Keywords. Petri nets Bonds Calculus of covalent bonding Natural computing

### ABSTRACT

In nature and chemistry the interactions among elements often form bonds and among them covalent bonds are relevant, involving the sharing of electrons. Another relevant and compelling facet of calculi modelling covalent bonds is that certain steps in reactions are the result of concerting different activities, possibly reversing some of them. Starting from a calculus for covalent bonds, we investigate on how it can be done in a compositional fashion and how it can be encoded in suitable Petri nets. The outcome gives us a compositional covalent bond calculus and a truly distributed implementation. On these results it is possible to build a behavioural equivalence among terms.

### 1. Introduction

The study of biochemical reactions as computational processes started with the seminal paper of the Chemical Abstract Machine (CHAM) [1]. In the sequel, several formal languages tailored to the modelling of biochemical reactions have been proposed in the literature [2–9]. Typically, those languages allow for the description of processes concerning the formation of chemical bonds, i.e., the linkage between atoms, molecules and ions that produce chemical compounds. As an example, consider the catalysed reaction for the hydration of formaldehyde in water depicted in Fig. 1 in which two molecules A and B bond together via a catalyser C. Firstly, each of the molecules A and B bonds with the catalyser C (depicted as arcs labelled by c and d). After that, A and B bond together (arc labelled by q) and, at the same, the existing bond c is broken. Finally, the bond d between B and C is broken; which releases C for serving as catalyser for another reaction.

In computational terms, the transformations in Fig. 1 can be thought of as different nature: the first one creates bonds, the last one undoes a previously created bond, and the second one mixes the creation of a new bond with the undoing of a previously created bond. Hence, the underlying computational model can be seen as a reversible model, i.e., one that features two flows of execution: a forward (normal) one and a backward one that undoes the effects of previously executed actions. Some models for biochemical processes are built upon this observation [10,8]. In this paper we focus on the Calculus of Covalent Bonding (CCB) [8], which embodies a reversible model with very distinctive features. Differently from most of the reversible process calculi in the literature [11–14], a computation step in CCB may combine forward and backward flows: Thanks to the so called concerted actions, a single reduction step in CCB can simultaneously create a bond and break an existing one, akin to the second transformation in Fig. 1. Moreover, CCB enjoys some form of out-of-causal order reversibility [15], i.e., a process may exploit backward computation to reach states that cannot be reached by relying only on forward computation. As an example, consider the scenario introduced in Fig. 1 and assume that A and B cannot bond

Fig. 1. A catalytic reaction (borrowed from [8]).

together without the participation of C. Consequently, the final state in Fig. 1 is only reachable because of the undoing of some previous forward steps (i.e., the breaking of the bonds *c* and *d* created in first step).

Interestingly, the distinguishing features of CCB are obtained via some not-so-standard ingredients in the operational semantics of the language; namely, the lookahead mechanism for concerted actions and the need of assigning priority to the reductions that exchange bonds within prefixes. Consequently, it becomes natural to ask whether the essential features of CCB can be explained by recasting to standard computational models. In this paper we provide an affirmative answer to that question by exploiting some recent results that show that Petri nets with inhibitor arcs can provide a unifying presentation for different reversible models [16-18]. As a by-product, our study sheds lights about some interesting aspects in the definition of CCB as, for instance, the fact that its semantics is non-compositional, and that it allows for the formation of bonds among an unbounded number of components.

Concretely, we introduce a variant of CCB that retains the intuitions, motivations and most of the capabilities of the original calculus, but has compositional semantics and avoids lookahead and priorities. For technical simplicity, we restrict our analysis to the fragment of binary bonds, i.e., we consider synchronisation algebras that only allow for bonds formed between exactly two components. Despite this choice reduces the synchronisation capabilities of the calculus, we remark that all case studies in [8] lay within this fragment. 

Then, we show that each term of the calculus can be encoded into a behavioural equivalent (i.e., bisimilar) Petri net. Alike previous approaches aimed at expressing reversibility in Petri nets, our encoding needs to ensure that each marking of a net conveys sufficient information to enable exactly those admissible forward and backward computations, which is particularly challenging when dealing with out-of-causal order reversibility [19]. Here, we rely on [17] to accommodate out-of-causal order reversibility by representing causality in terms of inhibitor arcs. Another key ingredient of our encoding concerns the static representation of bonds, which are dynamically generated in CCB. We first note that bonds play the role of the communication keys present in some reversible calculi [11]. As done in [18], we represent dynamically generated communication keys with statically designated places of a net. This allows us to show that a proper subclass of Petri nets with inhibitor arcs, dubbed *covalent bond nets*, is expressive enough for encoding CCB terms, 

Besides showing that the essential features of CCB can be obtained without appealing to mechanisms such as the fresh generation of keys, lookahead of computation steps or prioritised reductions, our encoding paves the way for the application of consolidated analysis techniques that have been developed for Petri nets for decades. 

Our contribution is structured as follows: We introduce CCB and illustrates its applicability in Section 2; we revise the original semantics of CCB in Section 3 in order to have compositional semantics. After recalling the standard notion of Petri nets with inhibitor arcs (Section 4), we introduce covalent bond nets (CBN) (Section 5), which are a proper subclass of Petri nets with inhibitor arcs that corresponds to CCB terms. The encoding of CCB into CBN is presented in Section 6. The and finally state our main result in terms of an operational correspondence between the encoding and the compositional CCB. 

### Acknowledgement

This is our contribution to the Festschrift that celebrates Gabriel Ciobanu's 65th birthday. We tried to gather together just three, among many, topics in which Gabriel has been a pioneer, a prolific author and a great curious: models for biological systems (with a particular perspective on membrane systems) [20–22], reversibility [23–27] and Petri nets [28–30] just to cite a few of them.

Besides being an influential scientist, Gabriel has also been a mentor and a source of inspiration for many researchers. His curiosity and dedication to research will inspire generations. We hope it inspired us. Therefore we wish to thank Gabriel for being a friend and a guide for all of us. 

We thank the reviewers. Their useful suggestions and criticisms have helped us in improving the paper.

### Notation

We recall some useful notions that will be used throughout this paper.  $\mathbb N$  denotes the set of natural numbers. A *multiset* over a set A is a function  $m: A \to \mathbb{N}$ . A multiset m will be often written by listing its elements separated by a comma, for instance the multiset m such that m(a) = 2, m(b) = 1 and m(x) = 0 for any other  $x \in A$  different from a or b will be a, a, b. We assume multisets to be equipped with the usual operations of union (+) and difference (-), and write  $m \subseteq m'$ if m(a) < m'(a) for all  $a \in A$ . We often confuse a multiset m with the set  $\{a \in A \mid m(a) \neq 0\}$  when  $\forall a \in A.m(a) < 1$ . In such cases, we write  $a \in m$  instead of  $m(a) \neq 0$ , and  $m \subseteq A$  if m(a) = 1 implies  $a \in A$ . Furthermore, we will use standard operations on sets, such as  $\cap, \cup$  or  $\setminus$ . The set of all multisets over A is denoted by  $\mu A$ . The multiset m where for each 

 $\alpha ::= (r; b)$   $S ::= \alpha . S | \mathbf{0}$  $P ::= S | P || P | P \setminus L$ 

 $a \in A$  it holds that m(a) = 0 is the empty multiset and, with abuse of notation, we write  $\emptyset$  for it. As usual, given  $a \in A$ , we write a also for the singleton  $\{a\}$ .

## 2. The calculus of covalent bonding

In this section we report the finite part of the *Calculus of Covalent Bonding* [31,8], CCB for short. CCB is a reversible, concurrent calculus tailored to the modelling of biochemical reactions.

The set of CCB actions  $A = \{a, b, c, ...\}$  is partitioned into *strong* and *weak actions* that respectively belongs to S and W. In what follows we shall write some actions in *italics*, e.g., *a*, *b*, *c*, ..., to emphasise that they are weak. The syntax of finite CCB is in Fig. 2.

All operators but the shape of prefixes  $\alpha$  are standard. As usual, **0** represents the idle process,  $\alpha$ .S stands for a process prefixed by  $\alpha$ , and  $\mathbb{P} \parallel \mathbb{Q}$  represents the *parallel* composition of  $\mathbb{P}$  and  $\mathbb{Q}$ , i.e., the processes  $\mathbb{P}$  and  $\mathbb{Q}$  can either execute independently or synchronise with each other during computation. The *hiding* operator  $\mathbb{P} \setminus L$  controls the scope of actions in a process, i.e.,  $\mathbb{P} \setminus L$  behaves as  $\mathbb{P}$  except for the fact that it cannot perform any action belonging to the set of actions  $L \subseteq A$ .

A prefix (r; b) consists of a finite multiset of actions r and a weak action b, which are respectively called *strong* and *weak* (*part of the*) *prefix*. Intuitively, the optional weak action b becomes enabled only after all actions in r have been performed; the order in which actions in s are executed is irrelevant. It is assumed that r is not empty and at most one of its actions can be weak, i.e.,  $r \in \mathbb{N}^{\mathcal{A}} \cup \mathcal{W} - \emptyset$  and for all  $b, c \in \mathcal{W}$  if r(b) > 0 and r(c) > 0 then b = c and r(b) = 1. Additionally, b can sometimes be omitted, and we will write prefixes simply as (r).

**Example 1.** We now illustrate strong and weak prefixes. Suppose  $a, b \in S$  to be two strong actions and  $c \in W$  a weak one. Then, the prefix (a, b; c) is such that the multiset a, b is the strong (part of the) prefix and the action c is the weak (part of the) prefix. Intuitively, the actions in the strong prefix a, b can be performed in any order, while the weak prefix c can occur only after a and b. The prefix (a, b, c) has instead the multiset a, b, c as its strong part and its weak part has been omitted. In this case, the prefix does not impose any order on the execution of the actions: the weak action c in the strong prefix can be performed even before the strong actions a and b. The distinction between weak and strong actions concerns to the capability of moving bonds between actions, which will be made clear when presenting the semantics of the language.

A distinctive feature of the introduced prefixes (r; b) is that the execution of the weak prefix b forces the process to undo some previously executed action.

The reversibility mechanism of CCB is modelled via communication keys [11]. Let  $\mathcal{K} = \{k, l, m, n, ...\}$  be the set of communication keys. Then, the set of performed actions is defined as  $\mathcal{A} \times \mathcal{K}$ . Hereafter, we write a[k] for the performed action (a, k).

The runtime syntax of the calculus is obtained by extending prefixes as follows

$$\alpha ::= \ldots \mid (s; \beta)$$

with  $s \in \mathbb{N}^{(\mathcal{A} \times \mathcal{K}) \cup \mathcal{A}}$ . We let  $t, t', \ldots$  range over  $\mathbb{N}^{\mathcal{A} \times \mathcal{K}}$ ; and  $\beta, \beta'$  to range over  $\mathbb{N}^{(\mathcal{W} \times \mathcal{K}) \cup \mathcal{W}}$ .

Before defining the set of free names and bound names of a process, we need to define the set of names of a multiset possibly marked with keys. We indicate such a set with n(s) and we define it as follows:

$$n(\mathbf{a}, \mathbf{s}) = n(\mathbf{a}[k], \mathbf{s}) = \{\mathbf{a}\} \cup n(\mathbf{s}) \qquad n(\emptyset) = \emptyset$$

The set of *free names* and *bound names* of a process *P*, denoted respectively as fn(P) and bn(P), are inductively defined as follows

		51
$fn((s; \beta).\mathbb{P}) = n(s, \beta) \cup fn(\mathbb{P})$	$fn(\mathbb{P} \parallel \mathbb{Q}) = fn(\mathbb{P}) \cup fn(\mathbb{Q})$	52
$fn(\mathbb{P} \setminus L) = fn(\mathbb{P}) \setminus L$	$fn(0) = \emptyset$	53
$bn((s; \beta).P) = bn(P)$	$bn(\mathbb{P} \parallel \mathbb{Q}) = bn(\mathbb{P}) \cup bn(\mathbb{Q})$	54
$bn(\mathbf{P} \setminus L) = bn(\mathbf{P}) \cup L$	$bn(0) = \emptyset$	55
		56

The following notions are instrumental to the definition of the operational semantics of the calculus.

$$key(\emptyset) = \emptyset \qquad key(a[k], s') = \{k\} + key(s') \qquad key(a, s') = key(s')$$

### Fig. 3. Forward SOS rules.

The set of keys of a process  $\mathbb{P}$ , written  $key(\mathbb{P})$ , is inductively defined as follows:

(W-ACT1)  $\frac{std(S) \quad fresh(k, t)}{(t; b).S \stackrel{(b)[k]}{\longrightarrow} (t; b[k]).S}$ 

 $(PAR) \xrightarrow{P \xrightarrow{a[k]} P'} fresh(k, Q)$ 

 $key((s; \beta).P) = key(s, \beta) \cup key(P)$  $key(\mathbf{0}) = \emptyset$  $key(\mathbb{P} \setminus L) = key(\mathbb{P})$  $kev(\mathbb{P} \parallel \mathbb{O}) = kev(\mathbb{P}) \cup kev(\mathbb{O})$ 

**Definition 2.** A key k is fresh in a process P (resp., in a multiset of actions s) written fresh(k, P) (resp. fresh(k, s)) if  $k \cap$  $key(\mathbb{P}) = \emptyset$  (resp.,  $k \cap key(s) = \emptyset$ ).

Terms are considered up-to the structural congruence  $\equiv$ , i.e., the least congruence defined such that  $\parallel$  is associative and commutative with identity **0** and satisfies the following rule

$$\mathbb{P} \setminus L \parallel \mathbb{Q} \equiv (\mathbb{P} \parallel \mathbb{Q}) \setminus L \quad \text{if} \quad fn(\mathbb{Q}) \cap L = \emptyset$$

The operational semantics of the forward flow of the computation is defined by the inference rules in Fig. 3.

Rule ACT1 mimics forward rules of reversible calculi based on communication keys: if a prefix contains an unperformed action a, then such action is executed by assigning a fresh key k to it. The chosen key is reflected in the label a[k] and the continuation records that a has been already executed with key k. Rule ACT2 states that a computation can proceed under a prefix only when the multiset of actions in the prefix has been already executed (recall that  $t \in \mathbb{N}^{\mathcal{A} \times \mathcal{K}}$ ). Rule PAR accounts for the execution of a forward action by one of the processes in a parallel composition; this is possible only when the assigned key k has not been used in  $\bigcirc$ . The synchronisation of actions in concurrent processes is described by Rule com. The communication model follows ACP [32], in which a symmetric, binary, partial function  $\gamma : \mathcal{A} \times \mathcal{A} \to \mathcal{A}$  defines the allowed interactions, e.g., two actions a and b synchronise if and only if  $\gamma(a, b)$  is defined. Moreover, their interaction is described by the action  $\gamma(a, b)$ . Hence, the rule com states that two concurrent processes interact if: (i) they execute synchronisable actions according to  $\gamma$  and (ii) the processes agree on the communication key k assigned to the actions. Rule RES states that a process cannot perform a restricted action; this also includes the cases in which the restricted action is consequence of the synchronisation of two actions. For instance, the process  $((a; b).0 || (a; b).0 \setminus \{c\}$  is blocked if  $\gamma(a, a) = c$ . The two rules w-AUX1 and w-AUX2 describe the executions of weak prefixes. Rule w-AUX1 accounts for the execution of the weak prefix b, which is allowed only if the continuation P has not been started. The execution of the action b is associated with a fresh key (as for any action in a prefix), however the parenthesis in the label (i.e., (b) instead of b) reflects that b has been executed as part of a weak prefix. Rule AUX2 accounts for the execution of a weak prefix below a prefix, which is analogous to the rule ACT2. Note that the label (b) forbids the application of rule COM, hence synchronisations involving labels like (b) are prohibited.

Note that the operational rules allow for non-binary interactions. Consider  $(a; b).S_1 \parallel (a; b).S_2 \parallel (a; b).S_3$  and  $\gamma$  defined such that  $\gamma(a, a) = a$ . Then, a 3-way synchronisation is possible as shown below:

$std(S_1)$	$std(S_2)$	
$(a; b).S_1 \xrightarrow{a[k]} (a[k]; b).S_1$	$(a; b).S_2 \xrightarrow{a[k]} (a[k]; b).S_2$	std(S <sub>3</sub> )
$(a; b).S_1 \parallel (a; b).S_2 \xrightarrow{a[k]}$	$(a[k]; b).S_1 \parallel (a[k]; b).S_2$	$(a; b).\mathbb{S}_3 \xrightarrow{a[k]} (a[k]; b).\mathbb{S}_3$
$(a; b).\mathbb{S}_1 \parallel (a; b).\mathbb{S}_2 \parallel$	$(a; b).\mathbf{S}_3 \xrightarrow{a[k]} (a[k]; b).\mathbf{S}_1 \parallel (a[k]; b)$	$[k]; b).\mathbf{S}_2 \parallel (\mathbf{a}[k]; b).\mathbf{S}_3$

For technical simplicity in the following sections, we restrict our attention to binary synchronisations, i.e., hereafter we just consider synchronisation functions  $\gamma$  defined such that an action in the image of  $\gamma$  does not enable further synchronisations.

