HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

MCALab: Reproducible Research in Signal and Image Decomposition and Inpainting

M.J. Fadili , J.-L. Starck , M. Elad and D.L. Donoho

Abstract

Morphological Component Analysis (MCA) of signals and images is an ambitious and important goal in signal processing; successful methods for MCA have many far-reaching applications in science and technology. Because MCA is related to solving underdetermined systems of linear equations it might also be considered, by some, to be problematic or even intractable. Reproducible research is essential to give such a concept a firm scientific foundation and broad base of trusted results.

MCALab has been developed to demonstrate key concepts of MCA and make them available to interested researchers and technologists. MCALab is a library of Matlab routines that implement the decomposition and inpainting algorithms that we previously proposed in [1], [2], [3], [4]. The MCALab package provides the research community with open source tools for sparse decomposition and inpainting and is made available for anonymous download over the Internet. It contains a variety of scripts to reproduce the figures in our own articles, as well as other exploratory examples not included in the papers. One can also run the same experiments on one's own data or tune the parameters by simply modifying the scripts. The MCALab is under continuing development by the authors; who welcome feedback and suggestions for further enhancements, and any contributions by interested researchers.

Index Terms

Reproducible research, sparse representations, signal and image decomposition, inpainting, Morphological Component Analysis.

M.J. Fadili is with the CNRS-ENSICAEN-Université de Caen, Image Processing Group, ENSICAEN 14050, Caen Cedex, France.

J.-L. Starck is with the LAIM, CEA/DSM-CNRS-Université Paris Diderot, IRFU, SEDI-SAP, 91191 Gif-Sur-Yvette cedex, France.

D.L. Donoho is with the Department of Statistics, Sequoia Hall, Stanford, CA, USA.

I. INTRODUCTION

A. *Reproducible research*

Reproducibility is at the heart of scientific methodology and all successful technology development. In theoretical disciplines, the gold standard has been set by mathematics, where formal proof in principle allows anyone to reproduce the cognitive steps leading to verification of a theorem. In experimental disciplines, such as biology, physics or chemistry, for a result to be well-established, particular attention is paid to experiment replication. Of course, a necessary condition to truthfully replicate the experiment is that the paper has to describe it with enough detail to allow another group to mimic it.

Computational science is a much younger field than mathematics, but already of great importance for human welfare; however reproducibility has not yet become a rigorously-adhered to notion. The slogan 'reproducible research' is of relatively recent coinage, and tries to create a real gold standard for computational reproducibility; it recognizes that the real outcome of a research project is not the published article, but rather the entire environment used to reproduce the results presented in the paper, including data, software, documentation, etc [5]. A closely-related concept to reproducible research is computational provenance. In scientific experiments, provenance helps interpret and understand results by examining the sequence of steps that led to a result. In a sense, potential uses of provenance go beyond reproducibility; see May/June 2008 CiSE issue on this subject [6].

Inspired by Clearbout, Donoho in the early 1990's began to practice reproducible research in computational harmonic analysis within the now-proliferating quantitative programming environment Matlab; see the review paper [7] in the January/February 2009 CiSE special issue on reproducible research. In the signal processing community, the interest in reproducible research was revitalized in [8]. At one of the major signal processing conferences, ICASSP 2007, a special session was entirely devoted to reproducible signal processing research.

B. *This paper*

In this paper, reproducible research is discussed in the context of sparse-representation-based signal/image decomposition and inpainting. We introduce MCALab, a library of Matlab routines that implements the algorithms proposed by the authors in [2], [3], [4] for signal/image decomposition and inpainting. The library provides the research community with open source tools for sparse decomposition and inpainting, and may be used to reproduce the figures in this paper and to redo those figures with variations in the parameters.

Although Mathematics has its million-dollar problems, in the form of Clay Math Prizes, there are several Billion Dollar problems in signal and image processing. Famous ones include the phase problem (loss of information from a physical measurement) and the cocktail party problem (separate one sound from a mixture of other recorded sounds and background noises at a cocktail party). The "Billion Dollar" adjective refers to

the enormous significance of these problems in the world economy if these problems were solved, as well as the extreme intellectual ‘kick’ a solution would necessarily entail. These signal processing problems seem to be intractable according to orthodox arguments based on rigorous mathematics, and yet they keep cropping up in problem after problem.

One such fundamental problem involves decomposing a signal or image into superposed contributions from different sources; think of symphonic music which may involve superpositions of acoustic signals generated by many different instruments – and imagine the problem of separating these contributions. More abstractly, we can see many forms of media content that are superpositions of contributions from different ‘content types’, and we can imagine wanting to separate out the contributions from each. We can easily see a fundamental problem; for example an n -pixel image created by superposing K different types offers us n data (the pixel values) but there may be as many as $n \cdot K$ unknowns (the contribution of each content type to each pixel). Traditional mathematical reasoning, in fact the fundamental theorem of linear algebra, tells us not to attempt this: there are more unknowns than equations. On the other hand, if we have prior information about the underlying object, there are some rigorous results showing that such separation might be possible – using special techniques. We are left with the situation of grounds for both hope and skepticism.

The idea to morphologically decompose a signal into its building blocks is an important problem in signal and image processing. An interesting and complicated image content separation problem is the one targeting decomposition of an image to texture and piece-wise-smooth (cartoon) parts. Since the pioneering contribution of the French mathematician Yves Meyer [9], we have witnessed a flurry of research activity in this application field. Successful methods for signal or image separation can be applied in a broad range of areas in science and technology including biomedical engineering, medical imaging, speech processing, astronomical imaging, remote sensing, communication systems, etc.

In [1], [2] a novel decomposition method – Morphological Component Analysis (MCA) – based on sparse representation of signals. MCA assumes that each signal is the linear mixture of several layers, the so-called Morphological Components, that are morphologically distinct, e.g. sines and bumps. The success of this method relies on the assumption that for every signal atomic behavior to be separated, there exists a dictionary of atoms that enables its construction using a sparse representation. It is then assumed that each morphological component is sparsely represented in a specific transform domain. And when all transforms (each one attached to a morphological component) are amalgamated in one dictionary, each one must lead to sparse representation over the part of the signal it is serving, while being highly inefficient in representing the other content in the mixture. If such dictionaries are identified, the use of a pursuit algorithm searching for the sparsest representation leads to the desired separation. MCA is capable of creating atomic sparse representations containing as a by-product a decoupling of the signal content. In [3], MCA has been extended to simultaneous texture and cartoon images inpainting. In [4], the authors formalized the inpainting problem

as a missing data estimation problem.

II. THEORY AND ALGORITHMS

Before describing of the MCALab library, let's first explain the terminology used throughout the paper, review the main theoretical concepts and give the gist of the algorithms.

A. Terminology

Atom: An atom is an elementary signal-representing template. Examples might include sinusoids, monomials, wavelets, Gaussians. Using a collection of atoms as building blocks, one can construct more complex waveforms by linear superposition.

