [n=6]) [40].

## **3.4 Results**

### *RAB10 is elevated in sporadic AD*

Due to its role in subcellular vesicle transport, RAB10 is expressed in all cell types in the brain. However, in brains affected by LOAD, there was a significant increase in the level of expressed Rab10 protein (Figure 3.2A and 3.2B).

**Figure 3.2: RAB10 protein expression is elevated in AD brains.** A. representative Western blot of parietal brain tissue from case control and AD patients. B and C. Quantification of (A) for relative RAB10 protein expression (B) and RAB10 phosphorylation (C). Graphs display standard error of mean. \*\*\* p<0.0005. Analyzed by Student's two-tailed t-test.

Rab10 cycles between its inactive, GDP-bound role and its active, GTP-bound role. When inactive, Rab10 is bound by guanine dissociation inhibitors (GDIs). GDIs extract inactive Rab proteins from their target membranes and bind them in the cytosol. However, upon phosphorylation by leucine rich repeat kinase 2 (LRRK2), a genetic risk factor for Parkinson's Disease, GDI is dissociated from Rab10 and is able to be inserted into the target membrane where it can be activated with the addition of a GTP by a guanine exchange factors (GEFs) [41]. However, beyond Parkinson's, this phosphorylation event may represent a pathological feature in the brains of AD patients [6]. Immunoblotting of parietal brain tissue shows marginal elevation of Rab10 phosphorylation (Figure 3.2A and 3.2C; p=0.0822). pRab10-Thr73 was

observed to co-localize with neurofibrillary tangles in AD brains as well as with granulovascular degeneration, neuropil threads, and dystrophic neurons [6]. Double immunofluorescence staining of these structures further revealed positive staining for phosphorylated tau. However, this co-localization of pRab10-Thr73 and phosphorylated tau was not complete, with some instances showing neuropil threads or dystrophic neurons containing only phosphorylated tau or pRab10-Thr73. Interestingly, dystrophic neurons near amyloid plaques stained positive for pRab10-Thr73, while the amyloid plaques themselves were negative for pRab10 [6]. Total Rab10 staining, however, did not differ between AD and control brains [6]. Thus, while pRab10-Thr73 is associated with AD pathology, it remains unclear whether this represents excess activation or aberrant function of Rab10.

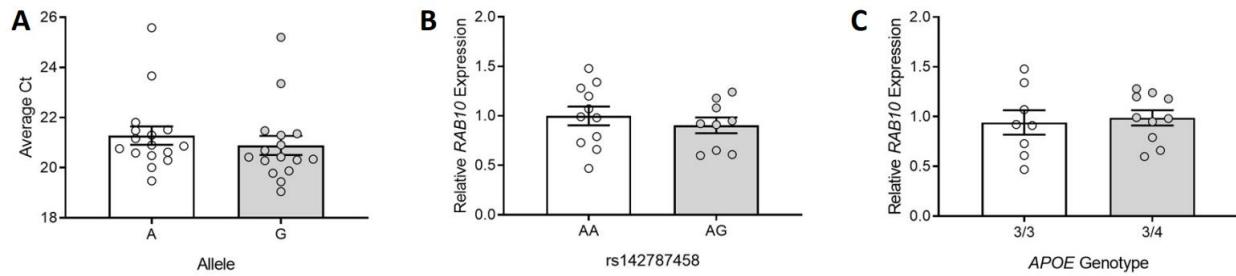

*Rs142787485 SNP is not differentially expressed*

Among AD resilient individuals, a rare SNP in the *RAB10* 3'-UTR was found to be significantly associated with a decreased risk of LOAD (OR=0.69 [0.47-0.99]; p=0.028; MAF [controls/cases]=0.045/0.031), in the presence of at least a single copy of the harmful *APOE4* isoform [35]. Existing outside the coding exons of the mRNA transcript, rs142787485 has no effect on the amino acid coding of the final protein. Indeed, data also shows that there is no difference in relative expression of *RAB10* mRNA in the context of the rs142787485 variant (Figure 3.3A and 3.3B).

*Rs142787485 may alter miRNA-mediated post-transcriptional regulation of RAB10*

Alternatively, the 3'-UTR is a common binding site for many different protein complexes and molecules that regulate post-transcriptional expression, with a notable example being micro

RNAs (miRNAs). MiRNAs are endogenous peptides of non-coding RNAs, spanning roughly 20–22 nucleotides in length. In molecular biology, miRNAs serve a key role in post-transcriptional regulation by mainly inhibiting translation of protein from the mRNA or outright facilitating the degradation of the transcripts [42]. For some time, miRNAs have mostly been researched in the context of cancer, but a growing number of studies has also begun to implicate these miRNAs in AD, with the field showing much promise for both the future development of therapeutics as well as for another type of diagnostic biomarker [43]. By looking at miRNA expression in AD patients, it was in fact observed that many miRNAs that targeted genes associated with A $\beta$  production were differentially expressed, such as miR-29a/b and miR-107, which both target the  $\beta$ -secretase BACE1 [44, 45].

**Figure 3.3: *RAB10* expression is not changed in the context of either the rs142787485 or the *APOE* genotype.**

A. Allele specific expression in the both the wildtype *RAB10* allele (A) and the SNP allele (G) in rs142787485. B. Relative expression of *RAB10* between wildtype (AA) and single allele carriers (AG) for the rs142787485 SNP. C. Relative *RAB10* between individuals with either the neutral *APOE3/3* genotype or the higher pathogenic *APOE3/4* genotype. Graphs display standard error of mean. Analyzed by Student's two-tailed t-test.

The location of the rs142787485 SNP in the 3'-UTR of the *RAB10* gene led us to question whether miRNA-mediated regulation may be affected. To investigate this, the rs142787485 SNP was plugged into the online tool miRSNP [46], which identifies miRNA binding sites that correlate with particular SNPs and predicts the effect of the SNP on binding affinity using a

variety of different algorithms. This includes generating a ranking of miRNA target sites at SNP loci using a machine learning method, miRSVR, which trains a regression model for the features of the binding duplex, the local context features, and the global context features to generate a down-regulation score [47]. Using this tool, six miRNAs were predicted to be affected by the rs142787485 SNP (hsa-miR-369-3p, hsa-miR-374a-5p, hsa-miR-374b-5p, hsa-miR-374c-5p, hsa-miR-378h, and hsa-miR-655). For five of the six miRNAs, the protective *RAB10* SNP is predicted to prevent, or break, the interaction between the miRNA and the *RAB10* transcript, while the interaction between the sixth miRNA (hsa-miR-378h), is only predicted to decrease in affinity [46].

Furthermore, miRNAs have been implicated in multiple instances to play a role in neurodegeneration. As discussed earlier in Chapter 2, *LMNA* is regulated by miR-9 [48], while in AD, APP is targeted by multiple miRNAs that are blocked by identified genetic variants [49]. For *RAB10*, two of the predicted variants, hsa-miR-369-3p and hsa-miR-655, were both identified to be downregulated in AD along with *RAB10* [37-40, 50] (Table 3.1). Therefore, one hypothesis is that rs142787485 is providing protection against AD by disrupting the binding affinity of select miRNAs. Of course, there are some limitations with this hypothesis. Using the Mayo Clinic Brain Bank, it is shown that *RAB10* is upregulated in AD which is associated with an increase in the A $\beta$ 42/40 ratio in the brain, which is more likely to result in toxic plaque formation [35]. Therefore, it seems unlikely that a protective SNP would reduce disease risk by interfering with the binding of miRNA that serve to keep expression down. However, until further experimental work is done, more will have yet to be seen. In addition to miRNAs, the 3'-UTR also serves as a binding site for proteins that also carry out post-transcriptional regulation. These RNA binding proteins (RBPs) bind the 3'-UTR and recruit various effectors [51].

Therefore, there is a possibility that rs142787485 also influences *RAB10* expression through differential binding of RBPs to the 3'-UTR. However, further research is required to further explore this.

**Table 3.1:** Relative expression of various *RAB10*-targeting miRNAs across different studies.

### 3.5 Discussion

In a 2012 study, a coding variant for *APP* (A673T) was identified from whole genome sequencing data from 1,795 Icelanders [52]. Since then, more variants have been discovered across many different genes, including, but not limited to, *APOE*, *SORLI*, *ABCA1*, and *MS4A* [1].

Novel genes and pathways that contribute to the pathogenesis of AD provide insights into strategies to prevent or treat the disease. The amyloid hypothesis, which proposes that the accumulation of A $\beta$  triggers the cascade of events that lead to AD, has been the focus of AD therapeutic development for decades. The development of anti-A $\beta$  therapeutics remains the primary approach to treating AD based on our current understanding of the earliest features of this disease [53]. In this review, we emphasize the importance of *RAB10* in the processing of

APP and the production of A $\beta$ . The function of RAB10 in intracellular trafficking and evidence that a reduction of *Rab10* results in a reduction of the A $\beta$ 42/40 ratio makes inhibition of RAB10 a potential therapeutic avenue.

There are several existing strategies for therapeutic inhibition of a gene product. Potential technologies for targeting of RAB10 are small molecules, antibodies, and antisense oligodeoxynucleotide technologies. For each of these approaches the challenge of delivery across the blood brain barrier (BBB) is a significant one [54]. A molecule with high lipid solubility and molecular mass less than 400Da generally can diffuse across the BBB. These criteria limit the classes of small molecules that can be considered as potential therapeutic molecules for AD. Generally, the BBB does not permit the crossing of many antibodies to achieve an adequate therapeutic concentration without severe peripheral consequences. Several approaches have been developed to deliver antibodies to the brain. Bispecific antibodies have been developed that leverage the Transferrin receptor to successfully increase BBB penetration [55, 56]. In addition, antibody analogs that can cross the BBB are in development (Patent #EP3309171). However, even if successful across the BBB could be achieved, the targeting of intracellular proteins by these antibodies also poses a significant challenge. Antisense oligonucleotides do not readily cross the BBB [57]. However, at present, intrathecal bolus injection is an effective method for ensuring distribution in neurons and glial cells in the brain [58].

Approaches to the development and delivery of small molecule therapeutics are mature and the path, and pitfalls, are well established. Small molecules are effective enzyme inhibitors, receptor ligands, or allosteric modulators. The nature of small molecule activity can make it difficult to find the balance between efficacy and side effects when treating humans [54]. Despite these challenges, small molecule drug development has seen many successes and greater than

90% of existing therapeutics use small molecules. Small GTPases similar to RAB10 have been successfully targeted using small molecules in the past. One important use is the development of molecules to block oncogenic properties of the RAS protein to treat cancer [59]. Recent discoveries about the structure of small GTPases and advances in targeting strategies have further increased efforts to use these important proteins as therapeutic targets [60]. Targeting approaches, including interference with nucleotide binding, inactivation by irreversible covalent modification, inhibition of GTPase-GEF interactions, inhibition of GTPase-Effector interactions, and stabilization of GTPase-Protein Complexes have been successful and are reviewed by Cromm et. Al. 2015 [60]. While challenges regarding specificity and crossing the blood brain barrier remain, these advances create some optimism about the use of small molecules to inhibit RAB10 and impact AD pathology.

Antibodies function in extra- and intracellular immunity to recognize foreign or abnormal agents and target them for destruction with very high specificity. The production of monoclonal antibodies (mAb) has resulted in their use for the treatment of a wide range of human diseases [55]. There are currently >60 approved mAbs for human therapy and >50 in late-stage clinical trials [61].