 $\forall a, b, c \in \mathcal{A}. \gamma(a, b) = c$  implies  $\forall d \in \mathcal{A}. \gamma(c, d)$  undefined

$$\operatorname{Fig. 5. Concerted SOS rules.}$$

<sup>2</sup> Despite our development does not depend on the following assumption, we will only consider synchronisation functions <sup>3</sup> such that  $dom(\gamma) \subseteq (W \times W) \cup (S \times S)$  to forbid mixed synchronisations between strong and weak actions. It should be <sup>5</sup> noted that the forward flow does not allow for synchronisation of a weak action *b* in a prefix of the form (t; b). Such <sup>6</sup> weak action will come to play in combination with the reversing mechanism of actions. To that aim, we assume that every <sup>7</sup> action a is associated with a reversing action <u>a</u> and write <u>A</u> for the set of reversible actions, i.e., <u>A</u> = {<u>a</u> |  $a \in A$ }. Then, a <sup>8</sup> backward/reversing step in a computation will be represented by a label of the form <u>A</u> ×  $\mathcal{K}$ , which will be written as <u>a</u>[k] <sup>9</sup> instead of (<u>a</u>, k). Backward transitions are given by the inference rules in Fig. 4. It should be notice that each forward rule <sup>1</sup> in Fig. 3 is paired with a backward version that undoes the computation step. The rules are self-explanatory. Differently <sup>1</sup> from the original presentation of CCB, we write rule <u>ACT1</u> to make explicit that it can be applied regardless of whether the <sup>2</sup> weak prefix has been already executed or not, i.e., we write  $\beta \in \{b, b[k]\}$  instead of just *b* (disallowing *b*[k] makes concerted <sup>3</sup> rules inapplicable as discussed in the following).

The characteristic feature of CCB concerns the execution of the weak prefix, which forces the reversing of an executed action of the same prefix. Such behaviour is described by the concert rules in Fig. 5. The interactions of a process through a weak prefix are given by rule CONCERT. On the one hand, the process P aiming at synchronising over a weak prefix should also reverse a previously executed action: the first premise accounts for the execution of the weak prefix (b) while the second one stands for the reversal of a. On the other hand, the remaining parallel component Q should execute a forward action that synchronises with b and reverse an action d that synchronises with a. Interestingly, Q can execute the matching forward action c that synchronises with b either as part of a strong prefix or as its weak prefix. For this reason, the third premise requires a reduction labelled by  $\alpha \in \{c, (c)\}$ . The label of a concerted action records both the forward synchronisation  $\gamma(b, c)$  and the reverse one  $\gamma(a, d)$ . Note that the premises of the rule CONCERT have a look-a-head mechanism, meaning that the right-end side of a premise may occur in the left-hand side of the premise [33]. If we look at the premises of the CONCERT we have that this is the case for P' and Q'. The remaining rules stand for the contextual cases for concerted transitions. 

It should be noted that there are no contextual rules for transitions corresponding to the execution of weak prefixes, e.g., we cannot derive  $P \parallel Q \xrightarrow{(b)[k]} P' \parallel Q$  from  $P \xrightarrow{(b)[k]} P'$ . Consequently, the first two premises in rule concert should be interpreted as requiring the same agent to execute the forward action (*b*) and the reverse one <u>a</u>. Moreover, the premises in ACT1 and <u>ACT1</u> imply that such actions corresponds to the same prefix. Contrastingly, the third and fourth premises in concert allow the forward action to be executed by some sequential agent, while the reverse action can be performed by other agent, as illustrated by the following derivation

$$\begin{array}{c} (a[l];b).\mathbf{0} \xrightarrow{(b)[k]} (a[l];b[k]).\mathbf{0} & (a[l];b[k]).\mathbf{0} \xrightarrow{\underline{a[l]}} (a;b[k]).\mathbf{0} \\ \hline (c;e).\mathbf{0} \parallel (d[l];e).\mathbf{0} \xrightarrow{c[k]} (c[k];e).\mathbf{0} \parallel (d[l];e).\mathbf{0} & (c[k];e).\mathbf{0} \parallel (d[l];e).\mathbf{0} \xrightarrow{\underline{d[l]}} (c[k];e).\mathbf{0} \parallel (d;e).\mathbf{0} \\ \hline (a[l];b).\mathbf{0} \parallel (c;e).\mathbf{0} \parallel (d[l];e).\mathbf{0} \xrightarrow{\{\gamma(b,c)[k],\gamma(a,d)[l]\}}} (a;b[k]).\mathbf{0} \parallel (c[k];e).\mathbf{0} \parallel (d;e).\mathbf{0} \end{array}$$

<sup>58</sup> in which the forward weak action synchronises the first and second agent while the reverse one synchronises the first and <sup>60</sup> the third one. In order to be able to apply rule CONCERT, it is essential to derive  $(a[l]; b[k]) \cdot \mathbf{0} \xrightarrow{\underline{a}[l]} (a; b[k]) \cdot \mathbf{0}$ , i.e., to be able <sup>61</sup> to apply <u>ACT1</u> also when the weak prefix corresponds to an already executed action.

(s, a; b[k]).  $\stackrel{\tau}{\rightarrow} (s, a[k]; b)$ .  $s a \in S$ PROM (s, a, b[k]; c).  $S \xrightarrow{\tau} (s, a[k], b; c)$ .  $S = a \in S$ Move

Fig. 6. Pre-congruence rules for the promotion of a weak bond.

We now are in place to model the example depicted in Fig. 1.

**Example 2.** Let A = (c; q), B = (d, q) and C = (c, d) the molecules of Fig. 1. For simplicity we omit the trailing **0**s. Supposing  $\gamma(c, c) = f$ ,  $\gamma(d, d) = e$  and  $\gamma(q, q) = a$ , we can derive the following synchronisations:

$$A \parallel B \parallel C \xrightarrow{f[1]} (c[1];q) \parallel B \parallel (c[1],d) \xrightarrow{e[2]} (c[1];q) \parallel (d[2],q) \parallel (c[1],d[2])$$

Thanks to a concerted action, the process (c[1]; q) may break (i.e., undo) the bond on c and create a bond on q. We have:

 $(c[1]; q) \parallel (d[2], q) \parallel (c[1], d[2]) \xrightarrow{\{a[3], \underline{f}[1]\}} (c; q[3]) \parallel (d[2], q[3]) \parallel (c, d[2])$ 

We remark that the above transition cannot be derived with the original semantics of CCB [8], because the rule ACT1 requires the weak prefix to be a non-executed action (as discussed in the description of rule CONCERT).

Finally, the bond on *d* can be break and *C* gets free, i.e.,

$$(\mathsf{c};q[3]) \parallel (\mathsf{d}[2],q[3]) \parallel (\mathsf{c},\mathsf{d}[2]) \xrightarrow{\mathsf{e}[2]} (\mathsf{c};q[3]) \parallel (\mathsf{d},q[3]) \parallel (\mathsf{c},\mathsf{d})$$

We remark that there are no reverse rules for weak prefixes. However, a bond on a weak action is aimed at modelling a weak bond in a chemical reaction, which should be interpreted as a temporary bond that should be "passed" to a strong action as soon as possible to release the bond on the weak action, *committing* it. This is modelled in CCB via the rules in Fig. 6. The transitions are labelled with  $\tau$ , which stands for internal, silent moves. Rule PROM deals with the transfer of the key from the weak prefix to some strong action a that has not been executed yet. Rule Move transfers a key from a weak action in a strong prefix to some strong action a that has not been executed yet. Also here our presentation deviates from the original one, since MOVE allows to transfer a key only in absence of a weak prefix. For uniformity in the presentation, we assume all prefixes to carry its strong and weak components. Then, a process like (s). P in the original presentation, which does not provide a synchronisation via a weak prefix can be written simple as  $((s; b).P) \setminus b$  for some b not appearing in P. According to [8], pre-congruence rules have priority over the transition rules. That is, they has to be applied as soon as possible.

As previously discussed, the operational semantics is defined up-to structural congruence of terms, formally, by the following rule:

STRUCT 
$$\frac{P \equiv P' \quad P' \stackrel{\mu}{\rightarrow} Q' \quad Q' \equiv Q}{P \stackrel{\mu}{\rightarrow} Q}$$

We now show an example of how rules in Fig. 6 can be used.

**Example 3.** Consider the process  $(a; b) \parallel a \parallel b$  with  $\gamma(a, a) = c$  and  $\gamma(b, b) = d$ . We have the following reduction:

$$(\mathbf{a}; b) \parallel \mathbf{a} \parallel b \xrightarrow{\mathbf{c}[1]} (\mathbf{a}[1]; b) \parallel \mathbf{a}[1] \parallel b \xrightarrow{\{d[2], \underline{c}[1]\}} (\mathbf{a}; b[2]) \parallel \mathbf{a} \parallel b[2]$$

Now, the weak bond on b in process  $(a; b[2]) \parallel a \parallel b[2]$  can be promoted to a strong bond; this is achieved by applying rule PROM as follows:

 $(a; b[2]) \parallel a \parallel b[2] \xrightarrow{\tau} (a[2]; b) \parallel a \parallel b[2]$ 

As a result, the bond between a[2] and b[2] is irreversible since  $\gamma(a, b)$  is undefined.

**Remark.** The interaction between restriction in CCB and concerted rules is unexpected. Consider the following variant of the process introduced in Example 3, defined as follows

 $(((a; b).e.f || a.e.f) \setminus \{e\} || (b.e.f) \setminus \{f\}) \setminus \{e, f\}$ 

with  $\gamma(a, a) = c$  and  $\gamma(b, b) = d$  (i.e., there are no synchronisations for e and f). One would expect this process to be equivalent to the one in Example 3, since the added continuations e and f do not have any chance to be executed because there are no synchronisations for e and f; and, moreover, they are restricted names. However, the behaviour of the two processes differs, because of the concerted reductions. Note that modified version can mimic the first reduction, i.e.,

 $std(\mathbf{S})$  $\left(\mathsf{A}-\underline{\mathsf{STR}}_{m}\right) \xrightarrow[(a[k], c[l], s; b).S]{\underline{\mathsf{su}}(\mathtt{S})} \underline{\mathsf{a}}_{k}^{\underline{\mathsf{a}}[k]} (a[\dagger l], c, s; b).S$ 

[m3G; v1.312] P.7 (1-31)

Theoretical Computer Science ••• (••••) •••-•••

 $(\mathsf{STR}_W) \xrightarrow{std(\mathbb{S}) \quad fresh(k,t)} \\ \xrightarrow{(c,t;b).\mathbb{S} \xrightarrow{c[k]} (c[k],t;b).\mathbb{S}}$ 

 $(WK) \frac{std(S) \quad fresh(k,t)}{(t;b).S \stackrel{(b)[k]}{\longrightarrow} (t;b[k]).S}$ 

 $\left(\mathsf{A}-\underline{\mathsf{STR}}_{p}\right) \xrightarrow[(a[k],s;b[l]).S]{\underline{\mathfrak{std}}(S)} \underline{\mathfrak{std}}(s;b).s$ 

 $(\underline{\mathsf{COM}}) \xrightarrow{\mathbb{P} \xrightarrow{\underline{\mathbf{a}}[k]} \mathbb{P}'} \xrightarrow{\mathbb{Q} \xrightarrow{\underline{\mathbf{c}}[k]} \mathbb{Q}'} {\mathbb{P} \parallel \mathbb{Q} \xrightarrow{\underline{\gamma(\mathbf{a},\mathbf{c})}[k]} \mathbb{P}' \parallel \mathbb{Q}}$ 

 $(PAR) \xrightarrow{\mathbb{P} \xrightarrow{\mu} \mathbb{P}'} fresh(\mu, \mathbb{Q})$  $\xrightarrow{\mathbb{P} \parallel \mathbb{Q} \xrightarrow{\mu} \mathbb{P}' \parallel \mathbb{Q}}$ 

 $(STR_{S}) \xrightarrow{a \in S \quad std(S) \quad fresh(k, s)}{(a, s; b).S \xrightarrow{a[k]} (a[k], s; b).S}$ 

 $(\underline{\mathbf{STR}}) \frac{std(S) \quad s \cap \mathcal{W} \times \mathcal{K} = \emptyset}{(a[k], s; b) \cdot S \xrightarrow{\underline{a}[k]} (a, s; b) \cdot S}$ 

 $(STR_m) \xrightarrow{std(S) \quad fresh(k, s)} (c, a, s; b).S \xrightarrow{c[k]} (c, a[\dagger k], s; b).S$ 

(COM)  $\frac{P \xrightarrow{\mathbf{a}[k]} P' \qquad Q \xrightarrow{\mathbf{c}[k]} Q'}{P \parallel Q \xrightarrow{\gamma(\mathbf{a},\mathbf{c})[k]} P' \parallel Q'}$ 

(CONT)  $\frac{S \xrightarrow{\mu} S' \quad fresh(\mu, t)}{(t; b), S \xrightarrow{\mu} (t; b), S'}$ 

$$\begin{array}{c} (((a; b).e.f \parallel a.e.f) \setminus \{e\} \parallel (b.e.f) \setminus \{f\}) \setminus \{e, f\} \xrightarrow{e_{1}} \\ (((a[1]; b).e.f \parallel a[1].e.f) \setminus \{e\} \parallel (b.e.f) \setminus \{f\}) \setminus \{e, f\} \end{array}$$

At this point, rule (CONCERT) cannot be applied. First note that restrictions cannot be rearranged because e occurs free in  $(b.e.f) \setminus \{f\}$  and f occurs free in  $((a; b).e.f || a.e.f) \setminus \{e\}$ . Hence, the only possibility for the application of (CONCERT) would require: (1)  $((a[1]; b).e.f || a[1].e.f) \setminus \{e\} \xrightarrow{(b)[2]} \xrightarrow{a[1]} and$  (2)  $(b.e.f) \setminus \{f\} \xrightarrow{b[2]} \xrightarrow{a[1]}$ . While (1) holds, (2) clearly does not. The phenomenon is basically due to the fact that the definition of rule (CONCERT) is not compositional.

(RES)  $\xrightarrow{\mathbb{P} \xrightarrow{\mu} \mathbb{P}'}{\mathbb{P} \setminus L \xrightarrow{\mu} \mathbb{P}' \setminus L} n(\mu) \cap L = \emptyset$ 

Fig. 7. Compositional rules for CCB.

### 3. The compositional calculus of covalent bonding

In this section we revise the semantics of CCB presented in section 2. This will help us to better state the correspondence between CCB and covalent bond nets (CBNS). We remodel CCB semantics following these three ideas: (i) we get rid of priority of pre-congruence rules (PROM and MOVE) by applying them directly in the transition rules; (ii) we avoid the looka-head of the CONCERT rule by using a more compact and standard way of gathering labels thorough the parallel operator, more in the line with a synchronisation algebra [34]; and (iii) when a key/bond is passed from a weak action to a strong one (mimicking PROM and MOVE) this key is deemed as invalid (e.g., decorated with †) so to avoid unwanted backward desynchronisations. On the one hand, these modifications make the semantics compositional. On the other hand, the calculus retains the flavour of the original semantics and is consistent with it. The syntax of processes and all the definitions remain the same, when not explicitly specified.

The set of labels is defined below. We extend the set of labels used in the original presentation to account for moves compositionally. Our transition system considers a extended set of label. In addition to the original presentation, we have (i) triples of actions  $(\underline{a}[l], b[k], \underline{c}[l])$  that represents, e.g., the moves of a parallel process in which one part starts the concert with a[l], b[k] and the other contributes with just the complementary reverse c[l]; and (ii)  $\langle b \rangle$  that stands for the execution of a weak action in a strong position (i.e., in the left-hand side of ';') for contributing to a concert rule.

 $\lambda ::= \mathbf{a}[k] \mid (b)[k] \mid \mathbf{a}[k] \mid \langle b \rangle [k]$  $\mu := \lambda | \lambda, \lambda | \lambda, \lambda, \lambda$ 

Define  $key(\mu)$  for the set of keys of a label, we use  $fresh(\mu, s)$  for any key fresh in  $key(\mu)$ . We consider runtime processes in which actions can be marked with a key of the form *t*, which means a bond that has been promoted or moved. In this way the key l cannot be anymore used for backward synchronisations. When we write k, l, we denote keys different from †l.

The rules are reported in Fig. 7 and Fig. 8. Let us briefly comment on them. Rules STRs and STRw allow for the execution of respectively a strong action and a weak action in a strong position (e.g., at the left part of ';'). Note that STR<sub>w</sub> can be applied only when all actions in the prefix but c have been already executed (recall that t ranges over  $\mathbb{N}^{\mathcal{A}\times\mathcal{K}}$ ). STR<sub>m</sub> combines the original rules ACT1 and MOVE: the key k associated with the execution of the weak action c is moved to the strong action a. We remark that rule  $STR_m$  differs from  $STR_w$ , which considers the cases in which every strong action in the prefix has been already executed, and consequently the bond created by the execution of the weak action cannot be moved.

Fig. 8. Compositional concert rules for CCB.

Rule WK accounts for the execution of a weak prefix as in standard CCB. Rule <u>STR</u> allows for the undoing of a strong action provided no weak action in a strong position is marked (i.e., the reverse action cannot be followed by a move). Rule A-<u>STR</u> undoes a strong action and directly *promotes* the weak bond. Analogously, rule A-<u>STR</u> combines the reverse of a strong action with a move. The other rules are defined as in CCB.