Dictionary: A dictionary Φ is an indexed collection of atoms $(\phi_\gamma)_{\gamma \in \Gamma}$, where Γ is a countable set. The interpretation of the index γ depends on the dictionary; frequency for the Fourier dictionary (i.e. sinusoids), position for the Dirac dictionary (aka standard unit vector basis, or kronecker basis), position-scale for the wavelet dictionary, translation-duration-frequency for cosine packets, position-scale-orientation for the curvelet dictionary in two dimensions. In discrete-time finite-length signal processing, a dictionary can be viewed as a matrix whose columns are the atoms, and the atoms are considered as column vectors. When the dictionary has more columns than rows, it is called overcomplete or redundant. We are mainly interested here in overcomplete dictionaries. The overcomplete case is the setting where the signal $x = \Phi\alpha$ amounts to an underdetermined system of linear equations.

Analysis and synthesis: Given a dictionary, one has to distinguish between analysis and synthesis operations. Analysis is the operation which associates to each signal x a vector of coefficients α attached to atom: $\alpha = \Phi^T x$. Synthesis is the operation of reconstructing x by superposing atoms: $x = \Phi\alpha$. Analysis and synthesis are very different linear operations. In the overcomplete case, Φ is not invertible and the reconstruction is not unique; see also subsection II-B for further details.

Morphological component: For a given n -sample signal or image x , we assume that it consists of a sum of K signals or images $(x_k)_{k=1, \dots, K}$, $x = \sum_{k=1}^K x_k$, having different morphologies. Each x_k is called a morphological component.

Inpainting: Inpainting is to restore missing image information based upon the still available (observed) cues from destroyed, occluded or deliberately masked subregions of the signal or image. Roughly speaking, inpainting is an interpolation of missing or occluded data.

B. Fast implicit transforms and dictionaries

Owing to recent advances in modern harmonic analysis, many novel representations, including the wavelet transform, curvelet, contourlet, steerable or complex wavelet pyramids, were shown to be very effective in

sparsely representing certain kinds of signals and images. For decomposition purposes, the dictionary will be built by taking the union of one or several (sufficiently incoherent) transforms, generally each corresponding to an orthogonal basis or a tight frame.

From a practical point of view, given a signal x , we will need to compute its forward (or analysis) transform by multiplying it by Φ^T . We also need to reconstruct any signal from its coefficients α . In fact, the matrix Φ and its adjoint Φ^T corresponding to each transform are never explicitly constructed in memory. Rather they are implemented as fast implicit analysis and synthesis operators taking a signal vector x , and returning $\Phi^T x = \mathbf{T}x$ (e.g. Fourier or wavelet transforms), or taking a coefficient vector α and returning $\Phi\alpha$ (e.g. inverse Fourier or wavelet transforms).

C. Signal and Image decomposition

Suppose that the n -sample signal or image x is the linear superposition of K morphological components. The MCA framework aims at recovering the components $(x_k)_{k=1, \dots, K}$ from their observed linear mixture as illustrated by Fig. 1. This is obviously an ill-posed inverse problem. MCA assumes that a dictionary can be built by amalgamating several transforms (Φ_1, \dots, Φ_K) such that, for each k , the representation α_k of x_k in Φ_k is sparse and not, or at least not as sparse, in other $\Phi_l, l \neq k$. In other words, the sub-dictionaries (Φ_1, \dots, Φ_K) must be mutually incoherent. Thus, the dictionary Φ_k plays a role of a discriminant between content types, preferring the component x_k over the other parts.

Choosing an appropriate dictionary is then a key step towards a good sparse decomposition and inpainting. Thus, to represent efficiently isotropic structures, a qualifying choice is the wavelet transform [10]. The curvelet system [11] is a very good candidate for representing piecewise smooth (C^2) images away from C^2 contours. The ridgelet transform [12] has been shown to be very effective for representing global lines in an image. The local DCT (discrete cosine transform) [10] is well suited to represent locally stationary textures. These transforms are also computationally tractable particularly in large-scale applications, and as stated above, never explicitly implement Φ and \mathbf{T} . The associated implicit fast analysis and synthesis operators have typical complexities of $O(n)$, with n the number of samples or pixels (e.g. orthogonal or bi-orthogonal wavelet transform) or $O(n \log n)$ (e.g. ridgelet, curvelet, local DCT transforms).

By definition, the augmented dictionary $\Phi = [\Phi_1 \dots \Phi_K]$ will provide an overcomplete representation of x . Again, because there are more unknowns than equations, the system $x = \Phi\alpha$ is underdetermined. Sparsity can be used to find a unique solution, in some idealized cases; see the comprehensive review paper [13]. In [1], [2], it was proposed to solve this underdetermined system of equations and estimate the morphological components $(x_k)_{k=1, \dots, K}$ by solving the following constrained optimization problem:

$$\min_{x_1, \dots, x_K} \sum_{k=1}^K \|\Phi_k^T x_k\|_p^p, \text{ such that } \left\| x - \sum_{k=1}^K x_k \right\|_2 \leq \sigma, \quad (1)$$

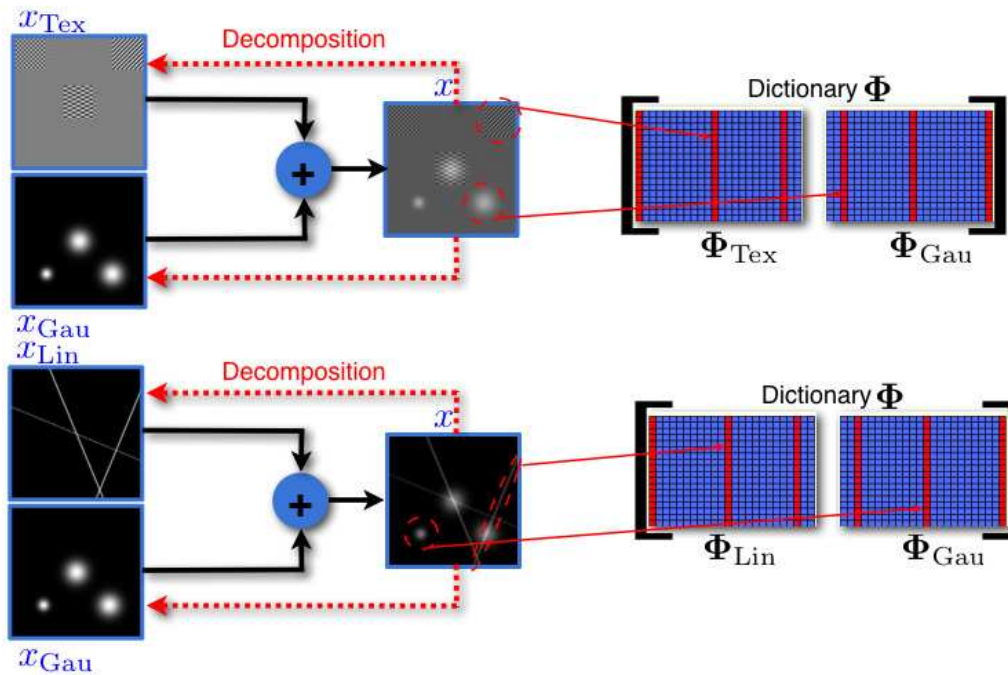

Fig. 1. Illustration of the image decomposition problem with sparse representations.