Rnase H-dependent antisense oligonucleotides technology is a popular method for knockdown in cell culture. It offers specific and efficient knockdown and is a powerful tool for functional studies of genes with unknown function [62]. Antisense technology has challenges such as site specificity, toxicity at high concentrations, and the difficulty of targeting specific cell-types. However, it is a mature technology and antisense oligonucleotides offer a means to manipulate specific steps in mRNA processing, for example splicing [53]. As discussed previously, *in vitro* reduction of *Rab10/RAB10* expression using shRNA and RNAi has been

successful [36]. Expansion of antisense oligodeoxynucleotide from *in vitro* to *in vivo* represents a promising therapeutic avenue given recent successes with Spinal muscular atrophy and Huntington's disease [63, 64].

As the field of AD genetics has progressed, it has become increasingly clear that critical work needs to be done to understand not only the variants that increase disease risk, but also the variants that confer resilience to disease. Not only will such important work shed increasing light on the cellular and molecular mechanisms for how the brain combats AD, but will also assist researchers in developing more effective novel therapeutics to treat AD as well as other devastating forms of dementia and neurodegeneration.

**Chapter 4: Phospholipase D3 contributes to  
Alzheimer's disease risk via disruption of A $\beta$   
clearance and microglia response to amyloid  
plaques**

## 4.1 Abstract

Alzheimer's disease (AD) is characterized by the accumulation of amyloid- $\beta$  (A $\beta$ ) plaques and neurofibrillary tangles in the brain. AD is also the result of complex genetic architecture that can be leveraged to understand pathways central to disease processes. We have previously identified coding variants in the *phospholipase D3* (*PLD3*) gene that double the late-onset AD risk. However, the mechanism by which *PLD3* impacts AD risk is unknown. One AD risk variant, *PLD3* p.A442A, disrupts a splicing enhancer-binding site and reduces *PLD3* splicing in human brains. Using differentiated induced pluripotent stem cells from a *PLD3* p.A442A carrier and CRISPR-reverted, isogenic control, we show that *PLD3* p.A442A cortical neurons exhibit a *PLD3* splicing defect and a significant increase in A $\beta$ 42 and A $\beta$ 40, both of which are corrected upon reversion of the risk allele in isogenic control neurons. Thus, *PLD3* p.A442A is sufficient to alter *PLD3* splicing and A $\beta$  metabolism. While the normal function of *PLD3* is poorly understood, *PLD3* is highly expressed in neurons and brain regions most susceptible to amyloid pathology. *PLD3* expression is significantly lower in AD brains than controls, suggesting that *PLD3* may play a role in sporadic AD. Thus, we sought to determine whether *PLD3* contributes to A $\beta$  accumulation in AD. In a mouse model of amyloid accumulation, loss of *Pld3* increases interstitial fluid (ISF) A $\beta$  and reduces A $\beta$  turnover. AAV-mediated overexpression of *PLD3* in the hippocampus decreased ISF A $\beta$  levels and accelerated A $\beta$  turnover. To determine whether *PLD3*-mediated reduction of ISF A $\beta$  impacts amyloid accumulation, we measured amyloid plaque abundance and size after significant A $\beta$  deposition. We found that in the absence of *Pld3*, amyloid plaques were less compact and more diffuse. Additionally, we observed reduced recruitment of microglia to amyloid plaques in the absence of

*Pld3*. PLD3 may impact amyloid accumulation and AD risk through disrupted microglia function as *PLD3* is enriched in disease associated microglia in human brains. Together, our findings demonstrate that PLD3 regulates A $\beta$  clearance through cell-autonomous and non-cell-autonomous pathways in a manner that likely contributes to AD risk.

## 4.2 Introduction

Alzheimer's disease (AD) is pathologically defined by neuronal loss and the accumulation of amyloid- $\beta$  (A $\beta$ ) plaques and neurofibrillary tangles in the brain. Genetic, biochemical, and neuropathologic data suggest that A $\beta$  aggregation is central to initiating AD pathogenesis [1]. Rare mutations in *APP*, *PSEN1*, and *PSEN2* cause dominantly inherited AD. Late-onset AD (LOAD) also has a strong genetic component [2]. Identifying novel loci that affect LOAD risk is critical to our understanding of the underlying etiology of AD and novel therapeutic pathways.

The genetic architecture that underlies LOAD is complex [2]. Large-scale genomic studies have led to the identification of novel genes and risk loci that contribute to AD [2, 3]. Whole exome sequencing of densely affected LOAD families has revealed a rare genetic variant within *PLD3* (p.V232M) that perfectly segregated with disease in two independent families and doubled AD risk in seven independent case-control series (4,998 AD cases/6,356 controls; OR=2.10, p=2.93 $\times$ 10 $^{-5}$ ) [4]. Gene-based analyses indicated that multiple variants in *PLD3* increase AD risk in European (EA) and African American (AA) populations (e.g.: p.M6R, p.V232M, p.A442A; EA: OR=2.75, p=1.44 $\times$ 10 $^{-11}$ ; AA: OR=5.48, p=1.40 $\times$ 10 $^{-3}$ ) [4].

*PLD3* is a non-classical member of the phospholipase D (PLD) family of enzymes, with no known function [5-7]. *PLD3* is expressed in pyramidal neurons within the brain, and in AD brains, *PLD3* co-localizes with amyloid plaques [8, 9]. Common variants in *PLD3* are associated with CSF A $\beta$  levels, an AD biomarker [10]. *In vitro*, *PLD3* expression is correlated with extracellular A $\beta$  levels: *Pld3* silencing is associated with increased A $\beta$  levels, and *PLD3*

overexpression is associated with reduced A $\beta$  levels [4]. Thus, PLD3 may play a broader role in LOAD.

Here, we sought to define the contribution of *PLD3* risk variants to AD-related phenotypes in human stem cell models and the role of PLD3 in amyloid pathology in mouse models. We found that a *PLD3* risk variant is sufficient to increase A $\beta$  levels in stem cell-derived neurons. In animal models of amyloid accumulation, *Pld3* silencing reduces A $\beta$  turnover and alters the composition of amyloid plaques. In the absence of *Pld3*, microglia recruitment to plaques is attenuated. Together, this study suggests that PLD3 contributes AD pathogenesis via A $\beta$  clearance through cell-autonomous and non-cell-autonomous pathways.

### **4.3 Materials and Methods**

#### *Patient Consent*

Skin biopsies were collected following written informed consent from the donor. The Washington University School of Medicine Institutional Review Board and Ethics Committee approved the informed consent (IRB 201104178, 201306108). The consent allows for the use of tissue by all parties, commercial and academic, for research but not for human therapy.

#### *Dermal Fibroblast Isolation*

Dermal fibroblasts were isolated from skin biopsies obtained from the Knight Alzheimer Disease Research Center (ADRC) research participants. Briefly, skin biopsies were collected by surgical punch and stored in Fibroblast Growth Media (Lonza). To isolate dermal fibroblasts from a skin biopsy, the biopsies were rinsed with PBS and cut lengthwise with dissecting scissors. The resulting tissue sections were then plated into a dry 24-well tissue culture-treated

plate (approximately 6-12 sections). After removing excess PBS from the wells, 300ul of fibroblast growth media (Lonza) was carefully added and tissue was incubated at 37°C and 5% CO<sub>2</sub>. After 24 hours, tissue was supplemented with 1mL fibroblast growth media and media changes were repeated every 3-4 days. Fibroblast cells migrated from the tissue within two weeks of culture. Dermal fibroblasts were maintained in fibroblast growth media (Lonza) supplemented with penicillin/streptomycin.

### *iPSC Generation, Characterization, and Maintenance*

Human fibroblasts (F13504) were transduced with non-integrating Sendai virus carrying the four factors required for reprogramming: OCT3/4, SOX2, KLF4, and cMYC [11, 12]. Cells showing morphological evidence of reprogramming were selected by manual dissection.

Human iPSCs were cultured using feeder-free conditions (Matrigel, BD Biosciences, Franklin Lakes, NJ, USA). Human iPSCs were thawed (1-2 x 10<sup>6</sup> cells/mL), diluted in DMEM/F12, and centrifuged at 750 rpm for 3 minutes. The resulting iPSC pellet was then diluted in mTeSR1 supplemented with Rock inhibitor (Y-27632; 10µM final). iPSC were subsequently cultured in 37°C, 5% CO<sub>2</sub> with daily medium changes (mTesR1, STEMCELL Technologies, Vancouver, BC, CA).

All iPSC lines were characterized using standard methods [11]. Each line was analyzed for pluripotency markers (OCT4A, SOX2, SSEA4, TRA1-80) by immunocytochemistry (ICC) (Invitrogen A24881) and quantitative PCR (qPCR); for chromosomal abnormalities by karyotyping; and for *PLD3* variant status by Sanger sequencing (Supplemental Figure 4.1).

### *Genome editing*

We used CRISPR/Cas9 to generate isogenic control lines for the *PLD3* p.A442A iPSC as previously described [13]. The p3s-Cas9HC Cas9 expression plasmid (Addgene 43945) and CRISPR reagents (Addgene plasmid 43860) were used [14]. Guide RNAs were designed to overlap with the allele to be modified and have at least 3bp of mismatch to any other gene in the human genome. The activity of the guide was validated using a mismatch detection assay to determine non-homologous end-joining efficiency in K562 cells. A correctly edited clone and an unmodified clone were identified, expanded and characterized as described above for karyotyping and pluripotency markers. Sanger sequencing was performed for the on-target and predicted off-target sites.

### *Cortical neuron differentiation*

iPSCs were differentiated into neuronal cells using a two-step approach as previously described [13]. iPSCs were plated at a density of 65,000 cells per well in neural induction media (STEMCELL Technologies) in a 96-well v-bottom plate to form highly uniform neural aggregates and, after five days, transferred onto culture plates. The resulting neural rosettes were then isolated by enzymatic selection (Neural Rosette Selection Reagent; STEMCELL Technologies) and cultured as neural progenitor cells (NPCs). NPCs were differentiated in planar culture in neuronal maturation medium (neurobasal medium supplemented with B27, GDNF, BDNF, cAMP). Neurons typically arise within one week after plating, identified using immunocytochemistry for β-tubulin III (Tuj1). The cells continued to mature and were analyzed at six weeks.

### *Immunocytochemistry*

IPSC-derived neurons were grown on PLO/laminin-coated 8-well chamber slides (Millipore). Culture media was aspirated, and cells were then washed and fixed with 4% paraformaldehyde (Sigma). After several washes, cells were permeabilized with 0.1% Triton X-100 in PBS. Cells were then blocked in 0.1% bovine serum albumin (BSA; Sigma) and treated with primary (Tuj1) and secondary antibodies diluted in 0.1% BSA. Immunostained cells were then imaged (Nikon Eclipse 80i fluorescent microscope).

### *Transcriptomics and Digital Deconvolution*

RNA was extracted from iPSC-derived neurons from *PLD3* p.A442A vs. the isogenic controls using Tissue Lyser LT and RNeasy Mini Kit (Qiagen, Hilden, Germany). RNA-seq paired-end reads with read lengths of 2 × 150 bp were generated using Illumina HiSeq 4000 with a mean coverage of 80 million reads per sample. FastQC was applied to perform quality control and aligned to human GRCh37 primary assembly using Star (ver 2.5.2b). We applied Salmon transcript expression quantification (ver 0.7.2) to infer the gene expression. To estimate the relative proportion of major brain cell types in the dish, digital deconvolution was performed as previously described using a reference marker panel [15].

