11 Condition-dependent interaction between mating success and competitive fertilization  
12 success in *Drosophila melanogaster*. *Evolution*. <https://doi.org/10.1111/evo.14228>

13

14 **Abstract:** What conditions favor competitive outcomes at different stages of the  
15 reproductive process? De Nardo et al. (2021) found that in *Drosophila melanogaster*, the  
16 evolution of male secondary sexual traits was influenced by sexual selection through mating  
17 success and competitive fertilization.

18

19 **Main Text**

20 Sexual selection alters the overall costs of reproduction in a sex-specific manner. Male  
21 competition and female mate choice have been proposed as the principal drivers of  
22 condition-dependent evolutionary change in reproductive traits of both sexes (Andersson  
23 and Iwasa, 1996). The cost of producing ejaculate may constitute an acceptable trade-off for  
24 the reproductive benefits gained from investment in secondary sexual traits. (Parker et al.,  
25 2013). While empirical studies in support of this prediction may seem inconsistent, Simmons  
26 et al. (2017) showed how overarching patterns become apparent if additional variables are  
27 included. When females mate more than once, pre- and post-mating sexual selection can  
28 produce synergistic or antagonistic interactions. Furthermore, several studies have shown

29 how variation in condition as a result of environmental or genetic background can influence  
30 mating and fertilization success ( Liao et al., 2018, Lüpold et al., 2017, Lüpold et al., 2020).

31

32 Studying this interaction is complex, and the influence of female size on male mating and  
33 fertilization success remains a largely underexplored topic in sexual selection research. To  
34 that end, *Drosophila melanogaster*, where both sexes mate more than once, presents an  
35 ideal model system. Furthermore, females exerting mate choice before and after mating  
36 provide an excellent opportunity to explore to what extent such choice is based on variation  
37 in male and female condition, and how mating success and competitive fertilization might  
38 trade off against each other.

39

40 In this issue, De Nardo et al. (2021) test four univariate predictions about the separate  
41 effects of sex and condition on reproductive outcomes, as well as two additional predictions  
42 about sex and condition interactions (Fig.1A). High-condition, large males were predicted to  
43 be more successful in mating and have higher paternity shares than low-condition, small  
44 males. High-condition (i.e. large) females, being better equipped to invest more time and  
45 energy in mate selection, were predicted to take longer to choose a mate and to  
46 preferentially store sperm of larger males. For interactions between sex and condition, high-  
47 condition, large females were predicted to choose larger males and demonstrate a stronger  
48 bias in fertilization success for their preferred mate. To test their hypotheses, the authors  
49 conducted experiments using the genetically modified LH<sub>m</sub> strain of *Drosophila*  
50 *melanogaster* expressing either red fluorescent protein (RFP) or green fluorescent protein  
51 (GFP) in their sperm heads (Manier et al., 2013). Larvae were assigned to either a high-yeast  
52 treatment or a low-yeast treatment to enhance phenotypic variation (condition/size) in  
53 adults (Fig.1B).

54

55 De Nardo and colleagues found that, as predicted, small males were less successful in  
56 mating than their larger counterparts, but overall, were more successful in post-mating  
57 sexual selection (Fig.1C). Female condition had no effect on mate preference and mating  
58 latency, and there was no interaction between male and female conditions. High-condition  
59 females did not preferentially store sperm of larger males; however, high-condition females

60 did eject more first-male sperm when the second male was of high condition, and when the  
61 second male transferred more sperm. Male size was not found to necessarily predict sperm  
62 transfer, and female condition did not influence the preference for males in a condition-  
63 dependent manner. The authors note that these results are more telling of the experimental  
64 design than an absence of condition-dependent female mate choice.

65

66 This study by De Nardo et al. (2021) helps shine a light on the complex dynamics between  
67 pre- and post-copulatory sexual selection, secondary sexual trait evolution, and  
68 demonstrates a need to uncover additional trade-offs in between.