The rules for concerted actions are reported in Fig. 8. Rule A-W $\kappa_1$  accounts for the initiation of a concert, which consists of the execution of the weak prefix *b* and the reversal of the strong action <u>a</u> (within the same prefix), which is followed by the move of the weak bond *l* created by the execution of *b*. Note that the weak bond *l* is invalidated after the move. Rule A-W $\kappa_2$  accounts for the transitions in which a prefix contributes to a concert with both a forward weak action and a reversal of a strong action. As in A-W $\kappa_1$ , rule A-W $\kappa_2$  also reflects the move of the weak bond from the weak action to the strong action that is being reversed. Rule A-W $\kappa_3$  is analogous to the previous one, but considers the cases in which the created bond *l* is moved to another strong action in the same prefix. Finally Conc rule deals with concert rule and relies on the definition of the following commutative operation  $\oplus$ , which combines labels as follows

$$\mu_{1} \oplus \mu_{2} = \begin{cases} \underline{a}[k], \langle b \rangle [l] & \text{if } \mu_{1} = \underline{a}[k] \land \mu_{2} = b[l] \\ \mu_{1}, \mu_{2} & \text{if } \mu_{1} = \{\underline{a}[k], (b)[l]\} \land \mu_{2} = c[l] \land \gamma(b, c) \downarrow \\ \mu_{1}, \mu_{2} & \text{if } \mu_{1} = \{\underline{a}[k], (b)[l]\} \land \mu_{2} = \underline{c}[k] \land \gamma(a, c) \downarrow \\ \gamma(a, c)[k], \gamma(b, d)[l] & \text{if } \mu_{1}, \mu_{2} = \{\underline{a}[k], \underline{c}[k], (b)[l], \beta[l]\} \land \beta \in \{c, (c), \langle c \rangle\} \end{cases}$$

The first case allows for the combination of parallel process that contribute with a reverse action  $\underline{a}[k]$  and a forward weak action in a strong position b[l]. Note that  $\underline{a}[k] \oplus b[l] = \underline{a}[k] \oplus \langle b \rangle[l]$ , where  $\langle b \rangle[l]$  reflects the fact that both actions are intended to contribute to a concert. The following two cases account for the situations in which one parallel branch contributes with the label that indicates the starting of a concert, i.e.,  $\{\underline{a}[k], (b)[l]\}$ , and the other with the complementary forward (c[l]) or backward  $(\underline{c}[k])$  action. The last case deals with a concerted move in which the labels of the different branches contribute with all needed actions.

**Example 4.** Consider the molecules A = (c; q), B = (d, q) and C = (c, d) with  $\gamma(c, c) = f$ ,  $\gamma(d, d) = e$  and  $\gamma(q, q) = a$  defined in Example 2. We have the following reductions:

$$A \parallel B \parallel C \xrightarrow{f[1]} (c[1];q) \parallel B \parallel (c[1],d) \xrightarrow{e[2]} (c[1];q) \parallel (d[2],q) \parallel (c[1],d[2])$$

Then, we have the following derivation:

$$\underbrace{ (c[1];q) \xrightarrow{(q)[3],\underline{c}[1]} (c[\dagger 3];q) }_{(c[1];q) \parallel (c[\dagger 2],q) \parallel (c[1],d[2]) \xrightarrow{(q)[3],\underline{c}[1]} (d[2],q[3]) \parallel (c,d[2]) }_{(d[2],q) \parallel (c[1],d[2]) \xrightarrow{(q)[3],\underline{c}[1]} (d[2],q[3]) \parallel (c,d[2]) }_{(c[1];q) \parallel (d[2],q) \parallel (c[1],d[2]) \xrightarrow{(a[3],\underline{f}[1])} (c[\dagger 3];q) \parallel (d[2],q[3]) \parallel (c,d[2]) }$$

Let us note that the label  $\langle q \rangle [3], \underline{c}[1]$  is obtained as the result of  $q[3] \oplus \underline{c}[1]$ . This example is borrowed from [8]. Now, the bond between the actions d identified with the key 2 can be undone.

$$(\mathtt{c}[\dagger 3];q) \parallel (\mathtt{d}[2],q[3]) \parallel (\mathtt{c},\mathtt{d}[2]) \xrightarrow{\underline{\mathtt{e}}[2]} (\mathtt{c}[\dagger 3];q) \parallel (\mathtt{d}[\dagger 3],q) \parallel (\mathtt{c},\mathtt{d})$$

Note that the final configuration differs from the final one in Example 2 because promotion and move of weak bonds take place instantaneously. Nonetheless, the original semantics of CCB requires the application of pre-congruence rules before deriving new transitions from the final configuration of Example 2, which would produce the similar configuration  $(c[3]; q) \parallel (d[3], q) \parallel (c, d)$  (if we disregard †). Our semantics deviates from the original definition of CCB in the treatment of promoted bonds, which are not reversible in our case. Note that  $(c[†3]; q) \parallel (d[†3], q) \parallel (c, d)$  would be unable to break for the treatment for the final configuration of the treatment for the treatment f JID:TCS AID:13224 /FLA Doctopic: Theory of natural computing H. Melgratti, C.A. Mezzina and G.M. Pinna

[m3G; v1.312] P.9 (1-31) Theoretical Computer Science ••• (••••) •••-•••

the bond †3 between c and q even if c and q were synchronisable. After noting that none of the examples in [8] exploit such a mechanism, we adopted this constraint that simplifies our encoding.

**Example 5.** Consider the process  $(a; b) \parallel a \parallel b$  with  $\gamma(a, a) = c$  and  $\gamma(b, b) = d$  defined in Example 3. We have the following reductions:

 $(a; b) \| a \| b \xrightarrow{\gamma(a, a)[1]} (a[1]; b) \| a[1] \| b \xrightarrow{\mu_1 \oplus \mu_2} (a[\dagger 2]; b) \| a \| b[2]$ 

where  $\mu_1 = (b)[2], \underline{a}[1]$  and  $\mu_2 = \langle b \rangle [2], \underline{a}[1]$ . Let us note that  $\mu_2$  is the result of two actions in parallel performed by a[1] and b. With respect to the Example 3 (and in general with the original CCB) we can notice that the promotion of a weak bond to a strong one is done automatically in the rule, and not via auxiliary pre-congruence rules. In this way we get rid of priority on rules. Also, we use † to indicate a promoted (or moved) bond, which cannot participate anymore in any synchronisation.

**Definition 3.** A context  $\subset$  is a process with a hole  $\bullet$ , which is defined by the following grammar:

 $C[\bullet] ::= (\bullet, s; \beta).C \mid (s; \bullet).C \mid C \mid Q \mid Q \mid C \mid C \setminus L$ 

We now give the definition of well-formedness for both prefixes and processes. Intuitively a prefix is well-formed if its keys are pair-wise different (e.g., there are no repetitions); invalid keys are associated only with strong actions; and a weak action is marked only if all other strong actions are marked. Condition for a process P to be well-formed are a bit more involved. Let us comment on them. The first condition tells that if the process P is a prefix of the form  $(s; \beta)$ . S then they key used by the prefix  $(s; \beta)$  are disjoint from the keys of its continuation S and if S has some executed actions then the weak action of the prefix does not bear any key. A parallel composition  $P_1 \parallel P_2$  is well-formed if the two processes are well-formed and they do not have marked weak prefixed. Also, the shared keys have to be used once per part, meaning that there has been a syncrhonization. To this end we have three sub-cases: (i) either a shared key k marks two action which are not restricted by their respective contexts: (ii) the key is used to invalidate (via  $\dagger$ ) a strong action in one part of the parallel and in the other part it is used to mark a weak action; or (iii) in both parts the key is used to invalidate a strong action. Finally, the process  $P \setminus L$  is well-formed if P is well-formed. 

We now give the definition of well-formedness for both prefixes and processes.

**Definition 4.** A prefix  $(s; \beta)$  is well-formed if

1.  $key(s; \beta)$  is a set; and

2.  $\forall c \in \mathcal{W}, k \in \mathcal{K}, s(c[\dagger k]) = 0 \text{ and } \beta \neq c[\dagger k].$ 

3.  $\forall c \in \mathcal{W}, k \in \mathcal{K}$ , if  $s, \beta(c[k]) = 1$  then  $s \in \mathcal{A} \times \mathcal{K}$ .

A process P is well-formedness if:

1.  $\mathbb{P} = (s; \beta).\mathbb{S}$ , and  $(s; \beta)$  and  $\mathbb{S}$  are well-formed, and  $key(s; \beta) \cap key(\mathbb{S}) = \emptyset$ , and  $key(\mathbb{S}) \neq \emptyset$  implies  $s \in \mathbb{N}^{\mathcal{A} \times \mathcal{K}}$  and  $\beta \in \mathcal{A}$ . 2.  $\mathbb{P} = \mathbb{P}_1 \| \mathbb{P}_2$ , and  $\mathbb{P}_1$  and  $\mathbb{P}_2$  are well-formed and free from executed weak prefixes, and for all  $k \in \mathcal{K}$  if  $k \in key(\mathbb{P}_1) \cap key(\mathbb{P}_2)$ then  $key(P_1)(k) = key(P_2)(k) = 1$  and one of the following holds

i  $P_1 = C_1[a[k]]$  and  $P_2 = C_2[b[k]]$  and  $\gamma(a, b) \downarrow$ ,  $a \notin bn(C_1[])$  and  $b \notin bn(C_2[])$ .

- ii  $P_1 = C_1[a[\dagger k]]$  and  $P_1 = C_2[b[k]]$  and  $a \in S$ ,  $b \in W$ ,  $a \notin bn(C_1[])$  and  $b \notin bn(C_2[])$ .
- iii  $P_1 = C_1[a[\dagger k]]$  and  $P_1 = C_2[b[\dagger k]]$  and  $a, b \in S$ ,  $a \notin bn(C_1[])$  and  $b \notin bn(C_2[])$ .

3.  $P = P_1 \setminus L$  and  $P_1$  is well-formed.

**Lemma 1.** If P is well-formed then  $\forall k \in \mathcal{K}.key(P)(k) \leq 2$ .

**Proof.** By a straightforward induction on the structure of P.

**Lemma 2.** If P is well-formed and  $P \xrightarrow{\mu} P'$ , then P' is well-formed.

**Proof.** By induction on the derivation and with a case analysis on the last applied rule. All the cases are simple. The main idea is that all keys are freshly generated, and through COM or CONC keys are forced to match if a synchronisation can happen. It is here the only place in which two instances of the same key k can be generated, and these instances depending on the rule used to derive the label can be used to mark a strong action, to invalidate a strong action or to mark a weak action.  $\Box$ 

### Theoretical Computer Science ••• (••••) •••-•••

4. Nets

We summarise the basics of Petri net with inhibitor arcs along the lines of [35,36]. A net is the triple (S, T, F) where S is a set of *places*, T is a set of *transitions* such that  $S \cap T = \emptyset$  and  $F \subseteq (S \times T) \cup (T \times S)$  is the *flow* relation.

**Definition 5.** A *Petri net* is a pair  $N = (\langle S, T, F \rangle, m)$  where  $\langle S, T, F \rangle$  is a net and  $m \in \mu S$  is the *initial marking*.

**Definition 6.** A *Petri net with inhibitor arcs* (IPT for short) is the pair  $N = (\langle S, T, F, I \rangle, m)$ , where  $(\langle S, T, F \rangle, m)$  is a Petri net and  $I \subseteq S \times T$  is the *inhibiting* relation.

Given an IPT  $N = (\langle S, T, F, I \rangle, m)$  and  $x \in S \cup T$ , the *pre*- and *postset* of *x* are respectively defined as the (multi)sets  $\bullet x = \{y \mid (y, x) \in F\}$  and  $x^{\bullet} = \{y \mid (x, y) \in F\}$ . If  $x \in S$  then  $\bullet x \in \mu T$  and  $x^{\bullet} \in \mu T$ ; analogously, if  $x \in T$  then  $\bullet x \in \mu S$  and  $x^{\bullet} \in \mu S$ . The *inhibitor set* of a transition *t* is the (multi)set  $\circ t = \{s \mid (s, t) \in I\}$ . The definition of  $\bullet \cdot, \bullet^{\bullet}, \circ^{\circ}$  generalise straightforwardly to multisets of transitions.

**Example 6.** Consider the IPT *N* depicted in Fig. 9, which consists of six places depicted as circles and three transitions drawn as boxes. The flow relation is represented by black arrows while the inhibitor relation is shown by red lines ended with a small circle. The initial marking  $m = \{s_1, s_2, s_3\}$  is represented by the bullets drawn within the corresponding places. Consider, for instance, the transition *b*: it consumes tokens from  $s_2$  and  $s_3$ , produces a token in  $s_5$ , and is inhibited by  $s_1$ . Hence, its pre-, post- and inhibiting sets are respectively  ${}^{\bullet}b = \{s_2, s_3\}$ ,  $b^{\bullet} = \{s_5\}$ , and  ${}^{\circ}b = \{s_1\}$ .

A (multiset of) transition(s)  $A \in \mu T$  is enabled at a marking  $m \in \mu S$ , written  $m[A\rangle$ , whenever  $\bullet A \subseteq m$  and  $\forall s \in \circ A$ .  $m(s) = 0 \land A^{\bullet}(s) = 0$ . The last condition requires the absence of tokens in all places connected via inhibitor arcs to the transitions in A. Observe that the multiset  $\emptyset$  is enabled at every marking. A (multiset of) transition(s) A enabled at a marking m can fire and its firing produces the marking  $m' = m - \bullet A + A^{\bullet}$ . The firing of A at a marking m is denoted by  $m[A\rangle m'$ . We assume that each transition t of an IPT N is defined such that  $\bullet t \neq \emptyset$ , i.e., it cannot fire spontaneously in an uncontrolled manner without consuming tokens. Moreover, we assume that there are no isolated places, i.e., for all place s, there exists a transition t such that  $s \in \bullet t \cup t^{\bullet} \cup \circ t$ .

**Example 7.** Consider the IPT introduced in Example 6 and note that both *a* and *c* are enabled at the initial marking *m*. On the contrary, *b* is not enabled because its inhibitor place  $s_1$  contains a token. The firing of *a* produces the marking  $m' = \{s_2, s_3, s_4\}$ , i.e.  $m[a \rangle m'$ , at which *b* becomes enabled because its preset  $s_2$  and  $s_3$  is marked while its inhibitor place  $s_1$  is not.

A marking *m* is *reachable* in *N* if there exists a firing sequence  $\sigma = m[A_0\rangle m_1 \cdots m_n[A_n\rangle m$  from the initial marking *m* to *m*. We write  $\mathcal{M}_N$  for the set of all reachable markings of *N*.

**Example 8.** The set of reachable markings of the IPT in Example 6 is  $\mathcal{M}_{N_1} = \{m, \{s_2, s_3, s_4\}, \{s_1, s_2, s_6\}, \{s_4, s_5\}, \{s_2, s_4, s_6\}\}$ .

An IPT *N* is *safe* if each reachable marking is a set. Hereafter, we will consider only safe IPT. Given a net  $N = (\langle S, T, F, I \rangle, m)$  and a subset  $T' \subseteq T$  of transitions the subnet generated by T' is the net  $(\langle S', T', F', I' \rangle, m')$  where  $S' = {}^{\bullet}T' \cup T'^{\bullet} \cup {}^{\circ}T', F' = F \cap ((S' \times T') \cup (T' \times S')), I' = I \cap (S' \times T')$  and m' is the restriction of m to the places in S'.

**Example 9.** Consider again the IPT *N* of Fig. 9, and take  $T' = \{a\}$ . The places of the subnet identified by  $\{a\}$  are  $s_1$  and  $s_4$  and the flow arcs are  $(s_1, a)$  and  $(a, s_4)$ , there are no inhibitor arcs and only  $s_1$  is initially marked. It the subset of transitions were  $\{b\}$  then the subnet would have  $s_1, s_2, s_3$  and  $s_5$  as places,  $(s_2, b), (s_3, b)$  and  $(b, s_5)$  as flow arcs,  $(s_1, b)$  as inhibitor arcs. Its initial marking would assign tokens to  $s_1, s_2, s_3$  (but not to  $s_5$ ).

**Definition 7.** Let  $N = (\langle S, T, F, I \rangle, m)$  be an IPT. *N* can be partitioned into *k* components if there exists a partition  $\{T_1, \ldots, T_k\}$  of the set of transitions *T* such that

•  $\{S_1, \ldots, S_k\}$  is a partition of the set of places *S*.

A net can be partitioned if it consists of a set of disjoint subnets, i.e., there is no arc connecting a place in  $S_i$  with a transition in  $T_j$ , if  $i \neq j$ . It is worth observing that the IPT N is  $(\langle \bigcup_{i \in \{1,...,k\}} S_i, \bigcup_{i \in \{1,...,k\}} T_i, \bigcup_{i \in \{1,...,k\}} F_i, \bigcup_{i \in \{1,...,k\}} I_i \rangle$ ,  $\bigcup_{i \in \{1,...,k\}} m_i$ ) because we consider nets without isolated places.

**Example 10.** Consider the net N in Fig. 10. It can be partitioned into two subnets, namely  $N_1$  (with places  $s_1, s_2, s_4$  and  $s_5$ ) and transitions *a* and *b*) and  $N_2$  (with places  $s_3$  and  $s_6$  and transition *c*).

When establishing the correspondence between nets and terms of CCB the name of the executed transitions will play a fundamental role, hence we consider labelled nets, where the labelling mapping is defined as a total mapping of transitions into a set of labels L.