### *PLD3 Splicing Assay*

RNA was extracted from cell lysates with an Rneasy kit (Qiagen) according to the manufacturer's protocol. Extracted RNA (10ug) was converted to cDNA by PCR using the High-Capacity cDNA Reverse Transcriptase kit (ABI). SYBR-green primers were designed using Primer Express software, Version 3 (ABI). Real-time PCR assays were used to quantify *PLD3* exon 7 (forward primer: GCAGCTCCATCCCATCAACT; reverse: CTTGGTTGTAGCGGGTGTCA), exon 8 (forward primer: CTCAACGTGGTGGACAATGC;

reverse: AGTGGGCAGGTAGTCATGACA), exon 9 (forward primer: ACGAGCGTGGCGTCAAG; reverse: CATGGATGGCTCCGAGTGT), exon 10 (forward primer: GGTCCCCGCGGATGA; reverse: GGTTGACACGGGCATATGG) and exon 11 (forward primer: GCTGCTGGTGACGCAGAAT; reverse: AGTCCCAGTCCCTCAGGAAAA). Each qPCR analysis included technical replicates and biological triplicates. Real-time data were analyzed using the comparative Ct method. Only samples with a standard error of <15% were analyzed. The Ct values for exon 11 were normalized with the Ct value for exons 7-10. The relative exon 11 levels for the iPSC-derived neurons from *PLD3* p.A442A vs. the isogenic control were compared using a Tukey's t-test.

### *A $\beta$ Measurements*

Conditioned medium was collected from neurons after six weeks in culture and centrifuged at 3,000xg at 4°C for 10 minutes to remove cell debris. The levels of A $\beta$ 42 and A $\beta$ 40 were measured in cell culture media by sandwich ELISA as described by the manufacturer (Life Technologies). To account for variability in transfection efficiency between experiments, ELISA values were obtained (pg/mL) and corrected for total intracellular protein (ug/mL). Statistical difference was measured using an unpaired Student's t-test.

### *PLD3 expression in AD and neuropathology free human brains*

Laser microdissected neurons from AD and control brains were previously reported and deposited as GSE5281 [38]. Brain samples were analyzed from 47 individuals of European descent clinically and neuropathologically confirmed AD cases or controls. The 33 AD samples were 54.5% female with a mean age of 79.9 years (range 73–86.8) and an average postmortem interval (PMI) of 2.5 hours. The 14 control brains were 28.6% female with a mean age of 79.8

years (range 70.1–88.9). Samples were obtained from the entorhinal cortex, hippocampus, medial temporal gyrus, posterior cingulate, superior frontal gyrus, and primary visual cortex. RNA expression was measured using an Affymetrix GeneChip for gene expression. The log-transformed expression values were analyzed with brain region, age, and sex as covariates to analyze RNA expression.

Gene expression was analyzed in a second, independent, publicly available dataset of the temporal cortex of 76 control and 80 AD brains (syn6090813). Differential gene expression comparing controls v. AD was performed using a “Simple Model”, multi-variable linear regression analyses were conducted in R, using normalized gene expression measures including sex, age-at-death, RNA integrity number, brain tissue source, and flowcell as covariates [16]. Statistical difference was measured using an unpaired Student’s t-test.

### *Single nuclei RNAseq in human brains*

Human parietal cortices were processed to isolate nuclei, and the nuclei were then sequenced using the 10X Chromium single cell Reagent Kit v3, with 10,000 cells per sample and 50,000 reads per cell for each of the 74 samples as previously described [17, 18]. The CellRanger (v3.0.2 10Xgenomics) software was used to align the sequences and quantify gene expression. We used the GRCh38 (3.0.0) reference to prepare a pre-mRNA reference. Filtering and QC were done using the Seurat package (3.0.1) on each subject individually. After the Uniform Manifold Approximation and Projection (UMAP) analysis was performed with the top 14 PCs, we then used Seurat *FindNeighbors* and *FindClusters* functions to identify unique cell states or subclusters. Samples included in the subsequent analyses are summarized in Supplemental Table 4.1. To identify associations between cell-type transcriptional state and

disease status or genetic strata (control, sporadic AD (sAD), TREM2), we applied linear regression models to test the cell state compositions of each subject. The proportions were normalized using a cube root transformation and were corrected by sex and age of death. Differentially expressed genes among the individual cell states were identified using a linear mixed model that corrected for sex and subject. To determine if there was unique functionality or potentially altered expression levels associated with disease/genetic carriers in the alternative cell states, we employed linear mixed model that predicted the expression level of each gene, modeled as zero-inflated negative binomial distributions and corrected for sex and age of death. Donors were modeled as random variables as previously described [17]. Data can be publicly accessed at <http://ngi.pub/SNARE>.

### *Mouse Models*

Animal care and surgical procedures were approved by the Animal Studies Committee of Washington University School of Medicine in accordance with guidelines of the United States National Institutes of Health. APPswe/PS1 $\Delta$ E9 transgenic mice (APP/PS1; The Jackson Laboratory; 034829) [19] of both sexes were used in this study. APP/PS1 mice were maintained on a C57Bl6;C3B6 mixed background.

*Pld3-KO* mice were generated using CRISPR/Cas9 technology. gRNAs were designed to target an early conserved exon (mPld3.g19; TGCTGTGAGCACCGCAAGGNGG). Guide activity was assessed in mouse neuroblastoma cells (N2A) using a T7E1 mismatch detection assay as previously described [13]. RNA was injected into the pronuclei of fertilized, viable murine oocytes isolated from a set of C57Bl/6xCBA (hybrid) female mice. Founders were identified using mPLD3 screening primers SM406.Cel.F 5' CATGGGCACTGTATCCCATCT

3' and SM406.Cel.R 5' AGGACACAAAAACGTCACCCCT 3', which generated a parental band (575bp) and fragments (307 and 268bp). Subsequent generations were backcrossed to C57Bl/6;C3B6 (Supplemental Figure 4.2).

APP/PS1 mice were crossed with the *Pld3*-KO mice to generate APP/PS1x*Pld3*<sup>+/−</sup>. APP/PS1x*Pld3*<sup>+/−</sup> were crossed to obtain APP/PS1x*Pld3*-KO (APP/PS1x*Pld3*<sup>−/−</sup>) mice and APP/PS1x*Pld3*-WT (APP/PS1x*Pld3*<sup>+/+</sup>) littermates. Animals of both sexes were used in the study.

### *Intracranial AAV-mediated expression of PLD3 and shPLD3*

Adeno-associated virus (AAV8) particles were generated that express AAV-CMV-hPLD3-WT-GFP, AAV-CMV-GFP (control), AAV-U6-shPLD3-GFP, and AAV-U6-shScrambled-GFP (control). Viral particles were injected into the hippocampus of APP/PS1 mice of both sexes to produce widespread transduction in hippocampal neurons as previously described [20, 21]. Two uL of AAV particles ( $1.5 \times 10^{12}$  vg/ml) were stereotactically injected bilaterally hippocampi (2μl over 10 minutes) in 3-month-old APP/PS1 transgenic mice (prior to plaque appearance) [22, 23]. Virus is detectable at least 4-5 months post-injection [21, 24].

### *In Vivo Microdialysis*

Prior to plaque accumulation (5 months of age) and two months post AAV8-injection, hippocampal ISF Aβ levels were quantified using microdialysis in APP/PS1 mice as previously described [25, 26]. The use of a 38-kDa MWCO semi-permeable membrane allows for molecules smaller than this cut-off to diffuse into the probe. The probe was flushed with perfusion buffer at a constant rate (1.0μl/minute) and collected into a refrigerated fraction

collector, and then assayed by sandwich ELISA ( $A\beta_{x-40}$ ). A mouse monoclonal anti- $A\beta_{40}$  capture antibody (mHJ2) made in-house was used in conjunction with a biotinylated central domain detection antibody (mHJ5.1) and streptavidin-poly-HRP-40 (Fitzgerald Industries, Acton, MA)[27]. During microdialysis, mice were housed in cages that permit free movement and ad-libitum food/water, while ISF  $A\beta$  was sampled. Baseline levels of ISF  $A\beta$  were sampled every 60 minutes between hours 5-12 (after the microdialysis probe insertion) and averaged to determine the baseline ISF  $A\beta$  levels in each mouse. At hour 12, mice were administered the  $\gamma$ -secretase inhibitor Compound E (20mg/kg), intraperitoneally, which enabled us to determine the elimination half-life of ISF  $A\beta$  [28].  $A\beta$  half-life was calculated using first-order kinetics. Microdialysis was performed with sham and littermate controls. Statistical difference was measured using an unpaired Student's t-test.

To evaluate the impact of *Pld3* on  $A\beta$  kinetics, APP/PS1x*Pld3*-WT and APP/PS1x*Pld3*-KO mice were implanted at one-month post-injection with a microdialysis probe with a 38-kDa MWCO probe, and ISF was collected as described above. After 12 hours,  $\gamma$ -secretase inhibitor LY411575 (3mg/kg in 50:50PBS:PEG400) was administered intraperitoneally to define the elimination half-life of ISF  $A\beta$ .  $A\beta$  half-life was calculated as described above. Microdialysis was performed with sham and littermate controls. Statistical difference was measured using an unpaired Student's t-test.

### *Brain Tissue Preparation*

APP/PS1x*Pld3*-WT and APP/PS1x*Pld3*-KO mice were anesthetized with sodium pentobarbital and perfused with 0.3% heparin in PBS at nine months of age. Brains were dissected and cut into two hemispheres. The right hemisphere was snap-frozen on dry ice and

stored at 80°C for biochemical analyses. The left hemisphere was fixed in 4% paraformaldehyde for 24 hours, followed by 30% sucrose in PBS at 4°C. Coronal sections (50 µm) were cut on a freezing-sliding microtome. Collected slices were stored in cryoprotectant solution (0.2 M phosphate-buffered saline, 30% sucrose, and 30% ethylene glycol) at -20°C.

### *Immunohistochemistry*

APP/PS1x*Pld3*-WT and APP/PS1x*Pld3*-KO brains were cut into 50µm sections from the rostral anterior commissure to the caudal hippocampus. Brains sections (n=20 mice per group) were incubated in 0.3% H<sub>2</sub>O<sub>2</sub> in Tris-buffered saline (TBS) for 10 minutes and blocked in 3% milk in TBS-X for 30 minutes. Tissue was incubated in HJ3.4B antibody (anti-Aβ-1-13; 2.4 µg/ml; a generous gift from the Holtzman lab) overnight [29]. Sections are then incubated in Vectastain ABC elite solution in TBS (1:400) for 1 hour before incubating in 3,3'-Diaminobenzidine (DAB) solution. Sections were then mounted onto slides with Cytoseal (Thermo Scientific 8312-4). A Nanozoomer Digital Scanner (Hamamatsu Photonics) was used to create high-resolution digital images for the HJ3.4-stained brain slices. Total plaque coverage, total plaque count, and average plaque size were analyzed using NIH ImageJ software. Total plaque coverage was expressed as a percentage of the total area for each slice and averaged across the three slices per animal. Plaque count was expressed as the plaque count per nm<sup>2</sup> averaged across the three slices per animal. Plaque size was expressed in µm<sup>2</sup> averaged across all three slices for each mouse. Both the hippocampus and cortex were analyzed separately for each slice. Statistical difference for plaque size, percentage of total area, and plaque count per square millimeter was measured using an unpaired Student's t-test.

### *X-34 Plaque Staining*

To evaluate X-34 positive plaque burden, frozen coronal brain sections (50 µm) were mounted on Superfrost Plus slides, permeabilized with 0.25% Triton X-100 in PBS for 30 minutes and stained with X-34 (0.01mM; Sigma SML1954) dissolved in 40% ethanol in PBS, pH 10 for 20 min. The tissue was then washed with 40% ethanol in PBS and mounted with Fluoromount G mounting medium. Slides were imaged using Cytaion7 (BioTek) and quantified using NIH ImageJ software. A Cytaion7 cell imaging multi-modal imager was used to create high-resolution images of the X-34 scanned brain sections. Total plaque coverage, total plaque count, and average plaque size were analyzed using NIH ImageJ software. Total plaque coverage was expressed as a percentage of the total area for each section and averaged across three sections per animal. Plaque count was expressed as the plaque count per square millimeter averaged across the three sections per animal. Plaque size was expressed in square microns averaged across all three sections for each mouse. Both the hippocampus and cortex were analyzed separately for each section. Statistical difference for plaque size, percentage of total area, and plaque count per square millimeter was measured using an unpaired Student's t-test.