where $\|\alpha\|_p^p = \sum_i |\alpha(i)|^p$ is the penalty quantifying sparsity (the most interesting regime is for $0 \leq p \leq 1$), and $\|\alpha\|_0 = \lim_{p \rightarrow 0} \|\alpha\|_p^p$ is the ℓ_0 pseudo-norm, i.e. the number of nonzero components. The constraint in this optimization problem accounts for the presence of noise and model imperfection. If there is no noise and the linear superposition model is exact ($\sigma = 0$), an equality constraint can be substituted for the inequality constraint. This formulation is flexible enough to incorporate external forces that direct the morphological components to better suite their expected content, these forces will fine tune the separation process to achieve its task. As an example for such successful external force, [1] proposed to add a Total Variation (TV) penalty to the cartoon part in order to direct this component to fit the piecewise-smooth model. This leads to

$$\min_{x_1, \dots, x_K} \sum_{k=1}^K \|\Phi_k^T x_k\|_p^p + \gamma \|x_s\|_{\text{TV}}, \text{ such that } \left\| x - \sum_{k=1}^K x_k \right\|_2 \leq \sigma, \quad (2)$$

where s indexes the piecewise-smooth (cartoon) part, and γ the TV regularization parameter.

For the sake of completeness, the MCA algorithm proposed in [1] is summarized in Algorithm 1 below. It relies on an iterative thresholding scheme with varying threshold. In Algorithm 1, $\text{TH}_\lambda(\alpha)$ denotes component-wise thresholding with threshold λ , hard thresholding ($p = 0$ in (2)) or soft-thresholding ($p = 1$ in (2)). As far as the thresholding decreasing strategy is concerned, there are several alternatives. For example, in [1], [2], linear and exponential decrease were advocated. In [14], a more elaborated strategy coined MOM (for mean-of-max) was proposed. In this paper and version 1.1.0 of MCALab toolbox, only linear and exponential

decrease are implemented.

Algorithm 1 MCA component separation algorithm.

Task: Signal/image decomposition, solve (2).

Parameters: The signal/image x , the dictionary $\Phi = [\Phi_1 \cdots \Phi_K]$, number of iterations N_{iter} , γ and index of the cartoon part, stopping threshold λ_{\min} , threshold update schedule.

Initialization:

- Initial solution $x_k^{(0)} = 0, \forall k$.
- Initial residual $r^{(0)} = x$.
- Initial threshold: let $k^* = \max_k \|\Phi_k^T x\|_\infty$, set $\lambda^{(0)} = \max_{k \neq k^*} \|\Phi_k^T x\|_\infty$.

Main iteration:

For $t = 1$ **to** N_{iter}

- **For** $k = 1$ **to** K ,
 - Compute marginal residuals $r_k^{(t)} = r^{(t)} + x_k$.
 - Update k -th component coefficients by thresholding $\alpha_k^{(t)} = \text{TH}_{\lambda^{(t)}} \left(\Phi_k^T r_k^{(t)} \right)$.
 - Update k -th component $x_k^{(t)} = \Phi_k \alpha_k^{(t)}$.
 - If k is the cartoon part and $\gamma \neq 0$, apply TV penalty to $x_k^{(t)}$.
- Update the residuals $r^{(t+1)} = x - \sum_{k=1}^K x_k^{(t)}$.
- Update the threshold $\lambda^{(t+1)}$ according to the given schedule.
- **If** $\lambda^{(t+1)} \leq \lambda_{\min}$ **then** stop.

End iteration

Output: Morphological components $\left(x_k^{(N_{\text{iter}})} \right)_{k=1, \dots, K}$.

As suggested in [1], an approximation of the TV regularization is implemented in MCALab by soft-thresholding the undecimated Haar wavelet coefficients with threshold γ .

a) *Handling bounded noise:* MCA handles in a natural way data perturbed by additive noise ε with bounded variance $\sigma_\varepsilon^2 = \text{Var}[\varepsilon] < +\infty$. MCA is an iterative coarse-to-fine (in terms of coefficient amplitude in the dictionary) procedure and bounded noise can be handled just by stopping iterating when the residual is at the noise level. Assuming that the noise variance σ_ε^2 is known, the algorithm may be stopped at iteration t when the ℓ_2 -norm of the residual satisfies $\|r^{(t)}\|_2 \leq \sqrt{n}\sigma_\varepsilon$. Alternatively, one may use a strategy reminiscent of denoising methods, by taking $\lambda_{\min} = \tau\sigma_\varepsilon$ where τ is a constant, typically between 3 and 4.

D. Signal and Image inpainting

Let the original signal/image be defined on a bounded domain Ω . Suppose we partially observe a signal/image x on a compact domain $\Omega_o \subset \Omega$, $n_o = \text{Card}(\Omega_o)$, where some samples are missing (those indexed by $\Omega \setminus \Omega_o$). By "mask" \mathbf{M} we mean the diagonal $n \times n$ matrix where the observed samples are indicated by ones and the missing ones by zeros.

1) *Algorithm of Elad et al. [3]:* In [3], the authors describe an inpainting algorithm which is a direct extension of MCA that is capable of filling in holes in images that are superposition of a texture and cartoon

layers. Thus, (2) can be extended to incorporate missing data through the mask \mathbf{M} by minimizing

$$\min_{x_1, \dots, x_K} \sum_{k=1}^K \|\Phi_k^T x_k\|_p^p + \gamma \|x_s\|_{\text{TV}}, \text{ such that } \left\| x - \mathbf{M} \sum_{k=1}^K x_k \right\|_2 \leq \sigma. \quad (3)$$

In our approach to solving this optimization problem, we only need to adapt slightly the MCA Algorithm 1, modifying the residual update rule to $r^{(t+1)} = x - \mathbf{M} \sum_{k=1}^K x_k^{(t)}$ to account for the masking matrix \mathbf{M} . The other steps of the algorithm remain unchanged. See [3] for more details.

2) *Algorithm of Fadili et al. [4]*: When taking $p = 1$ and the TV-regularization term is dropped in (3), Fadili et al. [4] formalized the inpainting problem as a missing data estimation problem. They formulated the problem as a maximum penalized likelihood estimator with missing data and sparsity-promoting penalties. They carefully characterized it and solved it using tools from non-smooth convex optimization theory. A chief advantage of this algorithm is its ability to estimate the noise variance. Let's denote the relaxation parameter $0 < \mu < 2/(\sum_k \|\Phi_k\|_2^2)$, where $\|\Phi_k\|_2^2$ corresponds to the largest frame bound associated to Φ_k . For a self-contained exposition, the main inpainting method of [4] is summarized in Algorithm 2 below.