**Definition 8.** A labelled Petri net with inhibitor arcs (LIPT for short) is a pair  $N = (\langle S, T, F, I, \ell \rangle, m)$ , where  $(\langle S, T, F, I \rangle, m)$  is an IPT and  $\ell: T \to L$  is a labelling function.

The notion of partition is lifted to labelled nets in the obvious way.

### 5. Covalent bond nets

Δ

We restrict our attention to a class of nets in which dependencies are represented through inhibitor arcs, along the lines of [17]. We introduce a class of contextual Petri nets, baptized *bond nets*, which consists of several components in which (i) dependencies are mainly recovered from the inhibiting relation instead of the usual flow relation, and (ii) synchronisations (bonds) among components are allowed under suitable assumptions.

We consider a set of labels L, the precise structure of which will be made explicit later. For now, we assume that L contains a non empty subset  $L_{W} \subset L$  of weak labels, and a non empty subset  $L_{S} \subset L$  of strong labels. For the sake of the simplicity, we omit the marking of LIPT in the following definitions because the class of bond nets is defined only in terms of the structure of the net.

**Definition 9.** Let  $N = \langle S, T, F, I, \ell \rangle$  be an LIPT. N is a *basic* net if the following conditions are satisfied:

1.  $\forall t, t' \in T$ .  $\bullet t' \cap t^{\bullet} = \emptyset$ ; 2.  $\forall t \in T$ .  $\bullet t \neq \emptyset$  and  $t^{\bullet} \neq \emptyset$ ; and 3.  $\forall t \in T$ . °*t* is finite.

The conditions imposed on basic nets share motivations with occurrence nets [37], unravel nets [38-40] and flow nets [41], in which computations are explained without resorting to firing sequences, as it will be clearer when discussing the notion of configuration. For now it is enough to observe that the execution of some transition can be inferred by looking at the postset of it, though this could not be the unique condition. The first condition implies that dependencies in basic nets do not arise because of the flow relation. The second condition ensures that each transition is not allowed to fire spontaneously (non empty preset) and that some effect of its firing can be observed (non empty postset). The third condition implies that each transition has a finite set of inhibiting places, which suggests that the dependencies of each transition are finite.

The notion of basic net is further refined into the one of *pre-bond* net, where the labels play a major role.

**Definition 10.** Let  $N = \langle S, T, F, I, \ell \rangle$  be a basic net,  $T_{\mathcal{S}} = \{t \in T \mid \ell(t) \in \mathsf{L}_{\mathcal{S}}\}$  and  $T_{\mathcal{W}} = \{t \in T \mid \ell(t) \in \mathsf{L}_{\mathcal{W}}\}$  be subsets of transitions. N is a pre-bond net (pBN for short) if the following further conditions are satisfied:

[m3G; v1.312] P.12 (1-31)

### Theoretical Computer Science ••• (••••) •••-•••

1.  $T_{S} \neq \emptyset \neq T_{W}$ ;

2.  $\forall t \in T_{\mathcal{S}} \cup T_{\mathcal{W}}$ .  $|\bullet t| = 1$ ;

3.  $\forall t \in T_S$ .  $\circ t = \emptyset$ ; and 4.  $\exists !t \in T_{\mathcal{W}}$ .  $\circ t = \bullet T_{\mathcal{S}} \cup \bullet (T_{\mathcal{W}} \setminus \{t\})$ . In a pbn there must be transitions labelled in  $L_8$  and in  $L_W$ , and these transitions have just a single place in their preset. Transitions with the same label in  $L_S \cup L_W$  may share the same preset. Transitions with labels in  $L_S$  are such that their inhibitor set is empty, and there exists a unique transitions labelled in  $L_W$  which is inhibited by all the other transitions with labels in L<sub>8</sub> and in L<sub>W</sub>. This transition is called *weak*, since it can be fired only when all the other transitions with labels in  $L_S$  and  $L_W$  have been executed. The weak transition can be identified and denoted as weak(N), provided that N is a pbn. Thus weak $(N) = \{t \in T \mid \ell(t) \in L_W \land {}^{\circ}t = {}^{\bullet}T_{\mathcal{S}} \cup {}^{\bullet}(T_W \setminus t)\}$  is the set containing the weak transition and strong $(N) = \{t \in T \mid \ell(t) \in L_W \land {}^{\circ}t = {}^{\bullet}T_{\mathcal{S}} \cup {}^{\bullet}(T_W \setminus t)\}$  $T_S \cup T_W \setminus \text{weak}(N)$  are all the transitions in a pBN that are not weak and have a label in  $L_S \cup L_W$ , which we call strong transition. It should be stressed that a strong transition may have a weak label, but a weak transition should have a weak label.

**Example 11.** The net in Fig. 11 is a pBN where the set weak(N) contains the transition b and the set of strong transitions is  $strong(N) = \{a, c\}.$ 

**Proposition 1.** Let  $N = \langle S, T, F, I, \ell \rangle$  be a pBN. Then weak(N) is a singleton.

**Proof.** It follows from the definition of pbn.  $\Box$ 

**Definition 11.** Let  $N = \langle S, T, F, I, \ell \rangle$  be a pBN. N is *stratified* if there exists a partition of places and transitions indexed by  $\mathcal{I}$ such that  $S = \bigcup_{i \in \mathbb{T}} S_i$ ,  $T = \bigcup_{i \in \mathbb{T}} T_i$ ,  $F = \bigcup_{i \in \mathbb{T}} F_i$ ,  $m = \bigcup_{i \in \mathbb{T}} m_i$ ,  $\ell_i$  is  $\ell$  restricted to the transition in  $T_i$ , and

1.  $\forall i \in \mathcal{I}$ .  $N_i = (\langle S_i, T_i, F_i, I \cap S_i \times T_i, \ell_i \rangle, m_i)$  is a pre-bond net; and 2.  $\forall t \in T_i \text{ either } \circ \text{strong}(N_i) = \emptyset \text{ and } \circ \text{weak}(N_i) = \bullet \text{strong}(N_i) \text{ or there exists a unique } j \in \mathcal{I}. \circ t \setminus S_i = \bullet \text{strong}(N_i) \cup \text{weak}(N_j) \bullet.$ 

For each  $i \in \mathcal{I}$  we say that  $N_i$  is a part of the stratified pre-bond net N, and it is denoted by  $\mathcal{C}(N, i)$ . A stratified pre-bond net is a net formed by pre-bond nets that are only connected by inhibitor arcs, and the transitions of one of the components which are inhibited by places in another component, are all inhibited by the same subset of places. The weak transitions of a stratified pBN can be identified, as they are the union of the weak transitions of each component. With abuse of notation, we write weak(N) =  $\bigcup_{i \in \mathcal{I}}$  weak( $\mathcal{C}(N, i)$ ) for the set of weak transitions.

**Example 12.** The net in Fig. 12 is a stratified one. It has two parts  $\mathcal{C}(N, 1)$  and  $\mathcal{C}(N, 2)$ . The net  $\mathcal{C}(N, 1)$  is the one depicted in Fig. 11, whereas  $\mathcal{C}(N, 2)$  is the net with places  $\{s_7, s_8, s_9, s_{10}\}$ , transitions d and e. The weak transition e is inhibited by the place  $s_7$  (depicted with a red inhibitor arc in Fig. 12) and the two transitions are inhibited by some places belonging to the simple net  $\mathcal{C}(N, 1)$ , namely the places  $s_1$ ,  $s_3$  and  $s_5$ .

**Definition 12.** Let  $N = \langle S, T, F, I, \ell \rangle$  be a stratified pb. We say that it is *well-stratified* if the set of index  $\mathfrak{I}$  can be totally ordered and  $\forall i \in \mathcal{I}$ .  $\forall t \in T_i$  if  ${}^{\circ}t \notin S_i$  then  ${}^{\circ}t \subseteq S_j$  with *j* being the immediate predecessor of *i*.

The fact that  $\mathcal{I}$  can be totally ordered implies that there is a bijection between  $\mathcal{I}$  and  $\{1, \ldots, n\}$  with  $n = |\mathcal{I}|$ , where the notion of immediate predecessor, if needed, is just minus one. If the set of indexes  $\mathfrak{I}$  can be totally ordered, we write  $\mathsf{fst}(\mathfrak{I})$ for the minimum of J. 

**Example 13.** The net in Fig. 12 is well-stratified. Indeed, its two components are  $\mathcal{C}(N, 1)$  and  $\mathcal{C}(N, 2)$  and the set of indexes is {1, 2} ordered as natural numbers.

Fig. 11. A simple pBN.

<sup>59</sup> So far we have considered nets where a transition that could be interpreted as a synchronisation is not present. We <sup>60</sup> characterize the transitions that, beside the key places, have the same effect of the execution of other two transitions, and <sup>61</sup> that may be executed whenever the two transitions can be executed.

60

Fig. 14. A net N with a bond transition.

•  $^{\circ}t = ^{\circ}t_1 \cup ^{\circ}t_2$ . dent subnets.

**Definition 14.** Let  $N = \langle S, T, F, I, m, \ell \rangle$  be a LIPT. We say that  $t \in T$  is a bond transition if there exists  $t_1, t_2 \in T$  with  $t_1 \cap t_2 = \emptyset$  and  $t_1 \cap t_2 = \emptyset$  such that

•  $t = t_1 \cup t_2;$ 

•  $t^{\bullet} \setminus k(t) = t_1^{\bullet} \setminus k(t_1) \cup t_2^{\bullet} \setminus k(t_2)$ ; and

The transition t is a bond between the transitions  $t_1$  and  $t_2$ , and it conveys the idea that the execution of t has the same effects as the execution of both beside the key places, which in this case will record that the bond transition t has been executed and not the two ones.

**Definition 15.** Let  $N = \langle S, T, F, I, m, \ell \rangle$  be a LIPT. We say that the subset of transition  $T' \subset T$  such that

•  $\forall t \in T'$ . *t* is a bond transition; and

• • $(T \setminus T') \cup (T \setminus T')^{\bullet} = S \setminus (\bigcup_{t \in T'} \mathsf{k}(t));$ 

is the set of *bond* transitions of N and it is denoted with bond(N).

A transition in bond(N) can be possibly removed without changing the reachable markings, beside the possible keys, which do not contribute to the enabling or disabling of any transition. A bond transition will be used to bond two indepen-

**Example 15.** In the net depicted in Fig. 14 the transition *e* bonds the two transition *a* and *c*: beside the key places of these two transitions, e has the same effect (without its key place). In the net N the set bond(N) contains just the transition e.

We are now ready to define what a bond net is, capturing the intuition that a bond net is made by some well-stratified components which are connected using bonds.

**Definition 16.** Let  $N = (S, T, F, I, \ell)$  be a LIPT, let bond(N)  $\subseteq T$  be the set of bond transitions of N, and let  $S_{bond(N)}$  be the set of keys of the bond transitions  $\{s \in S \mid \exists t \in bond(N), s \in k(t)\}$ . We say that N is a bond nets (BN for short) if there exists a set of indexes  $\mathcal{Y}$  such that  $\{T_i \mid i \in \mathcal{Y}\}$  is a partition of the set of transitions  $T \setminus bond(N)$  and

- for each  $i \in \mathcal{Y}$  the net  $N_i = \langle S_i, T_i, F_i, I_i, \ell_i \rangle$  is a well-stratified pBN, where  $S_i = {}^{\bullet}T_i \cup T_i {}^{\bullet} \cup {}^{\circ}T_i, F_i, I_i$  and  $\ell_i$  are the restrictions of F, I,  $\ell$  to transitions and places in  $S_i$  and  $T_i$ ;
- $\langle \bigcup_{i \in \mathcal{Y}} S_i, \bigcup_{i \in \mathcal{Y}} T_i, \bigcup_{i \in \mathcal{Y}} F_i, \bigcup_{i \in \{1, \dots, k\}} I_i, \bigcup_{i \in \mathcal{Y}} \ell_i \rangle$  is the net  $\langle S \setminus S_{bond(N)}, T \setminus bond(N), F', I', \ell \rangle$ , where F', I' and  $\ell'$  are F, I and  $\ell$  restricted to transitions in  $T \setminus bond(N)$  and places in  $S \setminus S_{bond(N)}$ ; and
- for each  $t \in bond(N)$  there exists two indexes i, j with  $i \neq j$  such that  $t \subseteq S_i \cup S_i$ ,  $t \land k(t) \subseteq S_i \cup S_i$  and  $|t \cap S_h| = 1 = 1$  $|t^{\bullet} \cap S_h|$ , with  $h \in \{i, j\}$ .

The first two conditions simply state that the net without the bond transitions and the associated keys places can be partitioned into well-stratified pBNs, and the last one requires that each transition in bond(N) bonds just two of these subnets.  $\mathcal{Y}$  denotes the set of the indexes of the partition and each well-stratified subnet is identified with  $\mathcal{P}(N, j)$  for  $j \in \mathcal{Y}$ .

**Example 16.** The net in Fig. 14 is a bond net whose two components are depicted in Fig. 15.

Given a bond net N, we can assume that the sets of indexes associate to the stratification of each well-stratified component  $\mathcal{P}(N, j)$  is such that  $\mathcal{I}_i \cap \mathcal{I}_l = \emptyset$  for each  $j \neq l$ .

We now turn our attention to markings.

Δ

Fig. 16. The net N in Fig. 14 with the transitions reversing a, c and the bond e.

**Definition 20.** Let  $N = \langle S, T, F, I, \ell \rangle$  be an LIPT. We say that it is a *covalent* bond net (CBN) if there exists a subset  $U \subseteq T$  of transitions such that

1.  $N' = \langle S', T', F', I', \ell' \rangle$ , where  $T' = T \setminus U$ ,  $S' = {}^{\bullet}T' \cup T'^{\bullet} \cup {}^{\circ}T'$  and F', I' and  $\ell'$  are the restrictions of F, I and  $\ell$  to the transitions in T' and places in S', is a bond net with  $\mathcal{Y}$  components  $\mathcal{P}(N', j) = \langle S_j, T_j, F_j, I_j, \ell_j \rangle$  with  $j \in \mathcal{Y}$ ;

2.  $\forall u \in U$ .  $\bullet u \cap \text{keys}(N') \neq \emptyset$ ;

3.  $\forall j \in \mathcal{Y}, \forall t \in \text{strong}(\mathcal{P}(N', j)). \exists ! u \in U \text{ such that } \bullet t = u \bullet, t \bullet = \bullet u \text{ and } \ell(u) = \ell(t); \text{ and }$ 

4.  $\forall t \in bond(N')$ .  $\exists ! u \in U$  such that  $\bullet t = u \bullet$ ,  $t \bullet = \bullet u$  and  $\ell(u) = \ell(t)$ .

A covalent bond net is a bond net where the added transitions connecting the various components are either transitions reversing the effect of some forward transitions in the net, or these transitions somehow *concert* more complex activities, some of them has happened, henceforth these transitions use key-places. In Fig. 16 the classical reversing transitions are depicted: these transitions simply undo either a bond or some strong transition.

The definition of covalent bond net is rather liberal but it conveys the two main features we are interested in:

- the net is formed by *sequential* components interacting together, and these components have a specific form (well-stratified nets); and
- the interaction between these components are via bonds and concerting transition, where forward interactions produce keys, and other interactions use the keys produced by these interactions.

### 6. CCB and covalent bond nets

This section presents the encoding of CCB terms as labelled CBNS, i.e., CBNS are equipped with a labelling function that maps transitions to labels. We consider the following set L of labels:

 $\begin{array}{ll} I ::= & a \mid \underline{a} \mid (b) \mid \langle b \rangle \\ L ::= & I \mid I, I \mid I, I, I \end{array}$ 

They are basically the CCB labels, without keys, as information on keys is inferred from key places. The totally undefined labelling mapping is written as  $\perp$ .

For a process P, we write  $\mathcal{N}(P)$  for the associated net  $\langle S, T, F, I, \ell \rangle$  and  $\mathcal{M}(P)$  for the associated marking. We first describe and discuss on how the net part of the encoding is defined, and then formalize the associated marking. The encoding is defined inductively on the structure of processes.

The terminated process 0 is encoded as the empty net.

**Definition 21.**  $\mathcal{N}(0) = \langle \emptyset, \emptyset, \emptyset, \emptyset, \bot \rangle$  is the net associated to the term 0.

**Lemma 3.** The net  $\mathcal{N}(\mathbf{0})$  is a CBN.

Proof. Trivial.

The marking associated to 0 is  $\mathcal{M}(0) = \emptyset$ , hence the marked net associate to 0 is  $(\mathcal{N}(0), \mathcal{M}(0))$ . The marking  $\emptyset$  is clearly a feasible marking.

The encoding of a prefixed process is defined in terms of the auxiliary encoding of prefixes defined below. Intuitively, the net associated with a prefix generates several transitions to encode the behaviour associated with each inference rule of the operational semantics.