### *Immunofluorescence*

Coronal brain sections (50µm) were permeabilized in 0.25% Triton X-100 for 30 min at room temperature. Slices were then stained with X-34 (0.001 mM; Sigma SML1954) dissolved in 40% ethanol in PBS for 20 min and blocked in 3% BSA/3% Normal Donkey serum in 0.1% Triton X-100 in PBS. X-34-stained samples were immunostained with antibodies HJ3.4 (2.4ug/mL;  $\alpha$ -A $\beta$ 1-13) or Iba1 (Abcam ab5076) and CD68 (BioRad MCA1957) at 4°C overnight. Three slices per animal were stained. Secondary antibodies of Alexa Fluor 488-conjugated donkey anti-rat IgG, Alexa Fluor 647-conjugated donkey anti-goat, and Alexa Fluor 647 donkey anti-mouse (Invitrogen). Slides were mounted with Fluoromount G mounting media.

High resolution 40x images were obtained using the Zeiss LSM 880 Confocal microscope with Airyscan. Z-stacks were analyzed using NIH ImageJ software, where max projection images (those with the highest signal intensity) were selected for each fluorescent channel. The Iba1 and CD68 signals were quantified within 15 $\mu$ m of the X-34-positive plaques. Iba1 and CD68 colocalization was also quantified. An outlier analysis was run using the ROUT method with a Q-value of 1%. Three outliers were removed from the APP/PS1x*Pld3*-KO mice in the Iba1 analysis. Statistical difference was measured using an unpaired Student's t-test.

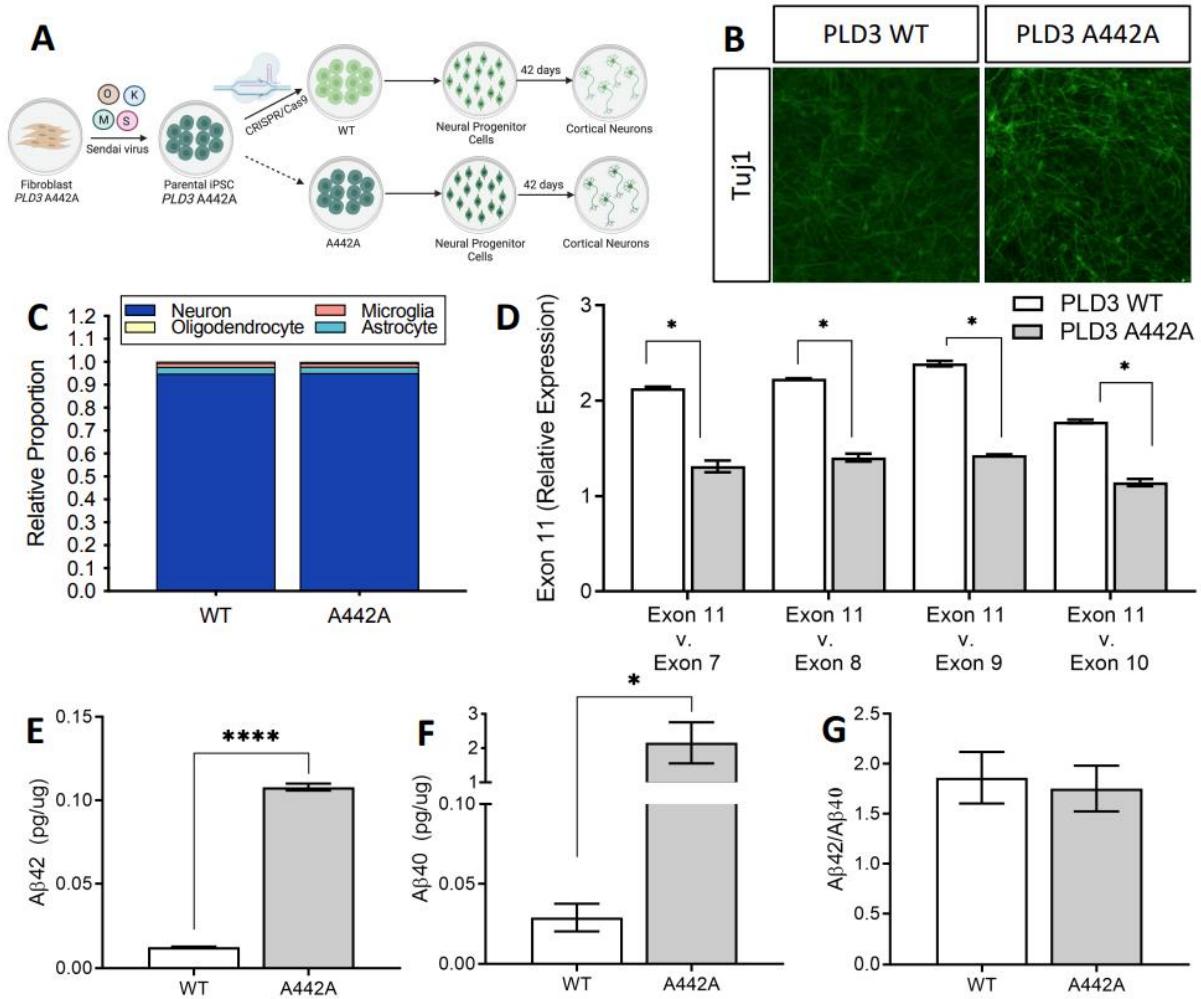

To quantify HJ3.4 and X-34 colocalization, Z-stacks were analyzed using NIH ImageJ software, where max projection images were selected for each fluorescent channel. Plaque composition was quantified by measuring the percentage of HJ3.4 staining within X-34-positive areas. Nonfibrillar plaque area was normalized to the total X-34 area. A ROUT outlier analysis with a Q-value of 1% was run for each of these quantifications. No outliers were removed from the analysis of percent area. Four outliers were excluded in the APP/PS1x*Pld3*-WT mice, and three outliers were excluded in the APP/PS1x*Pld3*-KO mice in the nonfibrillar plaque area analysis. Statistical difference was measured using an unpaired Student's t-test.

#### **4.4 Results**

*AD risk variant PLD3 p.A442A is sufficient to alter PLD3 splicing and A $\beta$  levels*

Three highly conserved, rare variants in *PLD3* increase AD risk: p.M6R, p.V232M, and p.A442A [4]. *PLD3* p.A442A (G>A) was associated with increased AD risk in four independent case-control datasets ( $p=3.78\times 10^{-7}$ ; OR=2.12) [4]. *PLD3* p.A442A was predicted to modify a splicing enhancer-binding site, SRSF1, *in silico* [4]. In the brains of *PLD3* p.A442A carriers,

total *PLD3* and exon 11-containing transcript expression were reduced compared to controls [4]. However, these association studies did not allow us to attribute the causality of the risk variant to the phenotype.

**Figure 4.1: iPSC-neurons expressing *PLD3* p.A442A phenocopy splicing defects observed in human brains A.**

Fibroblasts from a *PLD3* p.A442A variant carrier were reprogrammed into induced pluripotent stem cells (iPSCs). CRISPR-Cas9 technology was used to generate an isogenic control line. iPSCs were then differentiated into cortical neurons (see Methods). Downstream assays were performed after 42 days in culture. B. iPSC-derived neurons stained with Tuj1 illustrate a similar capacity of p.A442A and isogenic controls (*PLD3* WT) to form neurons. C.

Digital deconvolution of iPSC-derived neurons from transcriptomic data illustrates a similar enrichment of neurons in *PLD3* p.A442A and isogenic controls (*PLD3* WT). D. Expression of *PLD3* exon 11 compared to *PLD3* exons 7, 8, 9, and 10. E-G. Sandwich ELISA of media from iPSC-derived neurons (pg/mL) and corrected for total protein measured by BCA (pg/μg). Aβ42 (E), Aβ40 (F), Aβ42/40 (G). Graphs represent mean ± SEM. \* $<0.05$ , \*\*\* $<0.00005$ . Analyzed by two-tailed Student's *t* test.

Here, we coupled genome-editing with stem cell models to determine whether *PLD3* p.A442A is sufficient to alter *PLD3* splicing and phenocopy AD-related phenotypes. Primary dermal fibroblasts were obtained from a patient carrying a single copy of the *PLD3* p.A442A variant. Fibroblasts were de-differentiated into induced pluripotent stem cells using non-integrating Sendai virus. The resulting iPSC were characterized for pluripotency markers, the presence of the *PLD3* p.A442A variant, and chromosomal integrity (Supplemental Figure 4.1). To determine the causality of *PLD3* p.A442A on AD-related phenotypes, we used CRISPR/Cas9 to correct the A allele to G (wild-type) (Figure 4.1A) [13]. *PLD3* p.A442A and isogenic controls (*PLD3* WT) were then differentiated into cortical neurons using a growth factor-mediated approach as previously described (Figure 4.1A) [13], where they illustrated a similar capacity to form Tuj1-positive neurons (Figure 4.1B). To further verify the similarity between the cells in their capacity to form neurons, we estimated the relative proportion of neurons in the cultures using bulk transcriptomics and deconvolution methods that include all the major brain cell types [15]. We found that differentiated cultures from *PLD3* p.A442A and isogenic controls exhibited a similar enrichment of neurons (~95%; Figure 4.1C). These findings are consistent with a variant that impacts a late-onset disease, where we would not predict a significant developmental defect.

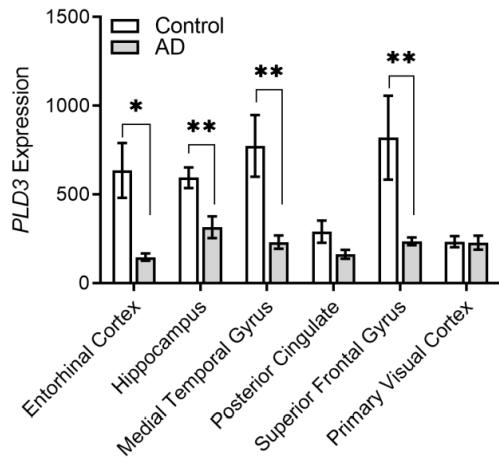

Having demonstrated that *PLD3* p.A442A and isogenic controls share a similar capacity to form neurons, we next asked whether the *PLD3* p.A442A variant was sufficient to alter *PLD3*

splicing in a manner consistent with our prior observations in human brains from *PLD3* p.A442A carriers [4]. RNA isolated from neurons expressing *PLD3* p.A442A and isogenic controls was converted to cDNA, and *PLD3* exons 7, 8, 9, 10, and 11 were amplified and quantified. We found that *PLD3* exons are significantly reduced in the *PLD3* p.A442A neurons, which is restored upon correction of the variant allele to WT (Figure 4.1D). To determine whether *PLD3* p.A442A neurons exhibit changes in A $\beta$ , which would be consistent with a variant that impacts amyloid plaque deposition, we measured extracellular A $\beta$  by sandwich ELISA in the media of *PLD3* p.A442A and isogenic control neurons. After correcting for total protein, we observed a significant increase in A $\beta$ 42 and A $\beta$ 40 in media from neurons expressing *PLD3* p.A442A (Figure 4.1E and 4.1F) without changing the A $\beta$ 42/40 ratio (Figure 4.1G) when compared to isogenic controls. Together, these findings illustrate that in nearly identical, isogenic neurons, the presence of the *PLD3* p.A442A is sufficient to alter *PLD3* transcripts and extracellular A $\beta$  levels.