Algorithm 2 EM-inspired inpainting algorithm.

Task: Signal/image inpainting.

Parameters: Observed masked image x , the mask \mathbf{M} , the dictionary $\Phi = [\Phi_1 \dots \Phi_K]$, regularization parameter λ , initial $\sigma_\varepsilon^{(0)}$, convergence tolerance δ .

Initialization: Initial solution $\alpha_k^{(0)} = 0, \forall k$.

Main iteration:

Repeat

- Update the residual $r^{(t)} = x - \mathbf{M}\Phi\alpha^{(t)}$.
- Update the coefficients $\alpha^{(t)}$

$$\alpha^{(t+1)} = \text{SoftThreshold}_{\lambda\mu} \left(\alpha^{(t)} + \mu\Phi^T r^{(t)} \right).$$

- If desired, update $\sigma_\varepsilon^{2(t+1)}$ according to

$$\sigma_\varepsilon^{2(t+1)} = \frac{1}{n} \left[\sum_{i \in \Omega_o} \left(x(i) - (\Phi\alpha^{(t)})(i) \right)^2 + (n - n_o)\sigma_\varepsilon^{2(t)} \right].$$

Until $\|\alpha^{(t+1)} - \alpha^{(t)}\|_2 \leq \delta$.

Output: Inpainted image $\hat{x} = \Phi\alpha^{(t)} = \sum_k \Phi_k \alpha_k^{(t)}$.

Other variants are described in [4] and the interested reader may refer to that paper for further details.

Let's conclude this subsection by noting some differences and similarities between the above two inpainting algorithms:

- **Target:** in the formulation of [3], the targets are the morphological components x_k , component separation is a by-product of the inpainting process. While in [4] the problem is optimized with respect to the coefficients α_k . This distinction obviously disappears when Φ is an orthobasis.

- Parameters: in the MCA-based inpainting [3], the user provides the algorithm with a threshold-lowering schedule and a stopping threshold λ_{\min} , while in the second version [4], the user must give a fixed regularization parameter λ . In practice, it may be more difficult to choose λ than the stopping threshold.
- Noise: both algorithms handle the presence of noise. The second formulation is able to estimate the noise variance along with inpainting.
- Optimization algorithms: despite apparent similarities, the two formulations use different optimization frameworks. MCA is an heuristic algorithm, formed by hybridizing matching pursuit with block-coordinate relaxation. The formulation of [4] uses an iterative thresholding proximal iteration with a rigorous convergence analysis guaranteed when $p \geq 1$.

III. MCALAB ARCHITECTURE

A. The MCALab distribution

MCALab is a library of Matlab routines that implements the algorithms described here-above for signal/image decomposition and inpainting. The MCALab library provides the research community with open source tools for sparse decomposition and inpainting, and may be used to reproduce the figures in this paper and to redo those figures with variations in the parameters. The library is available free of charge over the Web at the address:

<http://www.morphologicaldiversity.org/mcalab.html>

The current version of MCALab is 1.1.0. It has been successfully tested under Unix Solaris/Linux/MACOSX PPC and Intel under Matlab 6.x and 7.x. MCALab is distributed under the CECILL license [15], so that advance permission is not required for non-commercial use.

The structure of the MCALab package is depicted in Fig. 2. MCALab has two main directories, one for 1D signals and the second for 2D images. Each of these directories has the same architecture and contains the following subdirectories:

- Dictionaries: A directory `MCALab110/xxx-D/Dictionaries` containing various fast implicit analysis and synthesis transforms including those discussed in subsection II-C.
- Decomposition: A directory `MCALab110/xxx-D/Decomposition` containing the implementation of Algorithms 1-2.
- Datasets: A directory `MCALab110/xxx-D/Datasets` containing signal and image datasets used to illustrate decomposition and inpainting. `MCALab110/One-D/Datasets` also contains a Matlab function that generates many artificial signals, and reads some real signals.
- DemoGUI: A directory `MCALab110/xxx-D/DemoGUI` containing a Graphical User-friendly Interface (GUI) to decompose and inpaint the user own data or data supplied with MCALab.

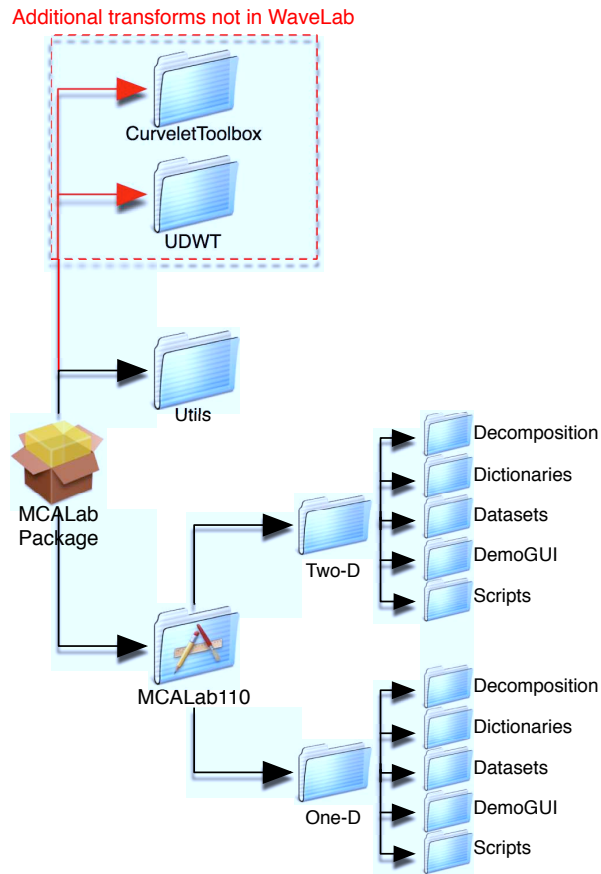

Fig. 2. MCALab package architecture.

- **Scripts:** A directory `MCALab110/xxx-D/Scripts` containing pedagogical examples with synthetic and real data that illustrate the use of MCA and inpainting algorithms. They also include examples of metadata structures that help reproducing the results and getting started with the package.

B. MCALab dependencies

As stated above, MCALab requires implementation of forward and inverse transforms. It turns out that many of them (orthogonal wavelet transform, discrete cosine and sine transforms, etc) are already implemented in WaveLab [16]. We then recommend that the users download and install WaveLab for MCALab to work properly.

For the user's convenience, MCALab also incorporates software for two other transforms not distributed with WaveLab. For instance the wrapping version of the Fast Discrete Curvelet Transform (FDCT) implemented in CurveLab [11], [17], and the undecimated discrete wavelet transform (UDWT) implemented in RWT [18]. Note that the FDCT Matlab functions `fdct_wrapping.m` and `ifdct_wrapping.m` (not the

Matlab Mex files) have been slightly modified to match our dictionary data structure, and to implement curvelets at the finest scale. We strongly recommend that the user downloads our modified version, or at least use our `fdct_wrapping.m` and `ifdct_wrapping.m`. Both of these transforms are available in a version of MCALab named `MCALabWithUtilities`; see dashed rectangle in Fig. 2. They are in the subdirectories `MCALabWithUtilities/CurveletToolbox` and `MCALabWithUtilities/UDWT`. The user may read `Contents.m` in `MCALabWithUtilities/` for further details. The user also is invited to read carefully the license agreement details of these transforms softwares on their respective websites prior to any use.

