

# PIPE-cloned human IgE and IgG4 antibodies: New tools for investigating cow's milk allergy and tolerance

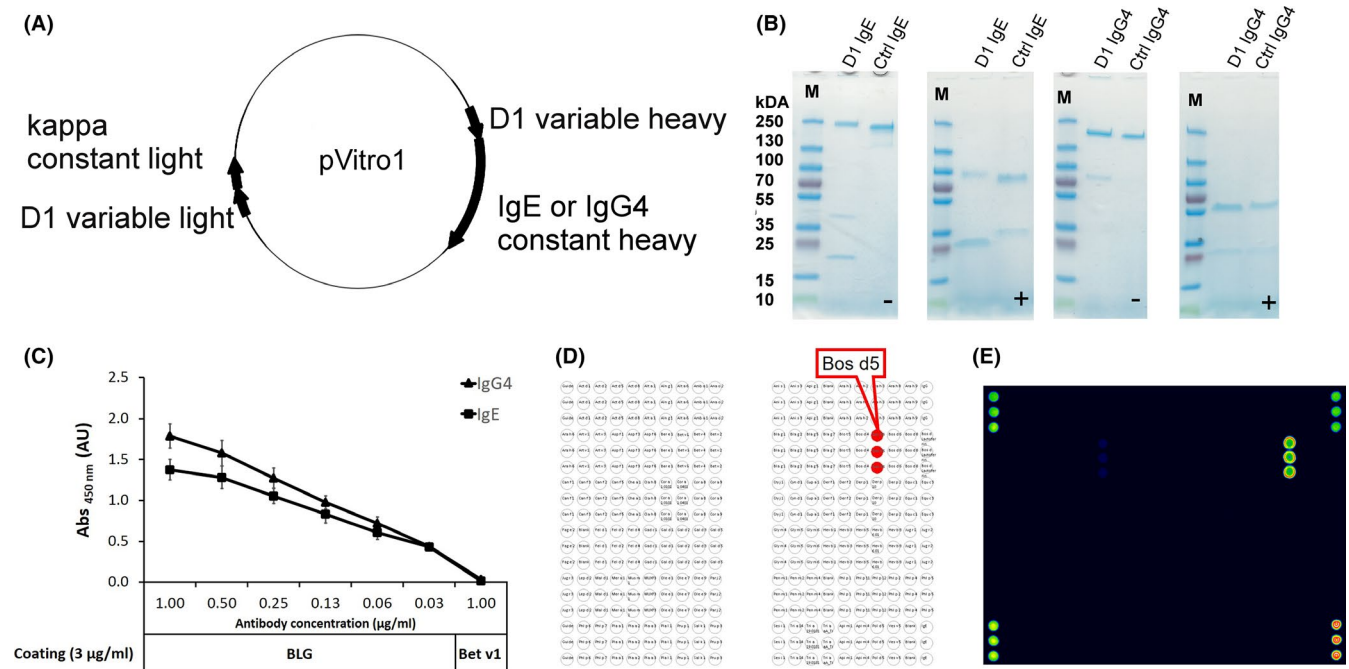

To the Editor,

Cow's milk (CM) allergy (CMA) is defined as an immune-mediated adverse response to CM proteins.

2% to 3% of children are suffering from CMA, but many develop natural tolerance after 3-4 years.<sup>1,501</sup> Food allergen immunotherapy (FA-AIT) applying increasing antigen doses (oral immunotherapy, OIT) can contribute to improvement of CMA,<sup>502</sup> with variable clinical efficacy,<sup>2,503</sup> but immunologically often resulting in decreased specific IgE levels and increased specific IgG4 levels<sup>504,505</sup>. IgG4 is (a) anti-inflammatory as it does not activate the complement system; (b) bi-specific due to fab-arm exchange and, thus, has less crosslinking capacity than IgE, but has (c) blocking capacity.<sup>3</sup> The interplay of IgE and IgG4 may hence be decisive for the immune balance in CMA.