### *PLD3 expression is altered in LOAD brains*

Having demonstrated that the AD risk variant in *PLD3* (*PLD3* p.A442A) was sufficient to alter *PLD3* transcripts and A $\beta$  levels, we sought to determine whether *PLD3* is altered in LOAD. We examined *PLD3* expression in laser-captured microdissected neurons across multiple brain regions from AD cases and neuropathology-free controls. *PLD3* expression was significantly lower in AD brains compared with control brains in the entorhinal cortex, hippocampus, medial temporal gyrus, and superior frontal gyrus (Figure 4.2), regions that exhibit amyloid and tau pathology. Interestingly, *PLD3* expression was unaltered in the primary visual cortex, which is largely spared of AD pathology (Figure 4.2) [30]. *PLD3* expression was also significantly reduced in an independent cohort of temporal cortices isolated from AD and control

brains ( $\beta=-0.36$ ;  $p=3.23\times10^{-4}$ ) [31]. These findings are consistent with prior reports of reduced *PLD3* expression in LOAD brains [4].

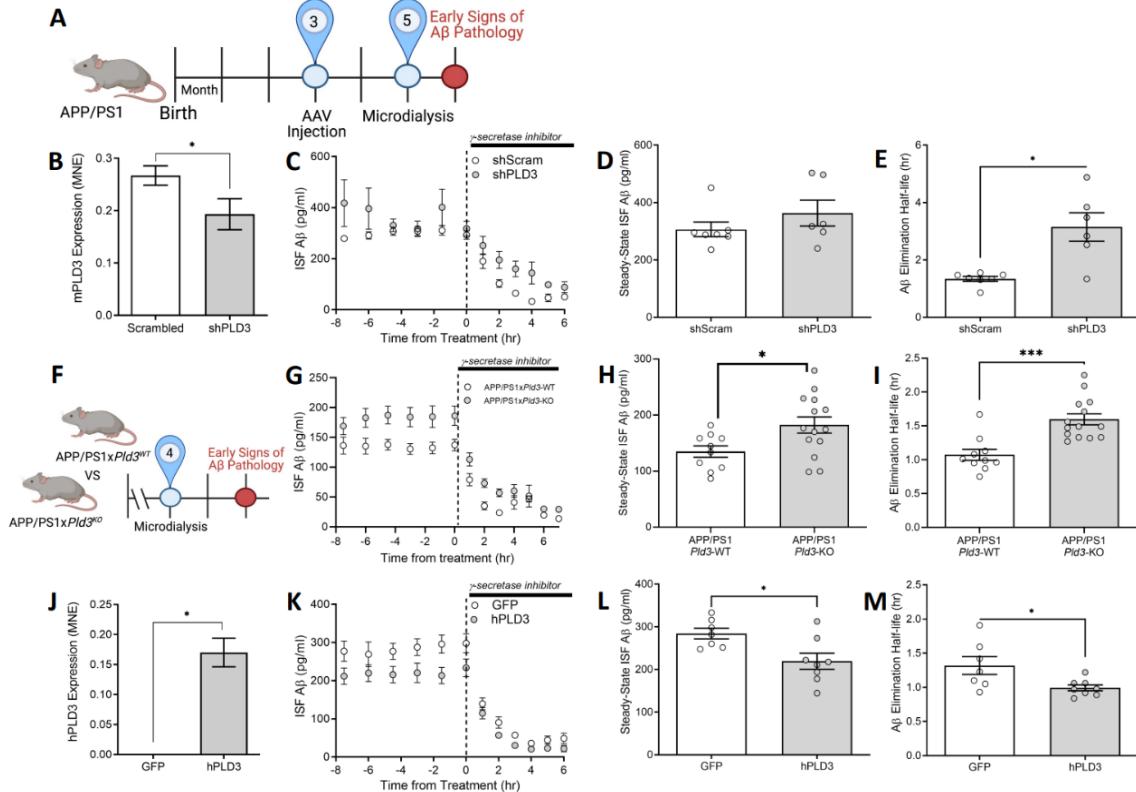

**Figure 4.2: *PLD3* expression is significantly reduced in brain regions vulnerable to AD pathology.** Laser capture of microdissected neurons from the brains of neuropathology confirmed control and AD brains [32]. Quantification of *PLD3* expression in laser microdissected neurons isolated from AD and control brains (AU). The graph represents mean  $\pm$  SEM. \* $p<0.05$ . Analyzed by two-tailed Student's *t* test.

### *Pld3 regulates A $\beta$ in APP/PS1 mice*

*PLD3* expression is reduced in brains from *PLD3* p.A442A carriers and in LOAD brains (Figure 4.2) [4], and overexpression or silencing of *PLD3* in mouse neuroblastoma cells leads to inverse changes in A $\beta$  levels [4]. Thus, we sought to determine whether modulating *PLD3* expression is sufficient to alter A $\beta$  *in vivo*. In mice, A $\beta$  is primarily generated in neurons and released into the ISF, where it can be cleared by extracellular proteolysis, transported into CSF or across the blood-brain barrier, or by cellular uptake and degradation. The steady-state level of ISF A $\beta$ , thus, reflects these production and degradation/clearance mechanisms. We hypothesized that reducing endogenous *Pld3* expression, as observed in human AD brains, would elevate ISF

$\text{A}\beta$  levels. To address this hypothesis, 3-month-old APP/PS1 mice were injected with AAV8 particles containing shPld3 or shScrambled (control) and evaluated at five months of age by *in vivo* microdialysis (Figure 4.3A). At five months of age, shPld3 was sufficient to significantly reduce endogenous *Pld3* transcript level in the hippocampus compared with scrambled controls by 28% (Figure 4.3B). This modest reduction of *Pld3* did not alter steady-state ISF  $\text{A}\beta$  levels (Figure 4.3C and 4.3D;  $p=0.27$ ). Next, to test the impact of *Pld3* silencing on the  $\text{A}\beta$  elimination rate (half-life),  $\text{A}\beta$  levels were monitored after treatment with a  $\gamma$ -secretase inhibitor (Figure 4.3C). The secretase inhibitor rapidly blocks  $\text{A}\beta$  generation within minutes, then ISF is sampled hourly to calculate the rate of elimination of existing  $\text{A}\beta$ . Silencing of *Pld3* resulted in a 135% increase in  $\text{A}\beta$  elimination half-life (Figure 4.3C and 4.3E;  $p=0.0025$ ). Thus, PLD3 is likely involved in  $\text{A}\beta$  clearance. The striking impact of a modest *Pld3* decrease in  $\text{A}\beta$  levels in the APP/PS1 mice led us to investigate the impact of a global knockout of *Pld3* on  $\text{A}\beta$  (Figure 4.3F). Global *Pld3* knockout mice were generated using CRISPR/Cas9. A guideRNA targeting an early, highly conserved exon was validated *in vitro* and injected into murine oocytes (see Methods; Supplemental Figure 4.2). Founders were established and backcrossed to C57Bl/6;C3B6 prior to breeding with APP/PS1 mice (Supplemental Figure 4.3C). Consistent with prior reports, *Pld3* KO mice were viable and did not exhibit gross defects [9, 33]. *Pld3*-deficient APP/PS1 mice exhibited a 35% increase in steady-state ISF  $\text{A}\beta$  at four months of age (Figure 4.3G-4.3I). In agreement with the AAV-mediated knockdown, *Pld3*-deficient APP/PS1 mice exhibited a 49% increase in  $\text{A}\beta$  elimination half-life following the administration of a  $\gamma$ -secretase inhibitor (Figure 4.3G and 4.3I). Thus, *Pld3* reduction in the brain is sufficient to reduce the turnover of ISF  $\text{A}\beta$ .

*In vitro* overexpression of *PLD3* was sufficient to reduce extracellular A $\beta$  [4]. Thus, we asked whether overexpression of *hPLD3* in APP/PS1 mice could rescue the ISF A $\beta$  phenotype (Figure 4.3A). The hippocampus of APP/PS1 mice was bilaterally injected with AAV8 particles containing hPLD3 or GFP (control) at three months of age, and two months later, ISF A $\beta$  was

**Figure 4.3: Bi-directional expression of *Pld3* alters A $\beta$  turnover *in vivo*.** A-E. The impact of *Pld3* silencing on ISF A $\beta$ . A. measured by microdialysis (Figure 4.3A). Overexpression of *hPLD3* significantly reduced steady-state levels of ISF A $\beta$  and A $\beta$  elimination half-life by approximately 25% (Figure 4.3J-M). Taken together, our findings illustrate that PLD3 expression regulates A $\beta$  turnover in APP/PS1 mice.

### *Pld3-deficiency alters plaque composition*

Impairment in protein clearance has been implicated in amyloid plaque accumulation and AD pathogenesis [34, 35]. A $\beta$  aggregation in the extracellular space (ISF) into soluble oligomers or insoluble amyloid plaques is a critical driver of AD pathogenesis, and conversion of monomeric A $\beta$  into these aggregates is facilitated at higher concentrations [36]. Thus, we sought to determine whether increased ISF A $\beta$  in four months old APP/PS1x*Pld3*-KO mice could impact amyloid plaque pathology in older animals (Figure 4.4A). To assess plaque pathology, APP/PS1x*Pld3*-KO mice were sacrificed at nine months of age, and brain sections were co-stained with HJ3.4 (total A $\beta$ ) and X-34 ( $\beta$ -sheet rich dense cores; Figure 4.4B). Plaque composition was then analyzed as the percent of X-34 stain within HJ3.4-positive plaques (termed: fibrillar plaques) and the extent of HJ3.4-positivity outside X-34 plaques (termed: Non-fibrillar plaque area). In APP/PS1x*Pld3*-KO mice, the percentage of fibrillar plaques was significantly reduced compared with APP/PS1x*Pld3*-WT mice (Figure 4.4C). Conversely, the non-fibrillar plaque area was significantly increased compared with APP/PS1x*Pld3*-WT mice (Figure 4.4D). In complementary analyses, we found that A $\beta$  plaque size was significantly increased in the cortex of APP/PS1x*Pld3*-KO compared with APP/PS1x*Pld3*-WT mice (Supplemental Figure 4.3) without a change in the overall plaque burden as defined by the percentage area of HJ3.4-positive immunostaining (e.g., plaque density). X-34 staining remained

unchanged in the absence of *Pld3* (Supplemental Figure 4.4). Thus, *Pld3* KO impacts plaque composition, shifting the pathology to a less fibrillar structure [37].