As MCALab has external library dependencies, this legitimately poses the problem of reproducibility and sensitivity to third-party libraries. However, the dependencies are essentially on the transforms, and given our implementation of the dictionaries (see section III-E), these transforms are called as external functions from MCALab. No modification is then necessary on the MCALab code if such transforms are corrected or modified. Moreover, to robustify the behavior of MCALab to these transforms, we have tested MCALab with both WaveLab 802 and 805, and CurveLab from version 1.0, 2.0, 2.1.1 and 2.1.2 and obtained exactly the same results.

C. MCALab metadata generation

MCALab also generates metadata that indicate many information that facilitate reproducibility and reusability. This metadata is generated as a Matlab structure object with fields indicating (see Fig. 3):

- The version of Matlab and machine architecture.
- The version of third-party libraries that were used for the generation of a given result. For example, in this paper we used WaveLab 802, CurveLab 2.1.1 and RWT 1.2.
- All the options from MCALab including its version (1.1.0 in this paper), the task (decomposition or inpainting), parameters, inputs/outputs and dictionary description.

When MCALab is launched upon call of `MCAPath.m`, this metadata object is initialized with Matlab version, machine architecture and external libraries versions. The object is then stored in the `Utils/` directory. The MCALab decomposition and inpainting routines load and add additional information to this object. Beside the resulting signals and images, the test scripts can either store this object or export it in HTML format using the MCALab function `metaoptions2html.m`, see the example of Fig. 3. Examples of metadata Matlab structure objects stored by the test scripts are available in the toolbox in the `.mat` Matlab format (version 5 for compatibility with older Matlab versions). Another interesting alternative that would be worth investigating in a future version would be to exploit the `XML Publish` function offered by Matlab but only available with versions 7.x and later.

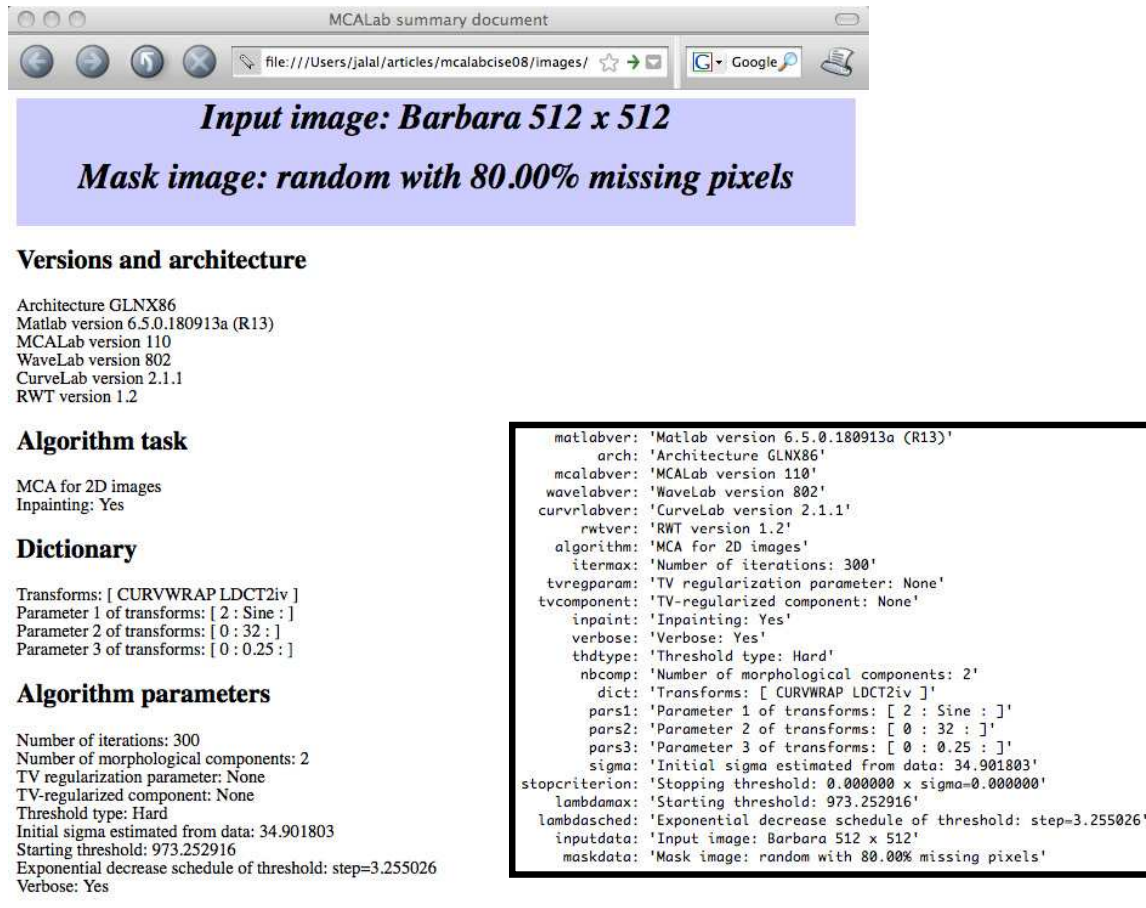

Fig. 3. Example of metadata generated by MCALab in HTML for the experiment of Fig. 10. The black rectangle represents the corresponding Matlab structure of metadata object.

To encourage users to reproduce our results from the metadata structure, we have also written an MCALab function `firefrommetadata.m` that is able to reproduce the results from metadata previously stored, together with as little extra information as possible. For the user convenience, MCALab includes two test scripts in `MCALab110/xxx-D/Scripts` that exemplify the use of `firefrommetadata.m` on some 1D and 2D examples.

D. Documentation

MCALab is documented and each function in MCALab has help documentation. The `README` and `INSTALL` files provide some guidelines which will help you access and install the software on your machine and get started in exploring the resources contained in the MCALab package. The reader may also look at the MCALab webpage which contains the following information: authors with links to their websites, abstract of this paper, full references of the papers MCALab is concerned with, a zipped archive of MCALab package, and an email

address for remarks and bug report. MCALab is under continuing development by the authors. We welcome your feedback and suggestions for further enhancements, and any contributions you might make.