Antibodies of different isotypes with the same variable region could be essential in molecular studies of the mechanism underlying CMA and might shed light onto the function of specific IgG4 antibodies during the acquisition of tolerance.

Polymerase Incomplete Prime Extension (PIPE) cloning is a cutting-edge technique to engineer antibodies against various targets and facilitates simple exchange of the constant regions to increase the range of subtypes of antibodies.<sup>4-6</sup> In this study, we combined variable regions from the high-affinity IgE antibody "D1"<sup>7</sup> ( $K_D = 1.4 \times 10^{-9}$  M;  $k_{on} = 1.4 \times 10^6$ ,  $k_{off} = 1.54 \times 10^{-3}$ )<sup>506</sup> specific for the major CM allergen beta-lactoglobulin (BLG), with the constant domains of IgE or IgG4 antibodies (Figure 1A). Correct antibody assembly was confirmed by SDS-PAGE in comparison with commercial

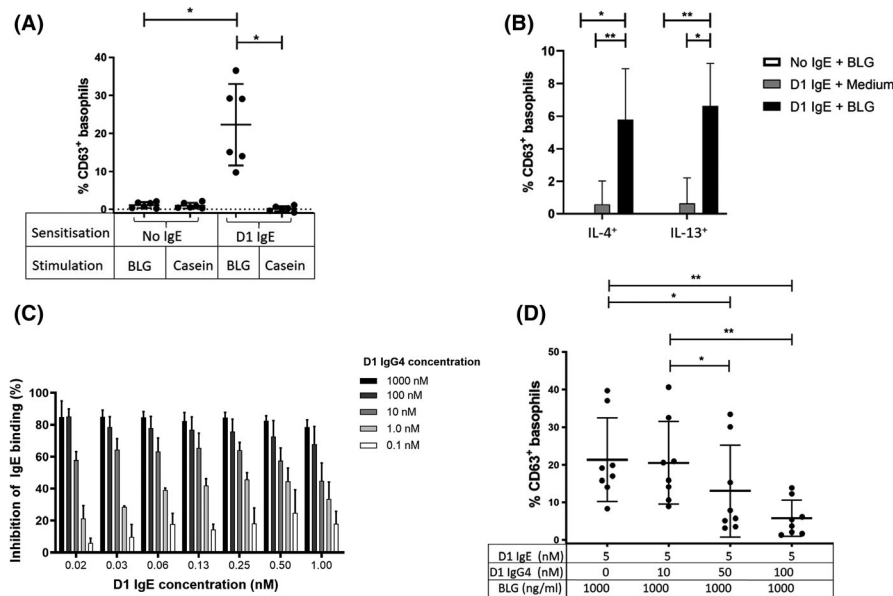

**FIGURE 1** Correct assembly and BLG-specific binding of PIPE-cloned D1 IgE and IgG4 antibodies. A, Schematic overview of the pVItro1 antibody constructs for the production of D1 IgE and IgG4. B, SDS-PAGE of D1 antibodies in comparison with commercial isotype antibodies under nonreducing (-) and reducing condition (+). C, Specificity of D1 anti-BLG antibodies in an ELISA. 3 µg/mL of BLG or Bet v 1 (control) were coated onto ELISA plates, and binding of respective D1 antibodies at different concentrations was determined. Data represent the mean of three independent experiments, and error bars indicate SD. D, Overview of ISAC112 microarray layout. E, Specific binding of D1 IgE to BLG (Bos d 5) in ISAC112

**Abbreviations:** AIT, allergen immunotherapy; BAT, basophil activation test; BLG, beta-lactoglobulin; CM, cow's milk; CMA, cow's milk allergy; D1, name of engineered antibodies due to their published, variable regions; ELISA, enzyme-linked immunosorbent assay; FA-AIT, food allergen immunotherapy; IL, interleukin; ISAC, Immuno-Solid phase Allergy Chip; OIT, oral immunotherapy; PBMC, peripheral blood mononuclear cells; PIPE cloning, polymerase incomplete primer extension cloning; RT, room temperature; SDS-PAGE, sodium dodecyl sulphate-polyacrylamide gel electrophoresis; TBS, Tris-buffered saline; TBS-T, TBS-Tween; UHT milk, ultra-high temperature processed milk.