Let (s; b) be the prefix to be encoded, then the set of transitions associated with rule  $STR_s$  are the following:

 $T_{\text{STR}_{s}}(s; b) = \{ \langle a, i \rangle \mid a \in S \land 1 \le i \le s(a) \}$ 

JID:TCS AID:13224 /FLA Doctopic: Theory of natural computing H. Melgratti, C.A. Mezzina and G.M. Pinna [m3G; v1.312] P.17 (1-31) Theoretical Computer Science ••• (••••) •••--•••

Basically, the occurrence of a strong action a in *s* is mapped to a transition  $\langle a, i \rangle$ , where the natural  $i \in \mathbb{N}$  is used to disambiguate different occurrences of the same action a in *s*. A transition  $\langle a, i \rangle$  has the place  $*\langle a, i \rangle$  as its pre set and the places  $\langle a, i \rangle^{\dagger}$  and  $\langle \underline{a}, i \rangle^{\dagger}$  as its post set, i.e.,

$$^{\bullet}\langle \mathbf{a}, i \rangle = \{^{*}\langle \mathbf{a}, i \rangle\} \qquad \langle \mathbf{a}, i \rangle^{\bullet} = \{\langle \mathbf{a}, i \rangle^{*}, \langle \mathbf{a}, i \rangle^{\dagger}\}$$
(1)

The place  $\langle a, i \rangle^*$  indicates that the i-th occurrence of a has been fired, while  $\langle \underline{a}, i \rangle^{\dagger}$  states that the key has been originated from the execution of a (in contraposition to keys obtained by promotion or moves, as will be discussed later). Besides, we do not associate any inhibitor arc with this transitions, i.e.,

$$^{\circ}\langle a,i\rangle = \emptyset$$

The labels associated to those transitions are the associated actions, i.e.,

$$\ell \langle a, i \rangle = a$$

For the sake of simplicity, the arcs associated to these transitions are denoted as  $F_{STR_s}$  (the set of inhibitor arcs for these transition is empty), and the labelling mapping for these transitions  $\ell_{STR_s}$ .

The set of transitions associated to the instances of the rule  $STR_W$  is as follows.

$$T_{\text{STR}_{W}}(s; b) = \{ \langle c, 1 \rangle \mid c \in \mathcal{W} \cap s \}$$

We remark that this set can have at most one transition, since at most one weak action can be in the strong part of a prefix. The pre and post sets of the transitions are defined analogously, i.e.,

• 
$$\langle c, 1 \rangle = \{ \langle c, 1 \rangle \}$$
  $\langle c, 1 \rangle^{\bullet} = \{ \langle c, 1 \rangle^{*}, \langle \underline{c}, 1 \rangle^{\dagger} \}$ 

However, the set of inhibitor places is not empty, i.e., this transition will be enabled after every other strong action in the prefix have been already executed

$$^{\circ}\langle c,1\rangle = \{^{*}\langle a,i\rangle \mid a \in S \land 1 \le j \le s(a)\}$$

Also in this case the label is the action, i.e.,  $\ell \langle c, 1 \rangle = c$ .  $F_{STR_w}$  and  $I_{STR_w}$  are the flow arcs and inhibitor arcs for these transitions, and the labelling is  $\ell_{STR_w}$ .

The set of transitions for mimicking  $STR_m$  is

$$T_{\text{STR}_m}(s; b) = \{ \langle c, a, i \rangle \mid c \in \mathcal{W} \cap s \land a \in S \land 1 \le i \le s(a) \}$$

A transition (c, a, i) represents the execution of the weak action *c* in the strong part of the prefix followed by a move of the generated bond to the strong action *a*.

• 
$$\langle c, a, i \rangle = \{ * \langle a, i \rangle \}$$
  $\langle c, a, i \rangle^{\bullet} = \{ \langle a, i \rangle^{*} \}$ 

In addition, we use inhibitor arcs to enforce the availability of *c*, i.e.,

$$^{\circ}\langle c, a, i \rangle = \{\langle c, 1 \rangle^*\}$$

The pre set and post set of  $\langle c, a, i \rangle$  resemble those of  $\langle a, i \rangle$ ; however, we do not produce a key, to recall that the bond is due to a move and hence invalidated, i.e.,  $\dagger k$ . In this case, the label corresponds to the weak action, i.e.,  $\ell \langle c, a, i \rangle = c$  and  $F_{\text{STR}_m}$  and  $I_{\text{STR}_m}$  are the flow arcs and inhibitor arcs for these transitions, whereas  $\ell_{\text{STR}_m}$  is the labelling mapping.

The set of transitions for mimicking wk is

$$T_{WK}(s; b) = \{\langle b, 0 \rangle\}$$

The pre, post and inhibitor sets are, as expected,

$$^{\bullet}\langle b, 0 \rangle = \{^{*}\langle b, 0 \rangle\} \qquad \langle b, 0 \rangle^{\bullet} = \{\langle b, 0 \rangle^{*}, \langle \underline{b}, 0 \rangle^{\dagger}\}$$

and

$$^{\circ}\langle b, 0 \rangle = \{^*\langle a, i \rangle \mid a \in \mathcal{A} \land 1 \le j \le s(a)\}$$

In this case, the label corresponds to the weak action, i.e.,  $\ell \langle b, 0 \rangle = b$ .  $F_{WK}$  and  $I_{WK}$  are the flow arcs and inhibitor arcs for these transitions,  $\ell_{WK}$  the labelling mapping.

Observe that this is a weak transition.

**Fig. 17.** Forward transitions for the encoding of (a, *c*; *b*).

**Example 17.** Consider the prefix (a, c; b). The encoding of transition rules corresponding to forward transitions is shown in Fig. 17. The transition  $\langle a, 1 \rangle$  accounts for the execution of the strong action a in the prefix. The transition  $\langle b, 0 \rangle$  corresponding to the execution of the weak action b is quite similar except for the inhibitor arc that prevents its firing if the strong action a has not be fired. The case in which c is fired when a has not, is modelled by the transition  $\langle c, a, 1 \rangle$ , that basically accounts for the execution of c followed by a move of the bond from the weak action c to a, which produces effects analogous to the execution of a. Finally, the transition  $\langle b, 0 \rangle$  corresponds to the execution of the weak prefix b, which is prevented if some of the actions in the strong part of the prefix (i.e., a and c) has not yet been executed.

**Lemma 4.** Let (s; b) be a CCB prefix. Then the LIPT  $(S, T, F, I, \ell)$  where

• 
$$S = \{ * \langle \mathbf{a}, i \rangle, \langle \mathbf{a}, i \rangle^{\dagger}, \langle \mathbf{a}, i \rangle^{\dagger} \mid \mathbf{a} \in S \land 1 \le i \le s(\mathbf{a}) \} \cup \{ * \langle c, 1 \rangle, \langle c, 1 \rangle^{\dagger}, \langle c, 1 \rangle^{\dagger} \mid c \in \mathcal{W} \cap s \} \cup \{ * \langle b, 0 \rangle, \langle b, 0 \rangle^{\dagger} \};$$

•  $T = T_{STR_s} \cup T_{STR_w} \cup T_{STR_m} \cup T_{WK};$ 

•  $F = F_{\text{STR}_s} \cup F_{\text{STR}_w} \cup F_{\text{STR}_m} \cup F_{\text{WK}};$ 

•  $I = I_{STR_w} \cup I_{STR_m} \cup I_{WK}$ ; and

•  $\ell = \ell_{\text{STR}_{\text{S}}} \cup \ell_{\text{STR}_{\text{W}}} \cup \ell_{\text{STR}_{m}} \cup \ell_{\text{WK}}$ 

is а свн.

**Proof.** To prove that the net the LIPT  $N = \langle S, T, F, I, \ell \rangle$  is indeed a CBNit is enough to show that it is a pBN.

We first observe that weak(N) = { $\langle b, 0 \rangle$ } and its inhibitor set  $\circ \langle b, 0 \rangle$  is { $* \langle a, i \rangle | a \in S \land 1 \le i \le s(a)$ }  $\cup {* \langle c, 1 \rangle}$ . Each transition in  $T_{STR_s} \cup T_{STR_w} \cup T_{STR_w} \cup T_{WK}$  has just a place in their pre set, and two transition sharing the pre set are equally labelled. Each transition in  $T_{STR_s} \cup T_{STR_w} \cup T_{WK}$  has an empty inhibitor set, and finally each transition  $t \in T_{STR_s} \cup T_{STR_w} \cup T_{WK}$  has a key place. Therefore N is indeed a pBN.  $\Box$ 

**Example 18.** Consider the CBN depicted in Fig. 17, the initial marking has places  $\langle a, 1 \rangle$ ,  $\langle c, 1 \rangle$  and  $\langle b, 0 \rangle$  marked as in (a, c; b) none of the action has been executed. The execution of the strong action a leads to removing the token from place  $\langle a, 1 \rangle$ , marking the places  $\langle a, 1 \rangle^*$  and  $\langle a, 1 \rangle^{\dagger}$ . This correspond to (a[k], c; b) where *k* correspond uniquely to  $\langle a, 1 \rangle^{\dagger}$ .

So far we have considered just the transitions performing *forward* actions, beside the move actions, where a weak action is executed and it is reversed and its key is moved to a strong action, which will result as performed though its key is invalidated. We now focus on the encoding of transitions corresponding to *reverse* actions. We start from rule <u>STR</u> obtaining the set of transitions

$$T_{\text{STR}}(s; b) = \{ \langle \underline{a}, i \rangle \mid a \in \mathcal{A} \land 1 \le i \le s(a) \}$$

The definitions of the pre and post sets are as expected.

• $\langle a, i \rangle = \{ \langle a, i \rangle^*, \langle a, i \rangle^\dagger \} \quad \langle a, i \rangle^\bullet = \{ * \langle a, i \rangle \}$ 

The inhibitor arc just checks that the reversal without move can only proceed only if no weak action has been executed as part of either the strong or the weak prefix, i.e.,

$$^{\circ}\langle \mathsf{a},i\rangle = \{\langle c,1\rangle^* \mid c \in \mathcal{W} \cap s\} \cup \{\langle b,0\rangle^*\}$$

<sup>60</sup> Labels keep track of the performed reverse action, i.e.,  $\ell \langle \underline{a}, i \rangle = \underline{a}$ .  $F_{\underline{STR}}$  and  $I_{\underline{STR}}$  are the flow arcs and inhibitor arcs for these <sup>61</sup> transitions,  $\ell_{\underline{STR}}$  the labelling mapping.

 $(b, 0)^{3}$ 

[m3G; v1.312] P.19 (1-31)

 $T_{\underline{STR}}(\mathbf{a}, c; b) = \{ \langle \underline{\mathbf{a}}, 1 \rangle, \langle \underline{c}, 1 \rangle \}$   $T_{\underline{STR}_p}(\mathbf{a}, c; b) = \{ \langle \underline{\mathbf{a}}, i, (b) \rangle \}$  $T_{STR_m}(\mathbf{a}, c; b) = \{ \langle \underline{\mathbf{a}}, i, c \rangle \}$ 

(a, 1, (b))  $(a, 1)^{+}$   $(a, 1)^{+}$   $(a, 1)^{+}$   $(a, 1)^{+}$   $(c, 1)^{+}$   $(c, 1)^{+}$   $(c, 1)^{+}$   $(c, 1)^{+}$ 

**Fig. 18.** Backward transitions for the encoding of (a, c; b).

The transitions of the reversal of a strong action combined with a promotion and a move discriminate situations in which the key that is being promoted or moved is not bound anywhere else in the system from the cases in which the key appears within other parallel process.

The transitions associated with the rule  $\underline{STR}_p$ , i.e., a reversal followed by a promotion, are of the kind  $(\underline{a}, i, (b))$  and they stand for the cases in which the promoted key is free while (the other cases are handled by concert rules, which will be described when encoding the composition). Henceforth we have

 $T_{\underline{STR}_n}(s; b) = \{ \langle \underline{a}, i, (b) \rangle \mid 1 \le i \le s(a) \}$ 

and the pre sets, post sets and inhibitor sets are as follows

$$^{\bullet}\langle \underline{\mathbf{a}}, i, (b) \rangle = \{ \langle \underline{\mathbf{a}}, i \rangle^{\dagger}, \langle b, 0 \rangle^{*}, \langle \underline{b}, 0 \rangle^{\dagger} \} \quad \langle \underline{\mathbf{a}}, i, (b) \rangle^{\bullet} = \{ ^{*}\langle b, 0 \rangle \} \quad ^{\circ}\langle \underline{\mathbf{a}}, i, (b) \rangle = \emptyset$$

Recall that the key of *b* is promoted to an invalid key of a, and for this reason there is no key place in the post set of this transition, and the key in a is removed. In this case, labels record the reversed action, i.e.,  $\ell(\underline{a}, i, (b)) = \underline{a}$ .  $F_{\underline{STR}_p}$  and  $I_{\underline{STR}_p}$  are the flow arcs and inhibitor arcs for these transitions,  $\ell_{\underline{STR}_p}$  the labelling mapping.

The last case, in which the reversal of a strong action is combined with a move is defined analogously, the only difference being that the key moved is the one of *c*, which is in the pre set of these transitions.

$$T_{\text{STR}_{m}}(s; b) = \{ \langle \underline{a}, i, c \rangle \mid a \in S \land 1 \le i \le s(a) \land c \in W \cap s \}$$

The post sets, pre sets and inhibitor sets are

• $\langle \underline{a}, i, c \rangle = \{ \langle \underline{a}, i \rangle^{\dagger}, \langle c, 1 \rangle^{*}, \langle c, 1 \rangle^{\dagger} \}$   $\langle \underline{a}, i, c \rangle^{\bullet} = \{ * \langle c, 1 \rangle \}$  ° $\langle \underline{a}, i, c \rangle = \{ \langle b, 0 \rangle^{*} \}$ 

The inhibitor arc is used to give priority to the promotion over the move. Also in this case, labels record the reversed action, i.e.,  $\langle \underline{c}, \underline{a}, i \rangle = \underline{a}$ .  $F_{\underline{STR}_m}$  and  $I_{\underline{STR}_m}$  are the flow arcs and inhibitor arcs for these transitions,  $\ell_{\underline{STR}_m}$  the labelling mapping.

**Example 19.** Consider the prefix (a, c; b) introduced in Example 17. The transitions corresponding to reverse actions are shown in Fig. 18. The reversal of the weak action c in the strong part of a prefix is described by the transition (c, 1) which consumes tokens from the places  $(c, 1)^*$  and  $(c, 1)^{\dagger}$  that respectively represent the execution of c and its key, and produce a token in the place (c, 1) that enables the execution of c. The remaining three transitions account for the reversal of the strong action a: the transition (a, 1) models the reversal of a when no successive promotion or move from a weak action is available (for this reason the transition is inhibited by the places  $(b, 0)^*$  and  $(c, 1)^*$ ), the transition  $(\underline{a}, 1, (b))$  represents the reversal of a followed by a promotion, and  $(\underline{a}, 1, c)$  the reversal of a followed by a move. In the case the promotion or the move is done, it should be noticed that despite the action a is undone, a promotion moves the key from the weak b to the action a (or from the weak c to the action a), consequently, after reversing a, b (or c) becomes enabled and a remains as executed. The reason why the transition consumes and reads the key  $(a, 1)^{T}$  is instrumental for the encoding of the parallel composition, as it will be clear later on. In the case of  $(\underline{a}, 1, c)$ , the inhibitor arc originated in  $(b, 0)^*$  states that promotion has priority over moves.<sup>1</sup> 

**Lemma 5.** Let (s; b) be a CCB prefix. Then the LIPT  $(S, T, F, I, \ell)$  where

• 
$$S = \{ * \langle \mathbf{a}, i \rangle, \langle \mathbf{a}, i \rangle^*, \langle \mathbf{a}, i \rangle^\dagger \mid \mathbf{a} \in S \land 1 \le i \le s(\mathbf{a}) \} \cup \{ * \langle c, 1 \rangle, \langle c, 1 \rangle^*, \langle c, 1 \rangle^\dagger \mid c \in W \cap s \} \cup \{ * \langle b, 0 \rangle, \langle b, 0 \rangle^*, \langle b, 0 \rangle^\dagger \};$$

<sup>&</sup>lt;sup>1</sup> In original CCB moves are not allowed if a prefix has a weak part.

a

**Fig. 19.** The net corresponding to the prefix (a, c; b) with forward and reverse transitions.

- T = T<sub>STRs</sub> ∪ T<sub>STRw</sub> ∪ T<sub>STRm</sub> ∪ T<sub>WK</sub> ∪ T<sub>STR</sub> ∪ T<sub>STR</sub> ∪ T<sub>STR</sub>;
   F = F<sub>STRs</sub> ∪ F<sub>STR</sub> ∪ F<sub>STR</sub> ∪ F<sub>WK</sub> ∪ F<sub>STR</sub> ∪ F<sub>STR</sub> ∪ F<sub>STR</sub>;
- $I = I_{STR_w} \cup I_{STR_m} \cup I_{WK} \cup I_{STR} \cup I_{STR_m}$ , and
- $\ell = \ell_{\text{STR}_s} \cup \ell_{\text{STR}_w} \cup \ell_{\text{STR}_m} \cup \ell_{\text{WK}} \cup \ell_{\underline{\text{STR}}} \cup \ell_{\underline{\text{STR}}_n} \cup \ell_{\underline{\text{STR}}_n}$

### is a CBN.

Δ

**Proof.** We have already seen in Lemma 4 that if we focus on the transitions in  $T = T_{STR_s} \cup T_{STR_w} \cup T_{STR_w} \cup T_{WK}$  we have an CBN. The transitions in  $T_{STR} \cup T_{STR_n} \cup T_{STR_m}$  are such that they consume tokens from at least a key place, hence these transitions are in U. For each transition in  $t \in T_{STR_s} \cup T_{STR_w}$  there is just a transition in  $u \in T_{STR_s} \cup T_{STR_w}$  such that  $\bullet u = t^{\bullet}$ ,  $u^{\bullet} = {}^{\bullet}t$  and  $\ell(t) = \ell(u)$  as required. Hence the net is a CBN.  $\Box$ 

**Example 20.** In the Fig. 19 the nets depicted in Fig. 17 and Fig. 18 are put together. At the beginning the places (a, 1), (c, 1) and (b, 0) are marked. The execution of (a, 1) will remove the token from (a, 1) putting it in  $(a, 1)^*$ and  $(a, 1)^{\dagger}$ . At this feasible marking we can reverse the last executed transition obtaining the initial marking or we can execute the action  $c(\langle c, 1 \rangle)$  marking  $\langle c, 1 \rangle^*$  and  $\langle c, 1 \rangle^{\dagger}$  and after a move executing  $\langle \underline{a}, 1, c \rangle$  has the effect of moving the key of c to a, which will have a invalid key (the place  $(a, 1)^*$  is marked but  $(a, 1)^{\dagger}$  is not).