E. Dictionaries and data structures

The functions in `xxx-D/Dictionary` subdirectory provide fast implicit analysis and synthesis operators for all dictionaries implemented in MCALab. It is worth noting that except for the FDCT with the wrapping implementation [11], all dictionaries provided in MCALab are normalized such that atoms have unit ℓ_2 -norm. The FDCT implements a non-normalized Parseval tight frame. Thus, a simple rule to compute the ℓ_2 -norm of the atoms is $1/\sqrt{\text{redundancy of the frame}}$. Normalization has an important impact on the thresholding step involved in the decomposition/inpainting engines. The thresholding functions coded in MCALab take care of these normalization issues for the dictionaries it implements.

The data structure as well as the routines are inspired from those of Atomizer [19]. The dictionaries are implemented in an object-oriented way. The top level routines are `FastLA` and `FastLS`. Each transform has a fast analysis and a fast synthesis function named respectively `FasNAMEOFTRANSFORMAnalysis` and `FasNAMEOFTRANSFORMSynthesis`. Four arguments (`NameOfDict`, `par1`, `par2`, `par3`) are used to specify a dictionary. The meaning of each parameter is explained in the corresponding routine. Each `FasNAMEOFTRANSFORMAnalysis` computes the transform coefficients (i.e. application of Φ^T) of an image or a signal and stores them in a structure array. We also define the `List` data structure and corresponding functions, which allow to create and easily manipulate overcomplete merged dictionaries. The interested user can easily implement its own dictionary associated to a new transform following the above development rules.

F. Decomposition and inpainting engines

The routines in this directory perform either signal/image decomposition and inpainting using the MCA-based Algorithm 1, or signal and image inpainting using Algorithm 2 described above. This set of routines are for dictionaries with fast implicit operators. They are also designed so as to return a metadata object that can be saved or exported in HTML format to facilitate result reproducibility.

G. Scripts and GUI

The makeup of `/MCALab110/xxx-D/Scripts` and `/MCALab110/xxx-D/DemoGUI` is the whole *raison d'être* of the MCALab toolbox. The subdirectory `/MCALab110/xxx-D/Scripts` contains a variety of scripts, each of which contains a sequence of commands, datasets and parameters generating some figures in our own articles, as well as other exploratory examples not included in the papers. One can also run the same experiments on his own data or tune the parameters by simply modifying the scripts. By studying these

scripts one can quickly learn the practical aspects of sparse-representation-based image decomposition and inpainting, and one can learn how to use the MCALab software library.

The routines in `/MCALab110/xxx-D/DemoGUI` implement a point-and-click GUI that allows the user to select data and masks (signals or images), and then decompose or inpaint them using MCA Algorithm 1. Only signals and images with two morphological components, hence two dictionaries, can be processed with this GUI. It is possible to select the type of dictionaries and their associated parameters `par1`, `par2`, `par3` for each morphological component. The main window is invoked via the command `MCA1Demo` (signals) or `MCA2Demo` (images). Upon initialization, one main window will appear with four plots, a menu and an interactive area on the right. Two additional pull-down menus on the top-bar are specific to MCALab GUI. They allow to load data variables from the Matlab workspace. Thus, prior to using the GUI, the signals, images or masks of interest must be first read from disk and loaded to the workspace using any Matlab input data reading routine. Note that if your goal is to decompose and not to inpaint, it is sufficient to create a dummy variable of ones of the same size as the data. By default, the GUI assumes the trivial mask (all ones).

IV. REPRODUCIBLE EXPERIMENTS

Data description, dictionaries and algorithm parameters used in the experiments of this section are summarized in Table I and Table II.

A. 1D examples

1) *Bumps + Local cosines*: The synthetic signal of Fig. 4(a) (dashed line) is a composite of two Gaussian bumps with different scales and two local cosine waves. In this synthetic signal, we know the ground truth decomposition. We also added white Gaussian noise with $\sigma_\epsilon = 0.429$ (PSNR=20dB). Based on the morphological content of this signal, we decomposed and denoised it using an overcomplete dictionary containing the local DCT and the undecimated wavelet transform (see Table I for the dictionary details). The standard deviation σ_ϵ was not supplied but estimated from the noisy data by the algorithm using the MAD estimator [20].

The results are displayed in Fig. 4(b)-(d). In (c) (resp. (d)) we can see the original (dashed line) and recovered (solid line) locally oscillating part (resp. localized bumps) recovered by MCA. The co-addition of both recovered components is plotted with a continuous line in Fig. 4(b) superimposed on the original signal (dashed line).

2) *TwinSine + Diracs*: The synthetic signal of Fig. 5(a) (dashed line) consists of three randomly located spikes and the TwinSine signal: two cosines with frequencies separated by less than the Rayleigh Distance. The TwinSine appears in [21]. We analyzed this signal with an overcomplete dictionary formed by merging a four-fold overcomplete DCT and a standard (Dirac) basis. The parameters chosen for this experiment are

Fig. 4. Decomposing and denoising Local sines + Bumps signal. See Table I for the experiment details.

summarized in Table I. The results are shown in Fig. 5(b)-(d). MCA managed to resolve the frequencies of the oscillating (TwinSine (b)-(c)) component and to separate it properly from the spikes shown in (d). Although some spurious frequencies are still present in the oscillating part. The locations of the true frequencies correspond to the dotted lines in Fig. 5(c), and the original spikes are indicated by the crosses in Fig. 5(d).

3) *EEG-fMRI*: MCA was also applied to a real signal acquired during a multi-modal neuroimaging experiment. During such an experiment, electroencephalography (EEG) and functional magnetic resonance imaging (fMRI) data are recorded synchronously for the study of the spatio-temporal dynamics of the brain activity. However, this simultaneous acquisition of EEG and fMRI data faces a major difficulty because of currents induced by the MR magnetic fields yielding strong artifacts that generally dominate the useful EEG signal. In a continuous acquisition protocol, both modalities are able to record data. But a post-processing step for EEG artifact reduction is necessary for the EEG signal to be exploitable.

An example of such a signal¹ is depicted in in Fig. 6(a). The periods where the MR sequence is switched on are clearly visible inducing strong oscillations on the EEG signal with an amplitude 10 to 20 times higher than the expected EEG amplitude. This locally oscillating behavior is expected because of the shape of the magnetic field gradients of the MR scanner. Therefore, to get rid off of the MR component and clean the EEG signal from these artifacts, we decomposed it using an overcomplete dictionary of local DCT (for the MR

EXPERIMENTAL SETUP FOR THE 1D EXAMPLES.

part) and the UDWT (for the EEG smooth and localized component). The parameters of this experiment are detailed in Table I. The results are displayed in Fig. 6(c)-(d). As a by-product, the signal was also cleaned from measurement noise.