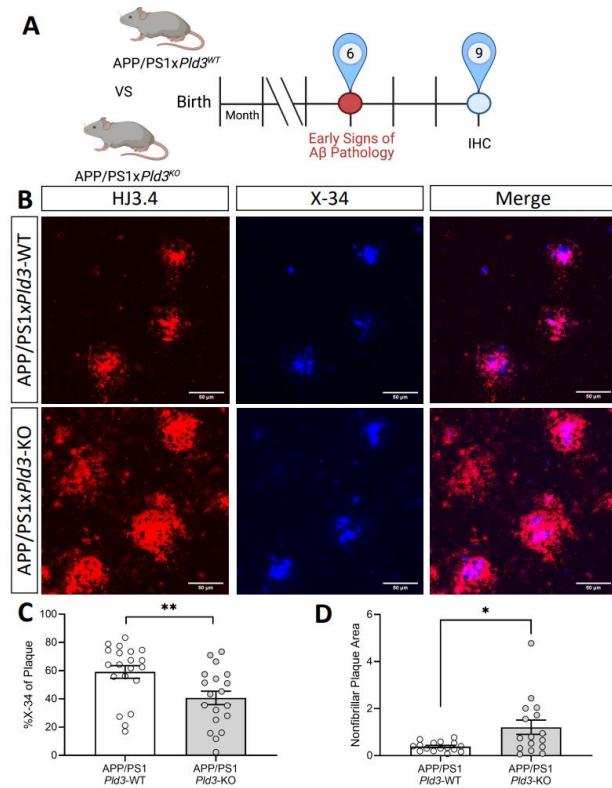

### *Pld3* deficiency impact microglial recruitment to amyloid plaques

**Table 4.1:** Differential microglia gene expression in APP/PS1x*Pld3*-KO compared with APP/PS1x*Pld3*-WT brains

Gene	Log2FoldChange	p-value
<i>Trem2</i>	0.48	1.07E-03
<i>Tyrobp</i>	0.57	1.06E-03
<i>Ctsd</i>	0.25	4.18E-03
<i>Cst7</i>	0.56	2.91E-02
<i>Cd68</i>	0.35	6.27E-02
<i>Aifl</i>	0.33	1.08E-01
<i>Tmem119</i>	0.04	6.49E-01
<i>P2ry12</i>	0.05	5.99E-01

The absence of *Pld3* in the APP/PS1 mice resulted in more non-fibrillar plaques. This shift in plaque composition is similar with findings from *Trem2*- and *ApoE*-deficient APP/PS1 mice [38-41]. Loss of these AD risk genes also significantly reduced microglial recruitment to the amyloid plaques [38-41]. Thus, we hypothesized that the loss of *Pld3* may alter the microglial response in APP/PS1 mice. To test this hypothesis, fixed brain tissue from the APP/PS1x*Pld3*-KO and APP/PS1x*Pld3*-WT mice were stained for total microglia (Iba1), activated microglia (CD68), and dense core A $\beta$  plaques (X-34) (Figure 4.5A). The amount of activated microglia as a percentage of total microglia was similar between APP/PS1x*Pld3*-KO and APP/PS1x*Pld3*-WT mice (Figure 4.5D). However, APP/PS1x*Pld3*-KO mice exhibited a significant reduction in the recruitment of microglia around the X-34-positive plaques (Figure

4.5B). No significant change was observed in the amount of CD68-positive, activated microglia around the X-34-positive (Figure 4.5C and 4.5D). *Pld3* deficient APP/PS1 mice also exhibited a significant increase in expression of microglia genes associated with neurodegeneration including *Trem2*, *Tyrobp*, *Ctsd*, and *Cst7* (Table 4.1) without a corresponding change in homeostatic microglia genes (Table 4.1). Thus, loss of *Pld3* impacts microglia function in response to amyloid plaques.

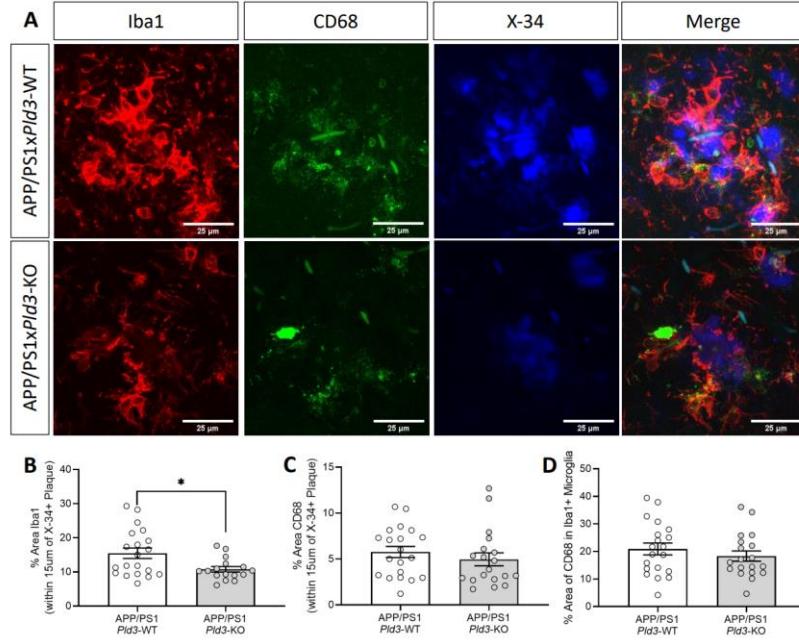

**Figure 4.4: Loss of *Pld3* alters plaque composition in APP/PS1 mouse cortex.** A. Experimental timeline. APP/PS1x*Pld3*-WT (n=20), APP/PS1x*Pld3*-KO (n=15). B. ## *A role for PLD3 in microglia*

Given the association of *Pld3* loss with altered microglia function in mouse models, we sought to determine whether *PLD3* is altered in microglia in human brains. Nuclei were isolated and sequenced from frozen AD and age-matched control brains (Figure 4.6A)[17, 18]. AD brains were further classified based on the presence of *TREM2* risk variants (named: TREM2). Unsupervised clustering of the brain nuclei revealed 15 cell-type specific clusters that correspond to the major cell-types found in the brain [17]. We isolated microglia from other cells and reexamined the alternative transcriptional states that we further classified into nine subclusters (Figure 4.6B). *PLD3* expression was significantly overexpressed in Mic.1 and reduced Mic.2 microglia subclusters compared to all microglia clusters (Figure 4.6B;  $p=2.71\times10^{-5}$  and  $2.27\times10^{-6}$ , respectively; Supplemental Table 4.2). In contrast, homeostatic microglia (Mic.0) did not show differential expression of *PLD3* (Figure 4.6B;  $p=0.52$ ; Supplemental Table 4.2). Microglia in Mic.1 have an expression signature consistent with microglia associated with neurodegeneration (e.g. disease associated or activated response microglia) [33, 42, 43], while Mic.2 clusters are enriched among *TREM2* variant carriers and exhibit upregulated resting state microglia markers with minimal elevation of genes associated with activated microglia [17].

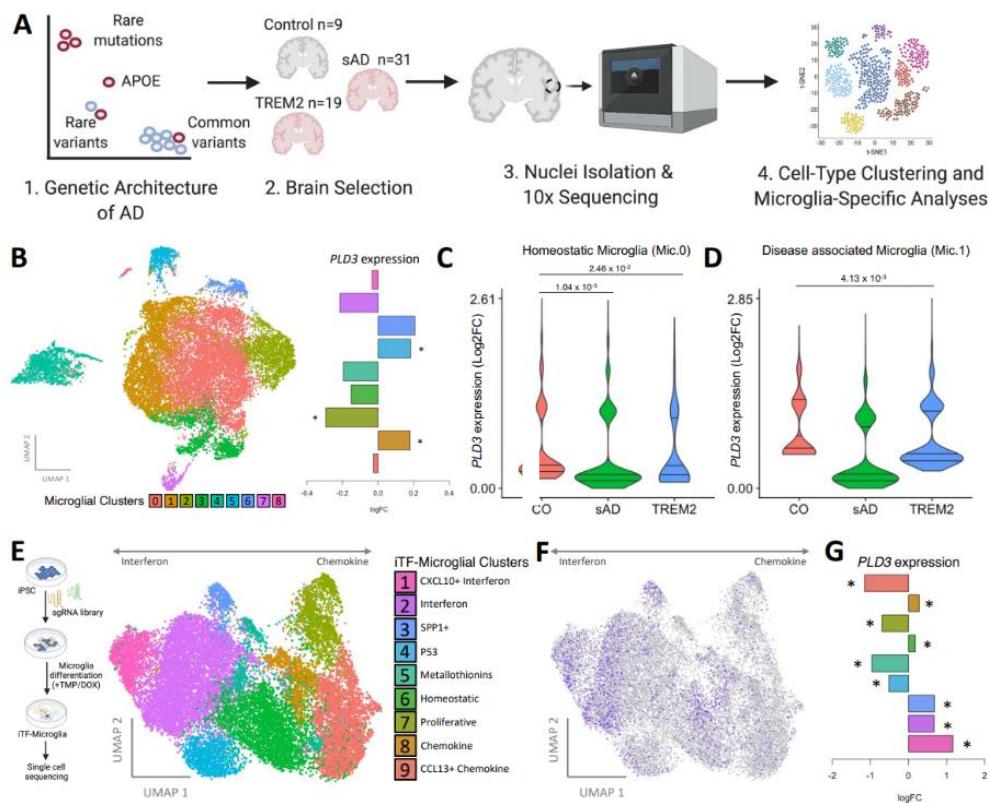

To understand how *PLD3* expression changes in microglia with disease, we examined control, sporadic AD and *TREM2* risk variant carriers. *PLD3* expression was significantly reduced in homeostatic microglia in sporadic AD brains and *TREM2* risk variants compared to controls (Figure 4.6C;  $p=1.04\times10^{-3}$  and  $p=2.46\times10^{-2}$ , respectively; Supplemental Table 4.3). *PLD3* expression was further dysregulated in disease associated Mic.1 cluster in *TREM2* risk variant carriers compared with controls (Figure 4.6D;  $p=4.13\times10^{-3}$ ; Supplemental Table 4.3).

To further clarify the relationship between PLD3 and microglia function, we analyzed *PLD3* expression in single cell RNAseq data obtained from human iPSC expressing inducible CRISPRi machinery that were transduced with 81 sgRNAs and differentiated into iTF-Microglia (Figure 4.6E) [44]. Unsupervised clustering analyses revealed nine distinct microglia subclusters (Figure 4.6E), representing distinct transcriptional states. Among these subclusters, *PLD3* was significantly overexpressed in clusters 1, 2, and 3 and significantly reduced in clusters 4, 5, 7, and 9 (Figure 4.6F and 4.6G; Supplemental Table 4.4). Clusters 1-3 correspond with interferon-induced gene activation states [44], while clusters 4-9 are enriched for genes associated with chemokine/cytokine activation states [44]. Cluster 3, where *PLD3* is significantly elevated, is enriched in *SPP1* expression, a marker of disease associated microglia [44]. Additionally, cluster 7, where *PLD3* is significantly reduced, is enriched in markers of microglia proliferation [44]. Together, these data support a role for *PLD3* in microglia activation in health and disease.

**Figure 4.5: Loss of *Pld3* alters the microglial response to Aβ pathology.** A. Representative images of APP/PS1x*Pld3*-WT and APP/PS1x*Pld3*-KO mice co-stained with Iba1 (total microglia), CD68 (activated

microglia), and X-34 ( $\beta$ -sheet-rich dense cores). APP/PS1x*Pld3*-WT (n=20), APP/PS1x*Pld3*-KO (n=19). B. Quantification of Iba1 localization within 15  $\mu$ m of the X-34+ dense core plaques (\*, p=0.03). C. Quantification of CD68 localization within 15  $\mu$ m of the dense plaques. D. Quantification of Iba1 and CD68 colocalization. Graphs represent mean  $\pm$  SEM. Analyzed by two-tailed Student's *t* test with a ROUT outlier analysis (Q=1%).

## 4.5 Discussion

In this study, we sought to understand the contribution of PLD3 to pathways that promote AD pathology. We demonstrate that the AD risk variant, *PLD3* p.A442A, is sufficient to alter *PLD3* splicing and A $\beta$  levels in iPSC-derived neurons in a manner consistent with similar findings in AD brains [4]. Additionally, we describe a role for PLD3 in LOAD, whereby modifying *PLD3* expression in APP/PS1 mice is sufficient to regulate A $\beta$  turnover in the ISF. The observed reduced ISF A $\beta$  turnover, in turn, leads to a change in amyloid plaques in aged animals. We observed that loss of *Pld3* in APP/PS1 mice results in a shift in plaque composition to a more nonfibrillar structure. This altered plaque composition is accompanied by impaired microglial recruitment to the plaques, consistent with prior reports from *Trem2* deficient mice. In human brains, *PLD3* is enriched in disease associated microglia and expression is altered in AD brains. Together, these results suggest that *PLD3* plays cell-autonomous and non-cell autonomous roles in AD pathogenesis.

Deciphering the contribution of risk variants and pathogenic mutations to AD pathogenesis has led to groundbreaking discoveries of A $\beta$  metabolism, synaptic function, and immune function to AD and revealed novel therapeutic targets [45]. Emerging sequencing technologies in increasingly larger cohorts have revealed the contribution of rare variants to AD risk [45, 46]. Nevertheless, resolving the contribution of rare variants to disease can be challenging when relying on association studies and autopsy brain tissue that captures a snapshot of disease.