In what follows we discuss the set of transitions corresponding to concert rules  $A-WK_1$ ,  $A-WK_2$  and  $A-WK_3$ . The set of transitions induced by the rule A-WK1 is

$$T_{\text{A-WK1}}(s; b) = \{ \langle (b), a, i \rangle \mid a \in S \land 1 \le i \le s(a) \}$$

The inhibitor arcs for these transitions are as follows

$$^{\circ}\langle (b), \underline{a}, i \rangle = \{^{*} \langle c, j \rangle \mid 1 \leq j \leq s(c)\} \cup \{\langle b, 0 \rangle^{*}\}$$

to account for the fact that the weak prefix cannot be executed until all actions in the strong part of a prefix have been executed. The pre and post sets capture the idea that the original key associated with a is released and a becomes now associated with the bond generated by the weak prefix, i.e.,

• $\langle (b), \mathbf{a}, i \rangle = \{ \langle \mathbf{a}, i \rangle^{\dagger} \} \langle (b), \mathbf{a}, i \rangle^{\bullet} = \emptyset$ 

The associated label records both the forward and backward actions,  $\ell((b), \underline{a}, i) = (b), \underline{a}$ . Again we denote these sets and the labelling mapping with  $F_{A-WK_1}$ ,  $I_{A-WK_1}$  and  $\ell_{A-WK_1}$ .

The transitions associated with A-WK2 are

$$T_{\text{A-WK}_2}(s; b) = \{ \langle c, a, i \rangle \mid a \in S \land 1 \le i \le s(a) \land c \in W \cap s \}$$

and the pre and post set are analogous to the previous case

• 
$$\langle c, \underline{a}, i \rangle = \{ \langle \underline{a}, i \rangle^{\dagger} \} \quad \langle c, \underline{a}, i \rangle^{\bullet} = \emptyset \quad \circ \langle c, \underline{a}, i \rangle = \{ \langle b, 1 \rangle^{*} \}$$

The inhibitor arc for each transition just checks that c has not been executed. In this case labels record that the execution of the weak forward action and the reverse strong action in the strong part of a prefix, i.e.,  $\ell(c, \underline{a}, i) = \langle c \rangle, \underline{a}, F_{A-WK_1}, I_{A-WK_1}$ and  $\ell_{A-WK_1}$  are the flow and inhibitor arcs as well as the labelling mapping.

**Fig. 20.** Concerted transitions for the encoding of (a, c; b).

Finally the transitions for  $A-WK_3$  do the same work, but involve three actions. They are defined as

 $T_{A-WK_2}(s; b) = \{ \langle c, a, i, d, j \rangle \mid a, d \in S \land 1 \le i \le s(a) \land 1 \le j \le s(d) \land c \in W \cap s \}$ 

The inhibitor arc for each transition ensures that *c* has not been executed.

 $^{\circ}\langle c, \mathbf{a}, i, \mathbf{d}, j \rangle = \{\langle c, 1 \rangle^*\}$ 

The pre and post set rearrange the markings to reverse a and invalidate d by associating the key borrowed from c.

•  $(c, a, i, d, i) = \{(a, i)^*, (a, i)^{\dagger}, *(d, i)\}$   $(c, a, i, d, i)^{\bullet} = \{*(a, i), (d, i)^*\}$ 

Labels are as before  $\ell(c, \underline{a}, i, d, j) = \langle c \rangle$ ,  $\underline{a}$ . Arcs and labelling are  $F_{A-WK_3}$ ,  $I_{A-WK_3}$  and  $\ell_{A-WK_3}$ .

**Example 21.** Consider the prefix (a, c; b) introduced in Example 17. The transitions corresponding to concert actions are shown in Fig. 20. Transition  $\langle (b), a, i \rangle$  accounts for a prefix contributing with the reversal of a and the forward weak action in a weak prefix, i.e., (b). It should be noted that this transition can be applied only if the weak prefix has not been executed (i.e., inhibitor arc from  $(b, 0)^*$ ) and no action in the strong part of a prefix is still unexecuted (i.e., the inhibitor arcs \*(a, 1)and (c, 1). Note that the bond created by the weak action will be promoted to the just reversed action. For this reason, the firing of the transition just consumes the key  $\langle a, i \rangle^{T}$  the marking; as before the apparently, superfluous consume/produce loop on the key is instrumental for the encoding of parallel composition. The transition  $\langle c, a, i \rangle$  corresponds to a prefix contributing with a forward weak action in strong position (*i.e.*,  $\langle c \rangle$ ) and the reverse of a. The reversal of the weak action c in the strong part of a prefix is described by the transition (c, 1) and its definition is analogous.

**Lemma 6.** Let (s; b) be a CCB prefix. Then the LIPT  $(S, T, F, I, \ell)$  where

- $S = \{ \langle a, i \rangle, \langle a, i \rangle^*, \langle a, i \rangle^\dagger \mid a \in S \land 1 \le i \le s(a) \} \cup \{ \langle c, 1 \rangle, \langle c, 1 \rangle^*, \langle c, 1 \rangle^\dagger \mid c \in W \cap s \} \cup \{ \langle b, 0 \rangle, \langle b, 0 \rangle^*, \langle b, 0 \rangle^\dagger \}$
- $T = T_{STR_s} \cup T_{STR_w} \cup T_{STR_m} \cup T_{WK} \cup T_{\underline{STR}} \cup T_{\underline{STR}_p} \cup T_{\underline{STR}_m} \cup T_{A-WK_1} \cup T_{A-WK_2} \cup T_{A-WK_3};$   $F = F_{STR_s} \cup F_{STR_w} \cup F_{STR_m} \cup F_{WK} \cup F_{\underline{STR}} \cup F_{\underline{STR}_p} \cup F_{\underline{STR}_m} \cup F_{A-WK_1} \cup F_{A-WK_2} \cup F_{A-WK_3};$

- $I = I_{STR_w} \cup I_{STR_m} \cup I_{WK} \cup I_{\underline{STR}} \cup I_{\underline{STR}_m} \cup I_{A-WK_1} \cup I_{A-WK_2} \cup I_{A-WK_3}$ , and  $\ell = \ell_{STR_s} \cup \ell_{STR_w} \cup \ell_{STR_m} \cup \ell_{WK} \cup \ell_{\underline{STR}} \cup \ell_{\underline{STR}_p} \cup \ell_{\underline{STR}_m} \cup \ell_{A-WK_1} \cup \ell_{A-WK_3} \cup \ell_{A-WK_3}$

is a CBN.

**Proof.** We have already seen in Lemma 5 that if we focus on the transitions in  $T_{STR_s} \cup T_{STR_m} \cup T_{STR_m} \cup T_{MK} \cup T_{STR} \cup T_{STR_n} \cup T_{STR_m} \cup T$  $T_{\text{STR}_{m}}$  we have an CBN. The new added transitions manipulate basically keys, hence are in U and are no counterpart of any strong or weak transition. The thesis follows.  $\Box$ 

We now put together all the pieces we have collected so far. We write Rules for the set of the names of rules associated with prefixes, i.e.,

 $Rules = \{STR_s, STR_w, STR_m, WK, \underline{STR}, \underline{STR}, \underline{STR}, \underline{STR}, A-WK_1, A-WK_2, A-WK_3\}$ 

**Definition 22.** The net  $\mathcal{N}(s; b) = \langle S, T, F, I, \ell \rangle$  is the net associated to the prefix (s; b), where

• 
$$S = \{ *\langle a, i \rangle, \langle a, i \rangle^{\dagger}, \langle a, i \rangle^{\dagger} \mid a \in S \land 1 \leq i \leq s(a) \} \cup \{ *\langle c, 1 \rangle, \langle c, 1 \rangle^{\dagger}, \langle c, 1 \rangle^{\dagger} \mid c \in W \cap s \} \cup \{ *\langle b, 0 \rangle, \langle b, 0 \rangle^{\dagger}, \langle b, 0 \rangle^{\dagger} \};$$

• 
$$T = \bigcup_{r \in \mathsf{Bules}} T_r(s; b),$$

- $F = \bigcup_{r \in \text{Bules}} F_r(s; b);$
- $I = \bigcup_{r \in \text{Bules}} I_r(s; b)$ ; and

**Fig. 21.** The overall net of (a, *c*; *b*).

•  $\ell = \bigcup_{r \in \mathsf{Bules}} \ell_r(s; b).$ 

**Lemma 7.** Let (s; b) be a prefix. Then the net  $\mathcal{N}((s; b))$  is a CBN.

**Proof.** By putting together the proofs of Lemma 4, Lemma 5 and Lemma 6.  $\Box$ 

We discuss now how to associate the marking  $\mathcal{M}((s; b))$  to the prefix  $(s; \beta)$  in the net  $\mathcal{N}((s; b))$  where possibly  $\beta = b[l]$  for some key l and some of the action in s may have a key k or an invalid key  $\dagger l$ . To ease the notation we write s as  $s_1 + s_2 + s_3$  where  $s_1$  are the unexecuted actions,  $s_2$  are the actions with non-invalidated keys, and  $s_3$  actions with invalidated keys ( $\dagger$ ). Therefore  $s_1 \in \mathbb{N}^{\mathcal{A}}$ ,  $s_2 \in \mathbb{N}^{\mathcal{A} \times \mathcal{K}}$  which is a set and  $s_3 \in \mathbb{N}^{\mathcal{A} \times \dagger \mathcal{K}}$  which is again set. Finally, given  $t \in \mathbb{N}^{\mathcal{A} \times \mathcal{K}}$  (or  $t \in \mathbb{N}^{\mathcal{A} \times \dagger \mathcal{K}}$ ), with  $\tilde{t}$  we denote the multiset in  $\mathbb{N}^{\mathcal{A}}$  defined as  $\tilde{t}(a) = \sum_{k \in \mathcal{K}} t(a, k)$ .

The marking (we indicate only the marked places) is then

$$\mathcal{M}((s;\beta)) = \{ {}^{*}\langle \mathbf{a}, i \rangle \mid 1 \le i \le s_{1}(\mathbf{a}) \land \mathbf{a} \in \mathcal{A} \}$$
$$= \cup \{ \langle \mathbf{a}, i \rangle^{*}, \langle \mathbf{a}, i \rangle^{\dagger} \mid s_{1}(\mathbf{a}) < i \le s_{1}(\mathbf{a}) + \tilde{s_{2}}(\mathbf{a}) \land \mathbf{a} \in \mathcal{A} \}$$
$$= \cup \{ \langle \mathbf{a}, i \rangle^{*} \mid s_{1}(\mathbf{a}) + \tilde{s_{2}}(\mathbf{a}) < i \le s_{1}(\mathbf{a}) + \tilde{s_{2}}(\mathbf{a}) + \tilde{s_{3}}(\mathbf{a}) \}$$
$$= \cup \{ {}^{*}\langle b, 0 \rangle \mid \beta = b \} \cup \{ \langle b, 0 \rangle^{*}, \langle b, 0 \rangle^{\dagger} \mid \beta = (b, l) \}$$

Observe that the transitions  $\langle a, i \rangle$  corresponding to an a with an invalidated key has no token in the key place  $\langle a, i \rangle^{\dagger}$ . Hereafter, we will consider nets up-to permutation of natural numbers.

**Example 22.** Consider the prefix (a, *c*; *b*) introduced in Example 17. The net representing all the forward (see Fig. 17), backward (see Fig. 18) and concert (see Fig. 20) transitions is depicted in Fig. 21.

 $\mathcal{M}((a, c; b))$  is such that (a, 1), (c, 1) and (b, 0) are marked and all the other places do not have any token.  $\mathcal{M}((a[1], c; b))$  is, instead of, such that  $(a, 1)^*$ ,  $(a, 1)^{\dagger}$ , (c, 1) and (b, 0) are marked, and the other places are unmarked, and  $\mathcal{M}((a[\dagger 1], c; b))$  has the places  $(a, 1)^*$ , (c, 1) and (b, 0) marked.

The encoding of a prefixed process (s; b).<sup>S</sup> is obtained as the disjoint union of the nets encoding the prefix (s; b) and the continuation <sup>S</sup> with the addition of the inhibitor arcs that prevent the execution of forward actions in <sup>S</sup> and reverse actions of (s; b) as appropriate.

**Definition 23.** Let  $N = \langle S, T, F, I, \ell \rangle$  be a CBN such that  $|\mathcal{Y}| = 1$ . Then  $\min_{\mathcal{S}}(N) = \{t \in T \mid t \in T_{\mathcal{C}(N,1)} \setminus \text{weak}(\mathcal{C}(N,1)) \land \ell(t) \in \mathcal{A}\}$  is the set of minimal strong transitions of N and  $\min_{\mathcal{W}}(N) = \text{weak}(\mathcal{C}(N,1))$ .

The idea is that  $\min_{\mathcal{S}}(N)$  are the first transitions that have to be executed in a CBN with just one component, which accounts to say that the CBN is a well-stratified one and  $\min_{\mathcal{W}}(N)$  contains the unique weak transition of  $\mathcal{C}(N, 1)$ .

**Proposition 5.** Let  $N = \mathcal{N}(s; b)$  be the CBN associated to the prefix (s; b). Then  $\min_{\mathcal{S}}(N) = T_{STR_s} \cup T_{STR_w}$  is the set of minimal strong transitions of N, and  $\min_{\mathcal{W}}(N) = T_{WK}$ .

**Proof.** *N* is a CBN and  $\mathcal{Y}$  contains just one index. The transitions in  $\min_{\mathcal{S}}(N)$  are precisely those with a label in  $\mathcal{A}$  and that are not a weak transition, and  $\min_{\mathcal{W}}(N)$  is the unique weak transition.  $\Box$ 

[m3G; v1.312] P.23 (1-31) Theoretical Computer Science ••• (••••) •••-•••

Fig. 22. The net  $\mathcal{N}((a, c; b).(d; e))$  without the reversing, the move, the promotions and the concerting transitions.

### With the aid of the notions of minimal transitions we can state what is the encoding of the CCB process (s; b).S.

**Definition 24.** Let (s; b). S be a CCB process,  $\mathcal{N}(S) = \langle S_S, T_S, F_S, I_S, \ell_S \rangle$  and  $\mathcal{N}(s; b) = \langle S_{(s;b)}, T_{(s;b)}, F_{(s;b)}, \ell_{(s;b)} \rangle$  be the nets associated with S and  $\mathcal{N}(s; b)$ . Then,  $\mathcal{N}((s; b), S)$  is the net defined as

- $S_{(s;b),P} = S_{S} \uplus S_{(s;b)};$
- $T_{(s;b),P} = T_{\mathbf{S}} \uplus T_{(s;b)};$
- $F_{(s;b),P} = F_{\mathbf{S}} \uplus F_{(s;b)};$
- $I_{(s;b),P} = I_{\mathbb{S}} \uplus I_{(s;b)} \cup Fw \cup Bw$ , where  $Fw = (\{ (a, i) \in S_{(s;b)} \} \cup \{ (b, 0)^* \}) \times \min_{\mathbb{S}}(\mathbb{N}(\mathbb{S}))$  and  $Bw = \min_{\mathbb{S}}(\mathbb{N}(\mathbb{S}))^{\bullet} \times T_{(s;b)};$ and
- $\ell_{(s;b),s} = \ell_s \uplus \ell_{(s;b)}$ .

The causal constraints imposed by the prefix operator are captured by the inhibitor arcs in Fw and Bw. The set Fw gives the constraints for the forward execution. Intuitively, a forward transition (c, i) in  $\mathcal{N}(S)$  that is initially enabled (i.e.,  $(c, i) \in \min_{S}(\mathcal{N}(S)))$  is inhibited because either (i) an action a in the strong part of the prefix s has not be fired (i.e., a place (a, i) is marked) or (ii) the weak prefix b has been already fired (i.e.,  $(b, 0)^*$  is marked). The constraints for reversibility are stated by Bw, and basically says that any transition t of the prefix is inhibited if any action in the continuation has been executed, i.e., a place in the post set of some of the minimal transitions in  $\mathcal{N}(P)$  is marked.

**Example 23.** In Fig. 22 the forward transitions of the term (a, c; b).(d; e) are depicted, highlighting how the two components, the one corresponding to (a, c; b) and the other to (d; e) are connected with the inhibitor arcs. It should be stressed that all the other transitions of (a, c; b) are inhibited when one of (d; e) is executed.