B. 2D examples

1) Decomposition:

Boy + Texture: In this experiment, we generated a synthetic image composed of a natural scene and a texture, where we have the ground truth parts to compare against. This image was also used in [1], [3]. We

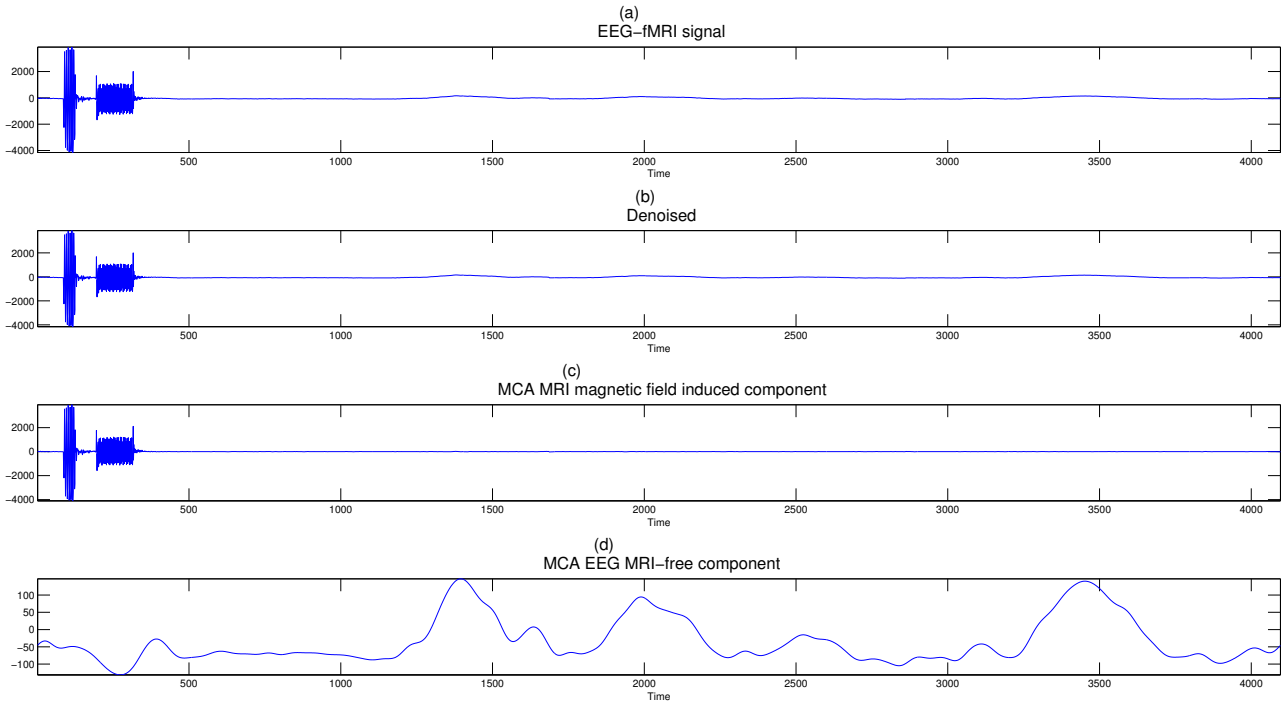

Fig. 6. Decomposing and denoising the EEG-MRI real signal. See Table I for the experiment details.

Image	Dictionaries	Task	Algorithm parameters
Boy + Texture 256 × 256	Curvelets (cartoon) (coarsest scale 2) Global DCT (texture) (low-frequencies removed)	Decomposition (Alg. 1)	$N_{\text{iter}} = 50$, $\gamma = 0.1$ (TV on cartoon part), $\lambda_{\text{min}} = 0$, exponentially decreasing threshold.
Barbara 512 × 512	Curvelets (cartoon) (coarsest scale 2) Local DCT (texture) (sine-bell window, width=32, low-frequencies removed)	Decomposition (Alg. 1)	$N_{\text{iter}} = 300$, $\gamma = 2$ (TV on cartoon part), $\lambda_{\text{min}} = 0$, exponentially decreasing threshold.
		Inpainting (Alg. 1-sec.II-D.1)	$N_{\text{iter}} = 300$, $\gamma = 0$ (no TV), $\lambda_{\text{min}} = 0$, linearly decreasing threshold
Risers 150 × 501	Curvelets (lines) (coarsest scale 2) UDWT (smooth and isotropic) (Symmlet 6, coarsest scale 2)	Decomposition and denoising (Alg. 1)	$N_{\text{iter}} = 30$, σ_{ε} : estimated from data, $\gamma = 2$ (TV on UDWT part), $\lambda_{\text{min}} = 3\hat{\sigma}_{\varepsilon}$, exponentially decreasing threshold.
Lines + Gaussians 256 × 256	Curvelets (lines) (coarsest scale 3) UDWT (Gaussians) (Symmlet 6, coarsest scale 2)	Inpainting (Alg. 1-sec.II-D.1)	$N_{\text{iter}} = 50$, $\gamma = 0$ (no TV), $\lambda_{\text{min}} = 0$, linearly decreasing threshold.
		Inpainting (Alg. 2-sec.II-D.2)	no noise, $\delta = 1\text{E-}6$, $\lambda = 0.3$.
Lena 512 × 512	Curvelets (coarsest scale 2)	Inpainting (Alg. 1-sec.II-D.1)	$N_{\text{iter}} = 300$, $\gamma = 0$ (no TV), $\lambda_{\text{min}} = 0$, exponentially decreasing threshold.
		Inpainting (Alg. 2-sec.II-D.2)	no noise, $\delta = 1\text{E-}6$, $\lambda = 10$.

TABLE II
EXPERIMENTAL SETUP FOR THE 2D EXAMPLES.

used the MCA decomposition Algorithm 1 with the curvelet transform for the natural scene part, and a global DCT transform for the texture; see Table II for details. The TV regularization parameter γ was fixed to 0.1. In this example as for the example of Barbara to be described hereafter, we got better results if the very low-frequencies were ignored in the textured part. The reason for this is the evident coherence between the two dictionaries elements at low frequencies - both consider the low-frequency content as theirs. Fig. 7 shows the original image (addition of the texture and the natural parts), the reconstructed cartoon (natural) component and the texture part.

Barbara: We have also applied the MCA decomposition Algorithm 1 to the Barbara image. We used the curvelet transform for the cartoon part, and a local DCT transform with a smooth sine window and a window size 32×32 for the locally oscillating texture. The TV regularization parameter γ was set to 2. Fig. 8 displays the Barbara image, the recovered cartoon component and the reconstructed texture component.

Risers: The goal of this experiment is to illustrate the usefulness of MCA in a real-life application such as studying the mechanical properties of composite risers used in the oil industry [22]. The top image of Fig. 9 displays a riser made of many layers that was recorded using a digital X-ray camera [22]. The riser is made of a composite material layer, a layer of steel-made fibers having opposite lay angles, and lead-made markers used as a reference to calibrate the X-ray camera. The structures of interest are the curvilinear fibers. But, the markers that appear as black isotropic structures on the image, hide the fiber structures that exist behind them. Our goal is to decompose this X-ray image into two components: one containing the curvilinear fiber structures and the other with the lead-made markers and the smooth background. Therefore, natural candidate dictionaries would be the curvelet transform for the fibers, and the UDWT for the isotropic markers and the piecewise smooth background component. The TV penalty will be added to direct the image with the lead markers to fit the piecewise smooth model with $\gamma = 3$. The image was also denoised by setting $\lambda_{\min} = 3\sigma_{\epsilon}$. Fig. 9 illustrates the separation provided by the MCA. The top row depicts the original image, the middle and bottom rows give the two components recovered by MCA. One can clearly see how it managed to get rid of the lead-made markers while preserving the curvilinear fibers structure, and even reconstructing the unobserved fibers parts that were behind the markers.