Here, patient-derived cell culture models represent a tractable, human platform that recapitulates disease-specific phenotypes and when coupled with genome engineering, allows for

the study of genotype x phenotype relationships. This study demonstrates that iPSC-derived neurons are highly informative and recapitulate early pathogenic events in AD.

In this study, we used genome editing technology to molecularly pinpoint the contribution of the A allele to PLD3 and AD-related phenotypes. While we cannot exclude the possibility that genomic factors beyond PLD3 p.A442A contribute to the risk profile in the iPSC donor line used in this study, we can attribute the defect in PLD3 splicing and the increase in A $\beta$  levels to this synonymous variant. The increase in both A $\beta$ 42 and A $\beta$ 40 is consistent with the effects of other known pathogenic mutations, including APP KM670/671NL [47, 48]. The absence of an effect of *PLD3* p.A442A on the A $\beta$ 42/40 ratio suggests that A $\beta$  recycling and trafficking. This is consistent with recently reported functions of PLD3 as a type II membrane protein functioning in endosomes and lysosomes, the primary site of APP cleavage [49, 50]. Together, these human stem cell findings suggest a role for PLD3 p.A442A in altering APP/A $\beta$  recycling and trafficking in a manner that elevates total A $\beta$  levels.

PLD3 p.A442A was predicted to disrupt a splicing enhancer-binding site [4]. We observe defective *PLD3* splicing in iPSC-derived neurons from a *PLD3* p.A442A carrier, which replicates the observations in brains from *PLD3* p.A442A carriers [4]. We go on to demonstrate that correcting the risk allele with CRISPR/Cas9 is sufficient to restore the splicing defect. The functional impact of distinct PLD3 isoforms remains unknown; however, as the functional roles of PLD3 are resolved, this will be an important area to explore.

We show that PLD3 is a major regulator of ISF A $\beta$  turnover *in vivo*. Hippocampal reduction of endogenous *Pld3* in adulthood via AAV8-mediated knockdown or global knockout of *Pld3* in the background of APP/PS1 mice resulted in a strong increase in ISF A $\beta$  half-life,

suggesting that A $\beta$  is turned over more slowly in the absence of *Pld3*. A $\beta$  clearance mechanisms have been proposed to drive LOAD [35]. Following secretion from presynaptic neurons, A $\beta$  is either taken up and degraded in the lysosomes of post-synaptic neurons, taken up and degraded in the lysosomes of glial cells, degraded by extracellular proteases, is transported to CSF, or transcytosed across the blood-brain barrier (BBB). Amyloid accumulation occurs in an A $\beta$  concentration-dependent manner [36]; thus, dysregulation of ISF A $\beta$  clearance drives amyloid accumulation and AD pathogenesis. Neurons from *Pld3* KO mice exhibit lysosomes with increased density and size [33]. PLD3 is enriched in lysosomes surrounding amyloid plaques in human AD brains and mouse models of amyloid accumulation [9]. Thus, *Pld3* may regulate ISF A $\beta$  through lysosome-mediated clearance mechanisms in neurons or other glial cells.

The absence of *Pld3* in APP/PS1 mice led to a shift in the composition of amyloid plaques to being more diffuse and less fibrillar. While amyloid plaques may adopt a series of morphologies and architecture, a major structure is characterized by a dense “fibrillar” core of A $\beta$  surrounded by more diffuse “non-fibrillar” of A $\beta$  deposits [51]. Non-fibrillar A $\beta$  is proposed to contribute to its higher toxicity, possible because either its structure is more toxic or they serve as a reservoir for more diffusible A $\beta$  oligomers [37, 52]. Thus, a PLD3-mediated shift to more non-fibrillar plaques is consistent with more toxic effects given the same amount of overall A $\beta$  deposition. Silencing AD risk genes, including *Trem2* and *ApoE*, result in a similar shift of plaque composition shift in APP/PS1 mice [38, 39, 41]. Thus, modeling the reduction of *PLD3* observed in *PLD3* p.A442A carriers, and LOAD brains in an animal model of amyloid accumulation leads to a phenotype consistent with a gene that exacerbates disease.

In prior studies where gene silencing in amyloid mice led to a change in plaque formation and composition, a role for an altered microglial response to amyloid plaques was implicated

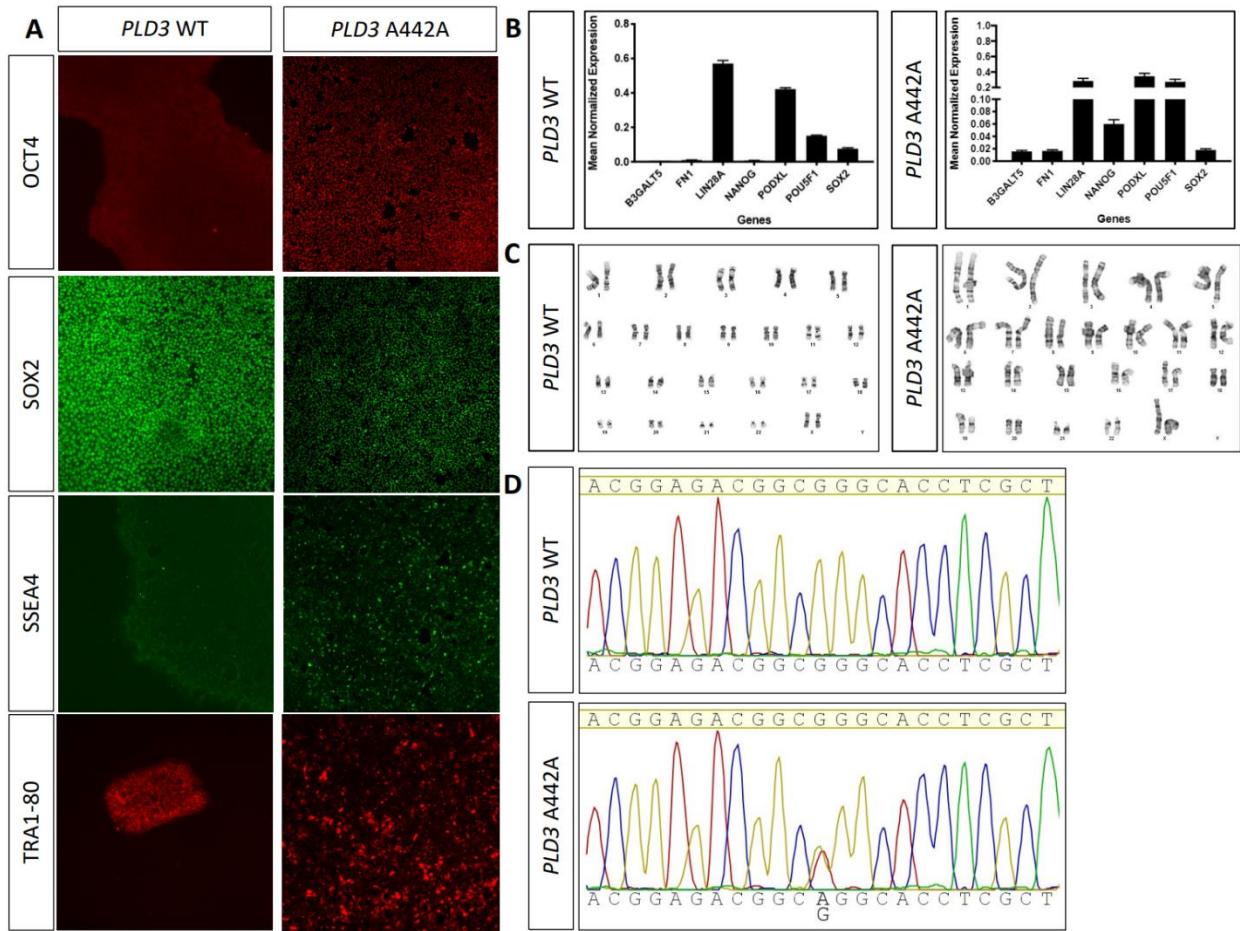

[38, 39, 41]. APP/PS1x*Pld3*-KO and APP/PS1x*Pld3*-WT mice exhibited a similar abundance of Iba1 positive microglia. Yet, recruitment of Iba1-positive microglia to X-34-positive plaques was significantly reduced in APP/PS1x*Pld3*-KO mice compared to APP/PS1x*Pld3*-WT mice. This could suggest a role for PLD3 in recruiting microglia to surround and alter A $\beta$  structure and limit A $\beta$ -induced toxicity similar to mechanisms described for TREM2 [38]. In mice, *Pld3* mRNA is expressed in microglia [53]. Microglia isolated from amyloid mouse models (APP<sup>NL-F-G</sup>) reveal an activation state enriched for MHC class II, tissue repair genes, and enrichment of AD risk genes, including *Pld3* [54]. Thus, loss of *Pld3* in the global knockout may impact the molecular identity of microglia, which impairs the recruitment and responsiveness of the glia to plaques.

In human microglia, PLD3 plays a role in microglia that is disrupted in AD. Microglia maintain distinct transcriptional states that likely reflect functional changes due to environmental stimuli [55]. We demonstrate that *PLD3* expression is enriched in disease associated microglia (Brain Mic.1 and iTF-Microglia cluster 3) and depleted in population of microglia that are found in *TREM2* risk variant carriers (Brain Mic.2). Mic.2 reflect a dampened activation state, distinct from homeostatic microglia (Mic.0) with an upregulation of resting state microglia markers (*TMEM119*, *P2RY13*, *MED12L*) and modest elevation of activated markers (*ABCA1*, *C5AR1*, and *CD83*) [17]. This finding along with the observation that *PLD3* expression is reduced in disease associated microglia (Mic.1) in *TREM2* risk variant carriers suggests a potential interaction between these AD risk genes. These results also support the parallels between our mouse model findings and those in *Trem2* deficient mice. In addition to association with disease associated microglia, PLD3 and TREM2 have also been implicated in lysosomal function [9, 33, 40, 49, 50].

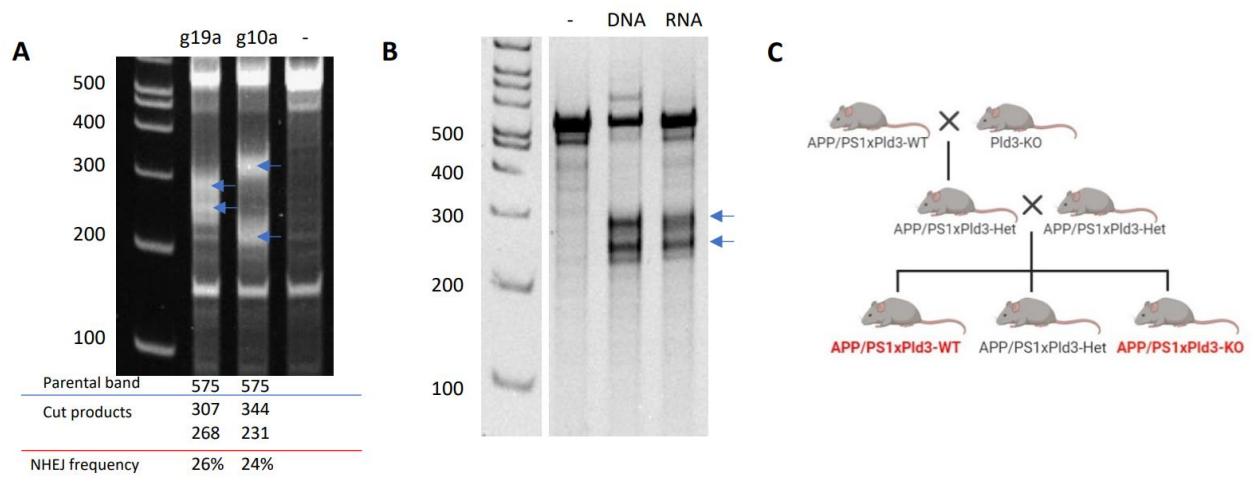

Overall, we observed a modest impact on amyloid plaque pathology in APP/PS1x*Pld3*-KO mice. The modest impact is highly consistent with PLD3 as a disease modifier rather than a fully penetrant, causative mutation. Alternatively, this could reflect redundant mechanisms for mouse *Pld3*.