**FIGURE 2** Functionality testing of D1 IgE in passively sensitised basophils: CD63 upregulation and intracellular cytokine production and blocking capacity testing of D1 IgG4: blocking of IgE binding in ELISA and inhibition of IgE crosslinking in BAT in a concentration-dependent manner. A, Stripped and IL-3 primed basophils from six healthy donors, native or passively sensitized with 5 nmol/L D1 IgE were triggered with BLG, or casein control, both at 1000 ng/mL. Control experiments were performed in the absence of IgE. Normal distribution was confirmed by Shapiro-Wilk normality test and differences between the groups assessed with repeated measures ANOVA with Greenhouse-Geisser correction and Sidak multiple comparison test:  $F(1.022, 5.110) = 24.01$ ,  $P = .0041$ . Gating strategy: See Figure S3, supplement. B, IgE-stripped and IL-3 primed basophils of healthy donors, native or passively sensitized with 5 nmol/L D1 IgE, were stimulated with 1000 ng/mL BLG or medium control. Y-axis: percentage of CD63<sup>+</sup> cells, x-axis: levels of intracellularly expressed cytokines. Differences in the groups were statistically analysed using two-way ANOVA with Greenhouse-Geisser correction:  $F(1.276, 6.382) = 45.27$ ,  $P = .0003$  and a Bonferroni multiple comparison test. \* $P < .05$ , \*\* $P < .01$ , and \*\*\* $P < .001$ . Gating strategy: See Figure S3, supplement. C, BLG was coated onto ELISA plates, D1 IgG4 added in increasing concentrations (see colour code for white to black columns), and then D1 IgE added in various concentration as shown on x-axis. Bound IgE was detected by HRP-labelled anti-human-IgE antibody. Data represents the mean  $\pm$  SD of three independent experiments. D, Percentage of CD63<sup>+</sup> activated basophils in eight healthy donors (y-axis) after IgE-stripping, IL-3 priming, sensitising with 5 nmol/L BLG-specific D1 IgE and subsequent stimulation with 1000 ng/mL BLG alone, or BLG mixed with 0-100 nmol/L D1 IgG4 antibodies, as described in the x-axis. Significant differences were assessed with the Friedman test:  $\chi^2(4) = 19.80$ ,  $P = .0002$ ,  $n = 8$  and Dunn's multiple comparison test \* $P < .05$ , \*\* $P < .01$ , and \*\*\* $P < .001$ . Gating strategy: see Figure S3, supplement

antibodies of the same isotype (Figure 1B). The exclusive specificity of D1 antibodies was proven in ELISA (Figure 1C), in ISAC112 microarray (Figure 1D,E) and in ImmunoCAP (data not shown). Antibodies were furthermore species-specific to bovine BLG when testing milk samples from various animal species and showed a sensitivity comparable to a commercial anti-BLG-ELISA (Figure S1).

We next applied our antibodies for the quantification of BLG-specific IgE and IgG4 antibodies in serum of milk allergic patients ( $n = 9$ ) and sensitised but tolerant patients ( $n = 8$ ). Allergic children had significantly higher levels of IgE ( $P < .01$ ), but no differences in the IgG4 levels were seen between the groups (Figure S2), in accordance with previous studies.<sup>8</sup> Our data suggest that the PIPE-cloned antibodies may be useful for a precise quantification of allergen-specific IgE and IgG4. This is advantageous, as specific IgE is usually quantified by comparing the reactivity to IgE absorbed to a solid phase, likely leading to an underestimation of specific IgE and semi-quantitative results.