**Lemma 8.** The net  $\mathcal{N}(S)$  is an CBN.

**Proof.** The proof is by induction on the structure of S. We prove that the net is a CBN and it has just one component. If S is 0 then the thesis follows Consider S as (s; b). S' and by inductive hypothesis that  $\mathcal{N}(S')$  is a CBN and it is such that  $\mathcal{Y}$  has just one element  $\mathcal{N}(S')$  is a well-stratified pbn. Then  $\mathcal{N}((s; b), S')$  is by construction a well-stratified pbn, and then it is a CBN as required.

The marking associated to (s;  $\beta$ ). S, where again  $\beta = b[l]$  for some key l and some of the action in s may have a key k or an invalid key  $\dagger l$ , is then the union of  $\mathcal{M}((s; \beta))$  and  $\mathcal{M}(s)$  which is well defined as the places of the net are disjoint.

**Example 24.** Consider the net partially shown in Fig. 22 where just the forward transitions of (a, c; b).(d; e) are shown, and consider (a[1], c[2]; b).(d[3]; e). In this case the marked places are  $\langle b, 0 \rangle$ ,  $\langle e, 0 \rangle$ ,  $\langle a, 1 \rangle^*$ ,  $\langle c, 1 \rangle^*$ ,  $\langle d, 1 \rangle^*$ ,  $\langle a, 1 \rangle^T$ ,  $\langle c, 1 \rangle^T$ and  $(d, 1)^T$ .

It should be underlined that std(S) is defined by considering all the places of the kind  $\langle x, i \rangle$  marked in  $\mathcal{M}(S)$ , where x is the name of an action and this gives a straightforward implementation of the predicate *std*(S). It remains to discuss how

ARTICLE IN PRESS		
		F S S

the rules for composition of CCB terms are encoded. We write  $\gamma(t_1, t_2)$  in lieu of  $\gamma(\ell(t_1), \ell(t_2))$ . Given two disjoint nets  $N_1$  and  $N_2$  defined as  $N_i = \langle S_i, T_i, F_i, I_i, \ell_i \rangle$ , we write  $(N_1 || N_2)$  for the set of transitions for forward synchronisations, aka bonds, is defined as

$$T_{(N_1 || N_2)} = \{ \langle t_1 || t_2 \rangle \mid t_1 \in T_1 \land t_2 \in T_2 \land \gamma(t_1, t_2) \downarrow \}$$

The function  $bk(_)$  takes a place, an action and a possible synchronisation (bond) and gives a new key place stating that the synchronisation (bond) has been executed and the place concerns that action, and otherwise it gives the place it received in input:

$$\mathsf{bk}(p, \mathbf{a}, \alpha) = \begin{cases} \alpha \langle \mathbf{a}, i \rangle^{\dagger} & \text{if } p = \langle \underline{\mathbf{a}}, i \rangle^{\dagger} \land i > 0 \\ p & \text{otherwise} \end{cases}$$

This mapping transforms a key  $\langle \underline{a}, i \rangle^{\dagger}$  (representing an unbound key) by another one  $\alpha \langle \underline{a}, i \rangle^{\dagger}$  representing a fresh key for the action a generated by the synchonisation  $\alpha$ . We also use bk(\_) for its obvious extension to set of places.

Therefore, taking the bond  $\langle t_1 || t_2 \rangle \in T_{(N_1 || N_2)}$  we connect it to the places in  $N_1$  and  $N_2$  as follows:

Every transition  $t_1 || t_2$  represents the synchronisation of two forward actions, one from each net. It basically describes the jointly execution of the two transitions. For this reason, the pre, post and inhibitor set roughly corresponds to the union of the respective set, with the amendment of generating a new pair of keys, i.e., if  $\langle a, j \rangle^{\dagger} \in t_i^{\bullet}$ , with  $i \in \{1, 2\}$  that key is represented by  $(t_1 || t_2) \langle a, j \rangle^{\dagger}$ . In this way we will distinguish among the concurrent execution of  $t_1$  and  $t_2$  from their synchronised execution  $t_1 || t_2$  by associating a different keys of one with respect to the other.

**Example 25.** Consider  $S_i = (a_i, c_i; b_i)$  for i = 1, 2 and assume a synchronisation algebra  $\gamma$ , defined such that  $\gamma(a_1, a_2) = a$ ,  $\gamma(b_1, b_2) = b$  and  $\gamma(c_1, c_2) = c$ . Let  $N_i = \mathcal{N}(S_i)$ , which are isomorphic to  $\mathcal{N}((a, c; b))$  in the Example 17. Then,

$$T_{(N_1 \parallel N_2)} = \{ \langle \langle \mathsf{a}_1, 1 \rangle \parallel \langle \mathsf{a}_2, 1 \rangle \rangle, \langle \langle \mathsf{c}_1, 1 \rangle \parallel \langle \mathsf{c}_2, 1 \rangle \rangle, \langle \langle \mathsf{c}_1, 1 \rangle \parallel \langle \mathsf{c}_2, \mathsf{a}_2, 1 \rangle \rangle, \langle \langle \mathsf{c}_1, \mathsf{a}_1, 1 \rangle \parallel \langle \mathsf{c}_2, 1 \rangle \rangle \}$$

we use to keys for this transitions, one to be use to promote on the left and on other on the right.

$$\alpha = \langle \langle a_{1}, 1 \rangle \| \langle a_{2}, 1 \rangle \rangle : \qquad ^{\bullet} \alpha = \{^{*} \langle a_{1}, 1 \rangle, ^{*} \langle a_{2}, 1 \rangle \}$$

$$\alpha^{\bullet} = \{ \langle a_{1}, 1 \rangle^{*}, \langle a_{2}, 1 \rangle^{*}, \alpha \langle a_{1}, 1 \rangle^{\dagger}, \alpha \langle a_{2}, 1 \rangle^{\dagger} \}$$

$$\alpha^{\bullet} = \{ \langle a_{1}, 1 \rangle, ^{*} \langle a_{2}, 1 \rangle, ^{*} \langle a_{2}, 1 \rangle^{\dagger} \}$$

$$\alpha^{\bullet} = \{ \langle c_{1}, 1 \rangle, ^{*} \langle c_{2}, 1 \rangle \}$$

$$\alpha^{\bullet} = \{ \langle c_{1}, 1 \rangle, ^{*} \langle c_{2}, 1 \rangle, ^{*} \langle \alpha \langle c_{1}, 1 \rangle^{\dagger}, \alpha \langle c_{2}, 1 \rangle^{\dagger} \}$$

$$\alpha^{\bullet} = \{ \langle c_{1}, 1 \rangle, ^{*} \langle a_{2}, 1 \rangle \}$$

$$\alpha = \{ \langle c_{1}, 1 \rangle \| \langle c_{2}, a_{2}, 1 \rangle \} : \qquad ^{\bullet} \alpha = \{ ^{*} \langle c_{1}, 1 \rangle, ^{*} \langle a_{2}, 1 \rangle \}$$

$$\alpha^{\bullet} = \{ \langle c_{1}, 1 \rangle, ^{*} \langle a_{2}, 1 \rangle \}$$

$$\alpha^{\bullet} = \{ \langle c_{1}, 1 \rangle, ^{*} \langle a_{2}, 1 \rangle \}$$

$$\alpha^{\bullet} = \{ \langle c_{1}, 1 \rangle, ^{*} \langle a_{2}, 1 \rangle \}$$

$$\alpha^{\bullet} = \{ \langle c_{1}, 1 \rangle, ^{*} \langle a_{2}, 1 \rangle \}$$

The last one, i.e.,  $(c_1, a_1, 1 \| c_2, 1)$  is defined analogously. The labelling of these transitions is

$$\ell \langle t \| t' \rangle = \gamma(t, t')$$

Fig. 23 illustrates the case for  $\langle \langle a_1, 1 \rangle \| \langle a_2, 1 \rangle \rangle$ . It should be noted that  $\langle \langle a_1, 1 \rangle \| \langle a_2, 1 \rangle \rangle$  produces in  $\alpha \langle a_1, 1 \rangle^{\dagger}$  and  $\alpha \langle a_2, 1 \rangle^{\dagger}$  instead of in  $\langle \underline{a}_1, 1 \rangle^{\dagger}$  and  $\langle \underline{a}_2, 1 \rangle^{\dagger}$ , as done by the transitions  $\langle a_1, 1 \rangle$  and  $\langle a_1, 2 \rangle$ . In this way, none of the reversing rules (Fig. 20) can be applied to undone  $a_1$  and  $a_2$  independently; they need to be reversed in a coordinated way, as will be described later.

The bk $(t, a, \alpha)$  used previously can be considered as a kind of *template* for the concerting rules (among those there are also the reversing ones), hence we define  $bt(t, a, \alpha)$  as the transition such that  ${}^{\bullet}bt(t, a, \alpha) = bk({}^{\bullet}t, a, \alpha), bt(t, a, \alpha)^{\bullet} =$  $bk(t^{\bullet}, a, \alpha)$  and  $bt(t, a, \alpha) = bk(t, a, \alpha)$ . This notation will help to define the templates for the concerted action. To un-derstand which templates should be considered, we need to understand which are the possible participants to a concerted action, which is the result of the concerted rule. Let t be a transition such that  $\langle \underline{a}, j \rangle^{\dagger} \in {}^{\bullet}t$ , all its versions that can be considered in concerting with respect to a set of synchronisation  $\mathbb{S}$  are the following: 

[m3G; v1.312] P.25 (1-31)

### Theoretical Computer Science ••• (••••) •••-•••

**Fig. 23.** Forward synchronisations of a in (a, c; b) || (a, c; b).

$$\operatorname{conc}(t, \mathbb{S}) = \mathbb{T}_1 \cup \mathbb{T}_2$$

where

∡

 $\mathbb{T}_1 = \{ \mathsf{bt}(t, \mathsf{a}, \alpha) \mid \langle \mathsf{a}, \mathsf{j} \rangle^{\dagger} \in {}^{\bullet}t \land \alpha \in \mathbb{S} \}$ 

$$\mathbb{T}_2 = \{ \mathsf{bt}(\mathsf{bt}(t, \mathsf{a}, \alpha), c, \beta) \mid \{ \langle \mathsf{a}, j \rangle^{\dagger}, \langle c, 1 \rangle^{\dagger} \} \subseteq {}^{\bullet}t \land \alpha, \beta \in \mathbb{S} \}$$

 $\operatorname{conc}(\cdot, \cdot)$  scales to subset of transitions:  $\operatorname{conc}(T, \mathbb{S}) = \bigcup_{t \in T} \operatorname{conc}(t, \mathbb{S})$ . The idea is that any transition in T gives place to another version of it in which the keys corresponds to some of the possible synchronisations in  $\mathbb{S}$  (the  $\mathbb{T}_1$  part) and the second one  $(\mathbb{T}_2)$  is for transitions  $\langle \underline{a}, i, c \rangle$ , which may have also a bounded key that will be invalidated. The set  $\operatorname{conc}(T, \mathbb{S})$  contains transitions that cannot be used, but they are sorted out when actually combining them in parallel (concerting them). For the time being, the set of candidate bonded synchronisations is:

$$T_1 \oplus T_2 = \{ \langle t_1 \oplus t_2 \rangle \mid t_1 \in \operatorname{conc}(T_1, T_1 || T_2) \land t_2 \in \operatorname{conc}(T_2, T_1 || T_2) \}$$

We will take pairs of transitions that require the same key. We say two transitions *t* and *t'* agree on the bounded keys for a and b, written  $t\{a = b\}t'$ , if and only if  $\exists \alpha, i, j.\alpha \langle \underline{a}, i \rangle^{\dagger} \in {}^{\bullet}t \land \alpha \langle \underline{b}, j \rangle^{\dagger} \in {}^{\bullet}t'$ , and the  $\alpha$  implies that they come from the same synchronization; We also say that *t* does not use a bond on a, written  $t\{\neq a\}$ , if does not use a bond key for it, i.e.,  $t\{\neq a\} \iff \neg \exists \alpha, i.\alpha \langle \underline{a}, i \rangle^{\dagger} \in {}^{\bullet}t$ .

We will use the labels to filter out the allowed combinations, and we obtain the following sets of concerting transitions, which contains also the standard reversing for bonds:

 $T_A = \{ \langle t_1 \oplus t_2 \rangle \mid \ell(t_1) = \underline{a} \land \ell(t_2) = \underline{b} \land t \{ a = b \} t' \land \gamma(a, b) \downarrow \}$  $T_B = \{ \langle t_1 \oplus t_2 \rangle \mid \ell(t_1) = \underline{a} \land \ell(t_2) = b \land t_1 \{ \neq a \} \land t_2 \{ \neq b \} \}$  $T_{\mathsf{C}} = \{ \langle t_1 \oplus t_2 \rangle \mid \ell(t_1) = \underline{\mathsf{a}}, (b) \land \ell(t_2) = \mathsf{c} \land t_1 \{ \neq \mathsf{a} \} \}$  $T_D = \{ \langle t_1 \oplus t_2 \rangle \mid \ell(t_1) = \underline{a}, (b) \land \ell(t_2) = \underline{d} \land t_1 \{ a = d \} t_2 \}$  $T_E = \{ \langle t_1 \oplus t_2 \rangle \mid \ell(t_1) = \underline{a}, \underline{d}, (b) \land \ell(t_2) \in \{c, c, \langle c \rangle\} \land \gamma(a, d) \downarrow, \gamma(b, c) \downarrow \}$  $T_F = \{ \langle t_1 \oplus t_2 \rangle \mid \ell(t_1) = \underline{a}, (b), \beta \land \beta \in \{c, c, \langle c \rangle\} \land \ell(t_2) = \underline{d} \land \gamma(a, d) \downarrow, \gamma(b, c) \downarrow \}$  $T_{G} = \{ \langle t_{1} \oplus t_{2} \rangle \mid \ell(t_{1}) = \underline{a}, (b) \land \ell(t_{2}) \in \underline{d}, \beta \land \beta \in \{c, c, \langle c \rangle\} \land \gamma(a, d) \downarrow, \gamma(b, c) \downarrow \}$ 

The above sets are related with the possible synchronisations involving reverse actions. As a matter of fact,  $T_A$  stands for the transitions corresponding to rule (<u>COM</u>), i.e., the synchronisation of reverse actions. All the remaining ones, correspond to rule (CONCERT PAR), and are associated with the definition of the operator  $\oplus$  on CCB labels. The sets  $T_B$ ,  $T_C$  and  $T_D$  corresponds respectively to the first three cases in the definition of  $\oplus$ , while the final three corresponds to the last case in the definition of  $\oplus$  (we have split the cases here for technical convenience).

Then, the set of reverse and concerted transitions is therefore

$$T_{(N_1||N_2)} = T_A \cup T_B \cup T_C \cup T_D \cup T_F \cup T_G \cup T_E$$

The set of transitions  $T_A$  contains the expected reverse of a bond transition, whereas the others cases contains the transitions needed for concerting.

In all cases, the pre sets and inhibitor arcs are straightforward, i.e.,

$${}^{\bullet}\langle t_1 \oplus t_2 \rangle = {}^{\bullet}t_1 \cup {}^{\bullet}t_2 \qquad {}^{\circ}\langle t_1 \oplus t_2 \rangle = {}^{\circ}t_1 \cup {}^{\circ}t_2$$

For the post sets, the only provision is the cases in which there exists c s.t.  $\langle \underline{c}, 1 \rangle^{\dagger} \in t_1^{\bullet} \cup t_2^{\bullet}$ . Consider  $(a[k]; c) \| (a[k]; d) \|$ (e[j], c; d) where each action synchronises with itself. A concert rule allows to reach  $(a[\dagger l]; c) \| (a; d) \| (e[j], c[l]; d)$ . Here the question is which key we should associate to the prefix c[l]. Since its not free, it cannot be reversed, hence we cannot mark  $\langle c, 1 \rangle^{\dagger}$ . For this reason, we consider a further key  $\varkappa \langle c, 1 \rangle^{\dagger}$  for every weak action in the strong part of the prefix. We can now establish the post sets of the transitions in

•  $I = I_1 \cup I_2 \cup I_{(N_1,N_2)} \cup I_{(N_1||N_2)} \cup I_{\varkappa(T_1 \cup T_2)}$ ; and

 $\alpha = \langle \langle a, 1 \rangle \| \langle b, 1 \rangle \rangle$

Theoretical Computer Science ••• (••••) •••-•••

•  $\ell = \ell_1 \cup \ell_2 \cup \ell_{(N_1 \parallel N_2)} \cup \ell_{\underline{(N_1 \parallel N_2)}} \cup \ell_{\varkappa(T_1 \cup T_2)}$ 

where  $S_{nk}$ ,  $F_{nk}$ ,  $I_{nk}$  and  $\ell_{nk}$ , with  $nk \in \{(N_1 || N_2), (N_1 || N_2), \varkappa(T_1 \cup T_2)\}$  are defined as illustrated above.

We have again an CBN, as shown by the following result.

**Lemma 9.** Let  $\mathbb{P}_1$  and  $\mathbb{P}_2$  be two CCB terms and  $\mathbb{N}(\mathbb{P}_1) = \langle S_i, T_i, F_i, I_i, \ell_i \rangle$  for i = 1, 2, the associated disjoint cBNs. Then  $\mathbb{N}(\mathbb{P}_1 || \mathbb{P}_2)$  is a cBN.