Here, we demonstrate a therapeutic potential for PLD3. *hPLD3* overexpression by AAV8 in APP/PS1 mice resulted in a significant decrease in ISF A $\beta$  levels and accelerated A $\beta$  turnover. *PLD3* levels are significantly reduced in AD brains, and *PLD3* expression is positively correlated with cognition in humans and mouse models [9]. Thus, by promoting A $\beta$  turnover and facilitating the microglial response to amyloid plaques, *PLD3* occupies a crucial role in brain health.

4.8

## **Chapter 5: Conclusions**

## **5.1 Introduction**

Since it was first observed and characterized by Aloysius Alzheimer back in 1908, Alzheimer disease (AD) has remained one of the biggest medical challenges to humanity. However, the lack of effective therapeutics should not be mistaken as a lack of understanding of the disease. Over decades of AD research, significant contributions have been made to the understanding of AD genetics and core disease mechanisms. Through these efforts, the research has been able to shed light on the breadth of genes that affect AD, the cellular pathways involved, and the mechanistic steps that drive disease. In this dissertation, I outlined our work in expanding our knowledge through three genes: *LMNA*, *RAB10*, and *PLD3*.

## **5.2 Dissertation work furthers research into genetics driving AD pathology**

### *LMNA and the role of nucleoskeletal integrity in AD*

When studying a particular disease, much can be gained from looking at similar diseases that share characteristics. A perfect example of this is the nucleoskeletal dysfunction observed in AD that occurs in more well-studied laminopathies. In **Chapter 2**, we demonstrate how mRNA expression from laser-captured microdissected neurons leads to dysregulation in the expression of *LMNA* and *ZMPSTE24*, causing an imbalance of mature lamin A protein in a manner that resembles what is observed in Hutchinson Guilford Progeria Syndrome (HGPS). As a result, the many of the same nucleoskeletal dysfunction observed in HGPS is also observed in AD [1, 2]. This can result in changes in the nucleoskeletal dysfunction, such as the formation of tubular

invaginations in the nuclear membrane [3]. These alterations to the nuclear shape can cause changes to chromatin structure, abnormal gene expression, and increased DNA damage [1, 2, 4]. Furthermore, when HGPS was induced in iPSC-derived neurons through forced progerin expression, many of the genes disrupted by progerin were found to match those disrupted in AD, notably lysosomal signaling. Irregularities in the structure of the nuclear lamina can also be caused by influences outside the nucleus, such as alterations to the cytoskeleton driven by tau accumulation can also alter the nuclear lamina through the linker of nucleoskeleton and cytoskeleton (LINC) complex [3]. Therefore, while nuclear defects are observed in AD, it is yet to be seen whether such changes occur as the result of AD pathology or vice versa.

*RAB10 variant rs142787485 may confer resilience to AD through a miRNA-centric pathway*

As we learn more about the genetics of AD, we must also dedicate our efforts to identifying variants that protect against AD, for understanding such variants could grant us invaluable insight for the development of therapeutics that emulate the mechanistic elements of these variants. In **Chapter 3**, we discuss an example of such a variant and how it may confer resilience to disease. A SNP in the 3'-UTR of *RAB10*, rs142787485, was identified when studying the genomes of individuals at least 75 years old and cognitively normal despite carrying at least a single copy of *APOE4*, which is associated with at least a 3-4 fold increase in disease risk. In the original study, silencing of *RAB10* resulted in a shift of the ratio of A $\beta$ 42/40 in a manner that was less prone to aggregation [5]. In agreement with this, RAB10 protein levels were elevated in AD brains, leading us to hypothesize that overexpression of *RAB10* was conducive to AD development and the rs142787485 SNP acted opposite to this by reducing

expression. However, unexpectedly, the SNP was found to have no effect on mRNA expression of *RAB10* and there was no significant allele specific expression between WT and SNP alleles. This leads us to consider post-transcriptional regulation of *RAB10* expression, such as miRNA. Rs142787485 is predicted to disrupt the binding of six miRNAs. However, further biochemical verification is required to investigate this possibility further.

As a member of the Rab family of GTPases, *RAB10* serves as a key regulator of subcellular vesicle and trafficking pathways, from the regulation of ER dynamics to the regulation of recycling endosome tubulization and endosomal function and recruitment of CNT-1 [6-8]. *RAB10* is also associated with lysosomal secretion during stress [9] and requires phosphorylation at threonine 73 (T73) by leucine rich repeat kinase 2 (*LRRK2*), a known risk gene in Parkinson's disease [10]. This is especially intriguing because APP processing occurs within many of these same compartments [11]. Additional protective factors associated with reduced AD risk are also function proximally to the process of APP metabolism, such as the *APP* A673T mutation [12] or the *APOE* R136S Christchurch mutation [13, 14].

### *PLD3 alters the microglial response and amyloid pathology as a response*

In **Chapter 4**, using both *in vitro* and *in vivo* systems, we investigated the role of *PLD3*, an enzyme with genetic variants that were associated with disease risk. Using iPSC-derived cortical neurons, we show that the silent mutation *PLD3* A442A was sufficient to both alter the splicing of *PLD3* and omit exon 11, in corroboration to what was observed in the brains of carriers [15], and increase overall secreted A $\beta$  levels. Furthermore, when *Pld3* expression was reduced in an amyloid mouse model, the overall turnover of A $\beta$  was significantly inhibited, implying that *Pld3* played an important role in the clearance of A $\beta$ . When *Pld3* was knocked out

in this same mouse model, we also observe a change in the microglial response, demonstrated by a significant decrease in microglial recruitment around amyloid plaques. This altered microglial response leads to a shift in the overall makeup of amyloid plaques, resulting in plaques that are less fibrillary and more diffuse in nature, which have been shown to be more toxic overall. This is found to mirror what is observed in amyloid mouse models deficient for *Trem2* [16], a gene found to play an important role in the activation of disease associated microglia (DAM) [17], and when we ran an RNAseq analysis on our amyloid mice deficient for *Pld3*, we observed a shift in expression of genes associated with the DAM response. Furthermore, when we looked at snRNAseq data from human brains, we find upregulation of *PLD3* in activated microglia, further establishing that *PLD3* plays an important role in the microglial response to disease. Conversely, microglia with mutant *TREM2* expressed reduced microglial levels, also establishing the link we are observing between *PLD3* and *TREM2*. Considering this, it may be possible that therapeutic strategies that have been developed for *TREM2*-mediated processes can be leveraged to target *PLD3* as well.

### **5.3 Future directions: linking AD genetics, intracellular and extracellular processes, and AD pathology**

The genetics of LOAD is incredibly complex. In the scope of the work outlined in this dissertation, we examine seemingly disparate genes and how they ultimately drive AD risk. From looking at the genetics, much can be learned about these disease-relevant pathways and how they relate to each other. For example, while we discuss the roles played by nucleoskeletal integrity (**Chapter 2**) and the endo-lysosomal network (**Chapter 3**), it must also be remembered how these pathways are interconnected. Nutrient sensing between the lysosome and the nucleus

control energy metabolism [18] and TFEB-mediated lysosomal biogenesis requires tightly controlled signaling between both the lysosome and the nucleus [19].

Additionally, we examine the contribution of AD risk genes to processes outside of the neuron, with our findings showing how *PLD3* drives the microglial response to A $\beta$  (**Chapter 4**). This provides compelling support for investigations into the contribution of glia cells to AD pathogenesis. Therapeutic approaches that target nuclear-endo-lysosomal networks and promote glia function build off key genetic findings and hold promise for the future.

# Curriculum Vitae

Matthew James Rosene

[mjrosene@wustl.edu](mailto:mjrosene@wustl.edu)

PhD Candidate

Department of Psychiatry

Washington University in St. Louis School of Medicine

425 S. Euclid Ave, Campus Box 8134

St Louis, MO 63110

**Citizenship:** USA

## **Education:**

**Washington University**, St Louis, MO, US

PhD Candidate, Molecular Cell Biology

Mentor: Dr. Celeste M Karch

**Luther College**, Decorah, Iowa, USA

BA, *cum laude*, Biology, May 2015

## **Positions:**

2018-present Doctoral student in the laboratory of Celeste Karch, St Louis, MO

2016-2018 Doctoral student in the laboratory of Zhongsheng You, St Louis, MO

2015-present PhD Student in the Division of Biology and Biomedical Sciences at Washington University, St. Louis, MO

2014 Undergraduate research intern in the laboratory of Bryan Phillips, Iowa City, IA

2013 Undergraduate research intern in the laboratory of Thomas Rutkowski, Iowa City, IA

## **Selected Honors:**

2021 Travel Fellowship, Alzheimer's Association International Conference

2016-2018 Cell and Molecular Biology Training Grant Recipient

2014 University of Iowa Summer Undergraduate Research Program Intern

**Supervising, Teaching, and Science Outreach:**

2019 Summer Mentor for the Biomed RAP Undergraduate Research Program, Madhavi Jere

2017 Teaching Assistant for General Biology, Washington University in St. Louis, St Louis, MO

2014 Undergraduate Lab Assistant, Molecular Biology, Luther College, Decorah, IA

**Conference Abstracts**

2021 Defining the role of phospholipase D3 in Alzheimer disease pathogenesis (Talk), AAIC Next Virtual Conference

2021 Defining the role of phospholipase D3 in Alzheimer disease pathogenesis (Talk), Alzheimer's Association International Conference, Denver, CO

2021 LMNA-mediated nucleoskeleton dysregulation in Alzheimer's disease (Poster), Alzheimer's Association International Conference, Denver, CO

2021 Defining the role of phospholipase D3 in Alzheimer disease pathogenesis (Talk), Chan-Zuckerberg Initiative Neurodegenerative Challenge Network Virtual Conference

2021 LMNA-mediated nucleoskeleton dysregulation in Alzheimer's disease (Poster), Washington University Virtual Psychiatry Residency Research Education Program Research Day Symposium

2020 LMNA-mediated nucleoskeleton dysregulation in Alzheimer's disease (Poster), Cold Springs Harbor Laboratory Virtual Conference for Neurodegenerative Diseases: Biology and Therapeutics

2020 LMNA-mediated nucleoskeleton dysregulation in Alzheimer's disease (Poster), Chan-Zuckerberg Initiative Neurodegenerative Challenge Network Virtual Conference

2014 Prevalence of Multi-Drug Resistant (MDR) Bacteria in North East Iowa Streams (Talk), Iowa Academy of Sciences Research Symposium, Fort Dodge, IA

**Professional Service:**

2020-Present Member of the LouHealth Advocacy group Criminal Justice Reform Team

2019 Poster Judge, Biomed RAP Summer Symposium

**Societal Membership:**

βββ Biological Honor Society

**Technical Skills:**

**Molecular Biology:** SDS-PAGE, Western blotting, protein purification, PCR, RNA purification, reverse transcription and quantitative PCR, plasmid construction and cloning, DNA radiolabeling

**Cell and Tissue Biology:** Mammalian cell culture, stable and transient transfections, virus production and transduction, immunocytochemistry, confocal and fluorescence microscopy

**Animals:** *Xenopus laevis* handling, extract preparation from *Xenopus laevis* eggs, *Caenorhabditis elegans* handling, *mus musculus* handling, *Mus musculus* brain tissue harvesting

**Peer-Reviewed Publications:**