2) *Inpainting:*

Barbara: Fig. 10 shows the Barbara image and its inpainted results for three random masks of 20%, 50%, and 80% missing pixels. The unstructured random form of the mask makes the recovery task easier which is intuitively acceptable using a compressed sensing argument [23], [24]. Again, the dictionary contained the curvelet and local DCT transforms. The algorithm is not only able to recover the geometric part (cartoon), but particularly performs well inside the textured areas.

Lines + Gaussians: We applied the two inpainting algorithms given in Algorithm 1-Section II-D.1 and Algorithm 2-Section II-D.2 to a synthetic image which is a composite of three Gaussians and three lines, see

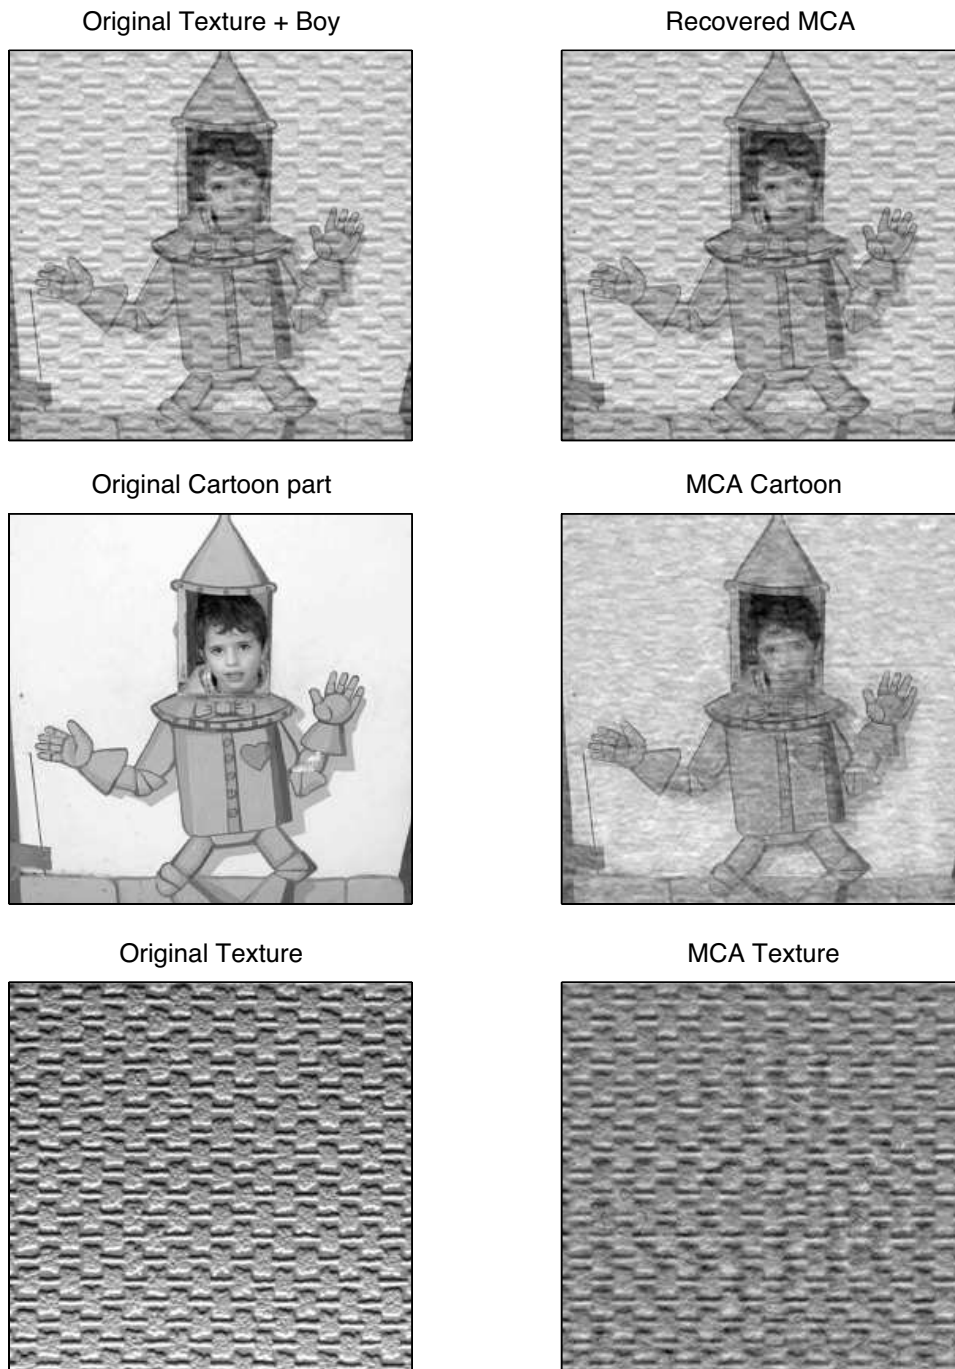

Fig. 7. Decomposing Boy-Texture image. See Table II for the experiment details.

Fig. 8. Decomposing Barbara image. See Table II for the experiment details.

Fig. 11 top-left. Based on this morphological content, the UDWT and the curvelet transforms were chosen as candidate dictionaries. The parameters chosen for each algorithm are summarized in Table II. The masked and filled-in images are portrayed in Fig. 11. Both inpainting algorithm performed well, although the result of Algorithm 2 is somewhat smoother.

Lena: We repeated the same experiment with Lena 512×512 . The masked image is depicted in Fig. 12 top-right, where 80% pixels were missing, with large gaps. The dictionary contained the curvelet transform. The parameters chosen for each algorithm are given in Table II. Despite the challenging difficulty of this example (large gaps), both inpainting algorithms performed well. They managed to recover most important details of the image that are hardly distinguishable by eye in the masked image. The visual quality is confirmed by measures of the PSNR as reported in Fig. 12.

Fig. 9. Decomposing Risers image. See Table II for the experiment details.

V. CONCLUSION AND FUTURE DIRECTIONS

Reproducible computational research remains an exception rather than a common practice in most published papers of the image and signal processing community. In this paper, we described our experience of reproducible research with MCALab, a complete software environment for sparse-representation-based signal/image decomposition and inpainting. We described its architecture and discussed some results that can be reproduced by running corresponding scripts in the MCALab package. Other exploratory examples not included in the paper as well as a graphical user interface are also included in MCALab. We have also recently released a C++ batch version of MCALab. It is available for download from the first author's webpage. The MCALab is under continuing development by the authors. Constructive feedback, suggestions and contributions are warmly welcomed.