Basophil activation test (BAT) is a reliable method to evaluate functional capacities of antibodies, allowing at least an approximation to the real-life situation of an allergic patient. When IgE-stripped basophils from healthy donors were sensitised with D1 IgE antibodies and triggered with BLG, basophil activation levels comparable to

primary basophils from milk allergic patients in other studies were achieved.<sup>9</sup> Activation of the basophils, measured by the surface expression of the activation marker CD63, was specifically seen after stimulation with BLG, but not with the control milk allergen casein ( $P < .05$ ; Figure 2A) and this was associated with increased production of the intracellular Th<sub>2</sub> cytokines IL-4 ( $P = .0187$ ) and IL-13 ( $P = .0048$ ; Figure 2B). Overall, the results propose that our IgE antibodies are functional and may be useful tools to standardise BAT assays to achieve comparability between different laboratories.

The blocking capacity of D1 IgG4 antibodies was investigated in an ELISA. As expected, the D1 IgG4, harbouring the same variable region, could decrease D1 IgE binding to plate-bound BLG in a concentration-dependent manner (Figure 2C). In accordance with these results, D1 IgG4 inhibited the activation of IgE-stripped, IL-3 primed, D1 IgE-sensitised and BLG-stimulated basophils from healthy donors in a dose-dependent manner. The addition of 50 nmol/L ( $P = .0402$ ) or 100 nmol/L D1 IgG4 ( $P = .0029$ ) significantly decreased the percentage of CD63<sup>+</sup> basophils (Figure 2D). In agreement with others, our findings confirmed the importance of the IgG4:IgE-ratio, as no inhibition was achieved with the lowest concentration of D1 IgG4 (10 nmol/L). In line with our D1 IgE/D1 IgG4-model, overlapping epitope-binding of IgG4

and IgE antibodies may play an essential role in acquiring tolerance.<sup>8</sup> At the same time, this is also the limitation of our molecular model: the situation in allergic patients with polyclonal antibodies, binding to various epitopes on the allergen, is more complex. However, in a parallel study, with a PIPE-cloned monoclonal IgG4 against the major birch pollen allergen Bet v 1, we were able to demonstrate its blocking capacity using the sera from birch allergic patients.<sup>507</sup>

Whether the IgG4 antibodies could be applied as passive immunotherapy in cow milk allergic patients depends on a thorough risk-benefit analysis, but studies in cat allergy promise that this might be possible in the future.<sup>508</sup>

Our antibodies have so far proven valuable not only for the quantification of BLG and BLG-specific human serum antibodies, but also for functional studies. With these tools, some questions could be addressed in the future: Are IgG4 antibodies involved in the establishment of *persisting* tolerance, or in primary tolerance to milk? Contrasting results about the efficacy of oral immunotherapies for CMA may be explained by differences in the methods regarding the duration of the intervention, dosages of the allergen or the composition of the milk. The PIPE-cloned antibodies presented here may add to the comparability of such studies between laboratories. Another application of the D1 antibodies may be in studies on the effect of milk processing on immune responses. Food processing can massively influence the structure of the allergens and therefore alter their allergenicity.<sup>509,510</sup> Especially during heat processing, important BLG epitopes are lost, but IgE binding is significantly increased after pasteurisation.<sup>511</sup> Overall, the generated antibodies may shed light on milk allergenicity, bring critical insight into the development of CMA and help developing prevention strategies.

#### ACKNOWLEDGMENTS

We would like to thank Gerlinde Hofstetter for her excellent help in the laboratory and Mira Matz for her assistance with antibody purification. We acknowledge Iñigo Terrén, Joana Vitallé and Ane Orrantia for their practical assistance and interesting discussions at the Biocruces Bizkaia Health Research Institute, Barakaldo, Spain.

