

Boosting electrical conductivity in a gel-derived material by nanostructuring with trace carbon nanotubes

Submitted by Emmanuel Lemoine on Thu, 02/06/2014 - 14:07

Titre	Boosting electrical conductivity in a gel-derived material by nanostructuring with trace carbon nanotubes
Type de publication	Article de revue
Auteur	Canevet, David [1], del Pino, Ángel Pérez [2], Amabilino, David-B. [3], Sallé, Marc [4]
Editeur	The Royal Society of Chemistry
Type	Article scientifique dans une revue à comité de lecture
Année	2011
Langue	Anglais
Numéro	7
Pagination	2898-2902
Volume	3
Titre de la revue	Nanoscale
ISSN	2040-3364
Résumé en anglais	An organogelator with two distinct [small pi]-functional units is able to incorporate carbon nanotubes into its mesh of fibres in the gel state. The morphology of the material derived from this nanocomposite after evaporation of the solvent is a complex mesh of fibres which is clearly different from the pure gelator. This feature indicates a role of the nanotubes in assisting the formation of a fibre structure in the gel thanks to their interaction with the pyrene units in the organogelator. The nanocomposite conducts electricity once the p-type gelator is doped with iodine vapour. The change in morphology caused by the carbon material increases the conductivity of the material compared with the purely organic conducting system. It is remarkable that this improvement in the physical property is caused by an extremely small proportion of the carbon material (only present at a ratio of 0.1% w/w). The practically unique properties of TTF unit allow measurements with both doped and undoped materials with conducting atomic force microscopy which have demonstrated that the carbon nanotubes are not directly responsible for the increased conductivity.