#### CONFLICT OF INTEREST

EJJ is founder and shareholder of Biomedical Int. R+D GmbH, Vienna, Austria, and business partner of Bencard Allergie GmbH, Germany as well as AllergyTherapeutics Ltd., UK, but has no COI in relation to the presented work. EJJ also holds patents in lipocalins including BLG for allergen immunotherapy. SNK is founder and shareholder of Epsilogen Ltd. and holds patents on IgE antibodies for cancer therapy. AF is conducting research supported by Danone SA and Hipp GmbH. He has been in the advisory boards of Abbott SA and Hipp GmbH over the last two years. The other authors have no potential conflicts of interest to disclose.

#### FUNDING INFORMATION

This work was supported by the Austrian Science Fund (FWF) grants MCCA W1248-B30 and SFB F4606-B28 to EJJ. CP received a short-term research fellowship of the European Federation of Immunological

Societies (EFIS-IL) for a research visit at Biocruces Bizkaia Health Research Institute, Barakaldo, Spain. VKK received an EFIS-IL short-term research fellowship for a research visit at King's College London. The research was funded by the National Institute for Health Research (NIHR) Biomedical Research Centre (BRC) based at Guy's and St Thomas' NHS Foundation Trust and King's College London (IS-BRC-1215-20006) (SNK). # Prostaglandin E2 decreases basophil activation in patients with food-induced anaphylaxis

To the Editor,

Adult-onset food allergy may manifest as anaphylaxis in up to half of patients in some series.<sup>1</sup> Mast cells and basophils are known to mediate immunoglobulin E (IgE)-dependent anaphylaxis. Food-induced anaphylaxis (FAn) is only partially determined by the level of allergen sensitization and can occur with low specific IgE.<sup>2</sup> This finding suggests that anaphylaxis depends at least in part on immunomodulators that regulate the intensity of the reactions.<sup>2</sup> However very little is known on the role of immunomodulators in the prevention of FAn. Mast cells/basophils can be a source of autocrine regulators to suppress excessive cell degranulation such as prostaglandin E<sub>2</sub> (PGE<sub>2</sub>).<sup>2</sup> Previous observations showed that misoprostol (PGE<sub>1</sub> agonist) inhibits mast cell/basophil activation and proved to be clinically effective.<sup>3</sup> Observations in humans animal models and in vitro studies have demonstrated that PGE<sub>2</sub> abrogates allergen-induced mast cell activation.<sup>2,4,5</sup> However it has also been shown that PGE<sub>2</sub> may have opposite effects exacerbating or inhibiting antigen-mediated reactions depending on the ratio of the four PGE<sub>2</sub> receptors (EP1-EP4) expressed.<sup>6,7</sup>

We hypothesize that a defective PGE<sub>2</sub> metabolism is involved in the development of FAn and that exogenously administered PGE<sub>2</sub> can

stabilize allergen-induced basophil activation (BA). Thus we aimed to test in patients with FAn related to peach lipid transfer protein (Pru p 3; LTP) whether (a) exogenously administered PGE<sub>2</sub> inhibits IgE-dependent basophil activation; (b) the expression profile of PGE<sub>2</sub> receptors on basophils is altered and (c) PGE<sub>2</sub> baseline plasma levels are altered as well.

Ten healthy volunteers (HV) and 25 patients were recruited based on a clinical history of anaphylaxis elicited by peach and sensitized to Pru p 3 (demographic data-Table S1). PGE<sub>2</sub> plasma levels were measured by ELISA. EP receptors gene expression was measured in isolated basophils by quantitative real-time PCR. An in vitro BA test (BAT) measured as expression of CD63 was performed with Pru p 3 anti-IgE high-affinity receptor (FcεRI) N-Formylmethionine-leucyl-phenylalanine (fMLP; 2 μM) and PGE<sub>2</sub> alone and in combination. *Detailed Methods—Online Repository*.

No differences in PGE<sub>2</sub> levels were observed (Figure S1). No EP1 (mRNA) expression was found in basophils from any group and EP2 expression was similar. EP3 was significantly increased and EP4 decreased in FAn (Figure 1A). The ratio between receptors with known pro-inflammatory (EP3) and anti-inflammatory (EP2-EP4) activity was also significantly higher in FAn (Figure 1B).