**Proof.** As  $\mathcal{N}(\mathbb{P}_1) = \langle S_i, T_i, F_i, I_i, \ell_i \rangle$  are CBNS, there exists for each a partition with  $\mathcal{Y}_i$  for i = 1, 2. Now, the only requirement to check is that if we are considering a bond between the two, there is one of the reversing bond. But this is clear by constructions (these are the transition in  $T_A$  above). The thesis follows.  $\Box$ 

The marking associated with  $\mathbb{P}_1 \| \mathbb{P}_2$  cannot be straightforwardly inferred from the markings  $\mathcal{M}(\mathbb{P}_1)$  because of the loose of information about keys. Consider the process  $(a[1]; b) \| (a[1]; c)$  and note that "1" is a shared key. If processes (a[1]; b)and (a[1]; c) are taken independently, such shared key would be considered as two different private ones; hence the two actions a would appear as executed independently. For this reason, we substitute shared keys in a parallel composition  $\mathbb{P}_1 \| \mathbb{P}_2$  by invalidated keys (recall that invalidated keys translates into unmarked key places). For each shared key, we record the transitions names. Then, for these pairs of names, we mark the key places of the synchronization. Given  $\mathbb{P}_1 \| \mathbb{P}_2$ ,  $\phi(\mathbb{P}_1 \| \mathbb{P}_2)$  gives the set of shared keys together with the names of the transitions in each of the nets  $\mathcal{N}(\mathbb{P}_1) \cap key(\mathbb{P}_2)$ the mapping returns the triple  $(k, t_1, t_2)$  where  $t_i$  are the transitions in  $\mathcal{N}(\mathbb{P}_1)$  which corresponds to the actions in  $\mathbb{P}_1$  and  $\alpha \langle \mathbf{b}, j \rangle^{\dagger}$ , where a and b are the actions with the same key and  $\alpha$  is  $\langle t_1 \| t_2 \rangle$ , which are the key places added by the various bonds. Thus  $\phi(\mathbb{P}_1 \| \mathbb{P}_2) = (\Omega, \mathbb{P}'_1 \| \mathbb{P}'_2)$  where  $\Omega$  is the set of triples and  $\widehat{\mathbb{P}_1} \| \widehat{\mathbb{P}_2}$  is the CCB term where the various shared keys have been invalidated. Hence when defining  $\mathcal{M}(\mathbb{P}_1 \| \mathbb{P}_2)$  we have  $\mathcal{M}(\widehat{\mathbb{P}_1}) \cup \mathcal{M}(\widehat{\mathbb{P}_2}) \cup \{\alpha(t_i)^{\dagger} \mid \exists (k, t_1, t_2) \in \Omega \land \alpha = t_1 \oplus t_2\}$ where  $(t_i)^{\dagger}$  is the key place associated to the transition  $t_i$  (Fig. 26).

**Example 28.** Consider  $(a[1]; c) \| (b[1]; d)$  and assume that  $\gamma$  on (a, b) is defined. Then  $\phi((a[1]; c) \| (b[1]; d))$  gives  $\Omega = \{(1, \langle a, 1 \rangle, \langle b, 1 \rangle\} \text{ and } (a[\dagger 1]; c) \| (b[\dagger 1]; d) \text{ and } \mathcal{M}((a[1]; c) \| (b[1]; d)) \text{ is } \mathcal{M}((a[\dagger 1]; c)) \cup \mathcal{M}((b[\dagger 1]; d)) \cup \{\alpha \langle a, 1 \rangle^{\dagger}, \alpha \langle b, 1 \rangle^{\dagger}\}.$ 

The last operation we have to encode is the restriction.

**Definition 26.** Let P be a CCB term and let  $\mathcal{N}(\mathbb{P}) = \langle S_{\mathbb{P}}, T_{\mathbb{P}}, F_{\mathbb{P}}, I_{\mathbb{P}}, \ell_{\mathbb{P}} \rangle$  be the associated CBN. Then  $\mathcal{N}(\mathbb{P} \setminus L)$  is the net  $\langle S, T, F, I, \ell \rangle$  where  $S = S_{\mathbb{P}} \uplus \{s_x \mid x \in L\}$ ,  $T = T_{\mathbb{P}}$ ,  $F = F_{\mathbb{P}}$ ,  $\ell = \ell_{\mathbb{P}}$  and  $I = I_{\mathbb{P}} \uplus \{(s_x, t) \mid x \in L \land \ell_{\mathbb{P}}(t) = x\}$ .

Obviously we have that the resulting construction is a CBN.

**Lemma 10.** Let  $\mathbb{P} \setminus L$  be a CCB term. Then  $\mathcal{N}(\mathbb{P} \setminus L)$  is a CBN.

The marking associated to the term  $\mathbb{P} \setminus L$  in the net  $\mathcal{N}(\mathbb{P} \setminus L)$  is  $\mathcal{M}(\mathbb{P})$ .

We can now put together what we have seen so far and we have the following result, which summarize that our encoding gives a covalent bond net.

**Theorem 1.** Let P be a CCB term, then  $\mathcal{N}(P)$  is a CBN.

|--|

JID:TCS AID:13224 /FLA Doctopic: Theory of natural computing H. Melgratti, C.A. Mezzina and G.M. Pinna

We prove now that our encoding is full and faithful, meaning that each move in the transition system associated to the CCB terms is matched by a fireable transition in the encoding of the term, and if one fires a transition in the net which encodes a CCB term, then the corresponding move can be performed also on the term.

We write  $\mu \equiv L$  if L is obtained by removing the keys in  $\mu$ . Moreover, we write  $\mathcal{N}(\mathbb{P}) \xrightarrow{L} \mathcal{N}(\mathbb{Q})$  if there exists a transition *t* with label L, *i.e.*,  $\ell(t) = L$  that is enabled at  $(\mathcal{N}(\mathbb{P}), \mathcal{M}(\mathbb{P}))$  and  $(\mathcal{N}(\mathbb{Q}), \mathcal{M}(\mathbb{Q}))$  is the result of firing *t* in  $(\mathcal{N}(\mathbb{P}), \mathcal{M}(\mathbb{P}))$ .

**Theorem 2.** *If* **P** *is well-formed then* 

1. if  $\mathbb{P} \xrightarrow{\mu} \mathbb{Q}$  then  $\mathcal{N}(\mathbb{P}) \xrightarrow{\mathsf{L}} \mathcal{N}(\mathbb{Q})$  and  $\mu \equiv \mathsf{L}$ ; and 2. if  $\mathcal{N}(\mathbb{P}) \xrightarrow{\mathsf{L}} (N, \mathsf{m})$  then there exists  $\mathbb{Q}$  such that  $(N, \mathsf{m}) = \mathcal{N}(\mathbb{Q})$  and  $\mathbb{P} \xrightarrow{\mu} \mathbb{Q}$  and  $\mu \equiv \mathsf{L}$ .

**Proof.** (1) It follows by induction on the structure of the derivation  $\mathbb{P} \xrightarrow{\mu} \mathbb{Q}$ . We show a few interesting cases.

(CASE STR<sub>s</sub>) P = (a, s; b).S, and P' = (a[k], s; b).S, and  $\mu = a[k]$  and  $a \in S$ , and std(S) and fresh(k, s). Then,  $(N, m) = (\mathcal{N}(a, s; b), \mathcal{M}(a, s; b))$ . By definition of the encoding there exists j such that  $\langle a, j \rangle \in T_{STR_s}((a, s; b))$  and  $\ell \langle a, j \rangle = a$  and  $*\langle a, j \rangle \in m$ . Since S is standard,  $\min_{S}(N_S)^{\bullet} = \emptyset$ , hence  $\circ\langle a, j \rangle = \emptyset$ . Consequently,  $(N, m) \xrightarrow{a} (N, m \setminus \{*\langle a, j \rangle\} \cup \{\langle a, j \rangle^*, \langle a, j \rangle^\dagger\}) = (\mathcal{N}((a[k], s; b).S), \mathcal{M}((a[k], s; b).S).$ 

(CASE STR<sub>m</sub>) P = (c, a, s; b).S, and  $P' = (c, a[\dagger l], s; b)$ .S, and  $\mu = c[k]$ , and std(s) and fresh(k, t). Then,  $(N, m) = (\mathcal{N}((c, a, s; b)), \mathcal{M}((c, a, s; b)))$ . By definition of encoding  $\langle c, a, i \rangle \in T_{STR_m}(c, a, s; b)$  and  $\ell \langle c, a, i \rangle = c$  and  $\langle a, i \rangle \in m$ . Moreover,  $m(\langle (c, 1)^* \rangle) = 0$  (because *c* appears without key in the prefix). Hence,  $\langle c, a, i \rangle$  is enabled. Then,  $(N, m) \xrightarrow{a} (N, (m \setminus \{ \langle a, i \rangle \}) \cup \{ \langle a, i \rangle \}) = (\mathcal{N}((c, a[\dagger l], s; b).S), \mathcal{M}((c, a[\dagger l], s; b).S))$  (note that the transition does not produce a token in the place  $\langle a, i \rangle^{\dagger}$ , hence the key associated with  $\langle a, i \rangle$ ) is invalidated).

(CASE WK)  $\mathbb{P} = (t; b).\mathbb{S}$ , and  $\mathbb{P}' = (t; b[k]).\mathbb{S}$ , and  $\mu = (b)[k]$  and  $std(\mathbb{S})$ , and fresh(k, t). By definition of encoding  $\langle b, 0 \rangle \in T_{WK}(t; b)$  and  $\ell \langle b, 0 \rangle = b$  and  $* \langle b, 0 \rangle \in m$ . Moreover, for all  $a \in \mathcal{A}$  and  $1 \le j \le t(a)$  we have  $* \langle a, i \rangle \notin m$  (because  $t \in \mathbb{N}^{\mathcal{A} \times \mathcal{K}}$ ). Hence,  $\langle b, 0 \rangle$  is enabled and the proof is completed as in the previous case.

(CASE COM)  $P = P \parallel Q$ ,  $P' = P' \parallel Q'$ ,  $\mu = \gamma(a, c)[k]$  and  $P \xrightarrow{a[k]} P'$  and  $Q \xrightarrow{c[k]} Q'$ . By inductive hypothesis,  $\mathcal{N}(P) \xrightarrow{a} \mathcal{N}(P')$  and  $\mathcal{N}(Q) \xrightarrow{c} \mathcal{N}(Q')$ . Hence, there are two transitions  $t_1$  and  $t_2$  s.t.  $\bullet t_1 \subseteq \mathcal{M}(P)$  and  $\ell(t_1) = a$  and  $\bullet t_2 \subseteq \mathcal{M}(Q)$  and  $\ell(t_2) = c$ . Hence,  $t_1 \parallel t_2 \in T_{P \parallel Q}$ . By inspecting the rules that have label in  $\mathcal{A}$  that are in the domain on  $\gamma$ , we conclude that they are transitions of the shape of  $T_{STR_s}$ ,  $T_{STR_w}$ , ore  $T_{STR_m}(a, c; b)$ . Since the presets in all cases are of the form  $*\langle a, i \rangle$ , it holds that  $\bullet t_i \subseteq \mathcal{M}(P \parallel Q)$  implies  $\bullet(t_1 \parallel t_2) \subseteq \mathcal{M}(P \parallel Q)$ . By definition of the encoding, it is also the case that  $\circ t_1 \cap \mathcal{M}(P) = \emptyset$  and  $\circ t_2 \cap \mathcal{M}(Q) = \emptyset$ , which imply  $\circ t_1 \parallel t_2 \cap \mathcal{M}(P \parallel Q) = \emptyset$ . Hence  $t_1 \parallel t_2$  is enabled at  $\mathcal{M}(P \parallel Q)$ . Consequently,  $\mathcal{N}(P \parallel Q) \xrightarrow{\gamma(a,c)} \mathcal{N}(P' \parallel Q')$ .

(CASE <u>COM</u>)  $\mathbb{P} = \mathbb{P} \parallel \mathbb{Q}, \mathbb{P}' = \mathbb{P}' \parallel \mathbb{Q}', \mu = \underline{\gamma}(a, c)[k] \text{ and } \mathbb{P} \xrightarrow{\underline{a}[k]} \mathbb{P}' \text{ and } \mathbb{Q} \xrightarrow{\underline{c}[k]} \mathbb{Q}'.$  By inductive hypothesis,  $\mathcal{N}(\mathbb{P}) \xrightarrow{\underline{a}} \mathcal{N}(\mathbb{P}')$  and

 $\begin{array}{ll} \mathcal{N}(\mathbb{Q}) \xrightarrow{\mathbb{C}} \mathcal{N}(\mathbb{Q}'). \ \text{Hence, there are two transitions } t_1 \ \text{and } t_2 \ \text{s.t.} \ {}^{\bullet}t_1 \subseteq \mathcal{M}(\mathbb{P}) \ \text{and } \ell(t_1) = \underline{a} \ \text{and} \ {}^{\bullet}t_2 \subseteq \mathcal{M}(\mathbb{Q}) \ \text{and} \ \ell(t_2) = \underline{c}. \\ \begin{array}{ll} \text{By inspecting the rules that have label in } \underline{A} \ \text{s.t. the forward transition is the domain on } \gamma, \ \text{we conclude that they are} \\ \begin{array}{ll} \text{transitions of the shape of } T_{\underline{STR}} \cup T_{\underline{STR}_p} \cup T_{\underline{STR}_m}. \ \text{We analyse the case in which } t_1 \ \text{comes from which } T_{\underline{STR}_m} \ \text{(the other follows} \\ \end{array} \\ \begin{array}{ll} \text{by analogous arguments}. \ \text{Hence, } t_1 = \langle \underline{a}, i, d \rangle, \ {}^{\bullet}\langle \underline{a}, i, d \rangle = \{\langle \underline{a}, i \rangle^{\dagger}, \langle d, 1 \rangle^{\dagger}\}, \ \langle \underline{a}, i, d \rangle^{\bullet} = \{{}^{*}\langle d, 1 \rangle\}, \ {}^{\circ}\langle \underline{a}, i, d \rangle = \{\langle b, 0 \rangle^{*}\}. \\ \end{array} \\ \begin{array}{ll} \text{First note that } \langle \underline{a}, i \rangle^{\dagger} \notin \mathcal{M}(\mathbb{P}\|\mathbb{Q}) \ \text{(because the key between a and c is bound). By definition of the encoding, there should \\ \end{array} \\ \begin{array}{ll} \text{some synchronisation } \alpha \in \mathcal{N}(\mathbb{P}\|\mathbb{Q}) \ \text{such that } \alpha\langle \underline{a}, i \rangle^{\dagger} \in \mathcal{M}(\mathbb{P}\|\mathbb{Q}). \ \text{In case } \langle d, 1 \rangle^{\dagger} \in \mathcal{M}(\mathbb{P}\|\mathbb{Q}), \ \text{we can conclude that bt} t_1, a, \alpha) \\ \end{array} \\ \begin{array}{ll} \text{is enabled at } \mathcal{M}(\mathbb{P}\|\mathbb{Q}). \ \text{If } \langle d, 1 \rangle^{\dagger} \notin \mathcal{M}(\mathbb{P}\|\mathbb{Q}), \ \text{then, there exists a synchronisation } \beta \ \text{such that bt} (bt(t, a, \alpha), c, \beta) \ \text{is enabled at} \\ \mathcal{M}(\mathbb{P}\|\mathbb{Q}). \ \text{Consequently, there is a transition } \langle t_1' \oplus t_2' \rangle \ \text{(coming from } T_A) \ \text{that is enabled at } \mathcal{M}(\mathbb{P}\|\mathbb{Q}). \ \text{Hence, we can conclude that} \\ \end{array} \\ \begin{array}{l} \text{that } \mathcal{N}(\mathbb{P}\|\mathbb{Q}) \ \frac{\gamma(a,c)}{1} \longrightarrow \mathcal{N}(\mathbb{P}'\|\mathbb{Q}'). \end{array} \end{array}$ 

(2) follows by induction on the structure of P. Let t be the fired transition and note that  $\ell(t) = L$ . Hence,

$$(\mathcal{N}(\mathbb{P}), \mathcal{M}(\mathbb{P})) \xrightarrow{\mathsf{L}} (\mathcal{N}(\mathbb{P}), \mathcal{M}(\mathbb{P}) \setminus {}^{\bullet}t \cup t^{\bullet})$$

(CASE  $P = \alpha$ .S). Then,  $\mathcal{N}(P) = \mathcal{N}(\alpha.S)$  and  $\mathcal{M}(P) = \mathcal{M}(\alpha.S) = \mathcal{M}(\alpha) \uplus \mathcal{M}(S)$ . By Definition 24, there are two cases:

•  $t \in T_{\alpha}$ :  $(\mathcal{N}(\alpha.S), \mathcal{M}(\alpha.S)) \xrightarrow{\mathsf{L}} (\mathcal{N}(\alpha.S), \mathcal{M}(\alpha) \setminus t \cup t^{\bullet} \uplus \mathcal{M}(S)).$ 

We first note that  $\min_{\mathcal{S}}(\mathcal{N}(S))^{\bullet} \cap \mathcal{M}(\alpha, S) = \emptyset$ , otherwise *t* would not be enabled because of the inhibitor arcs in Bw from Definition 24. Therefore S is standard. We proceed by case analysis on the shape of *t*. We illustrate the case

JID:TCS AID:13224 /FLA Doctopic: Theory of natural computing H. Melgratti, C.A. Mezzina and G.M. Pinna [m3G; v1.312] P.29 (1-31) Theoretical Computer Science ••• (••••) •••-•••

in which  $t \in T_{STR_s}(\alpha)$  (the remaining cases follow analogously). There must exist a, *s*, *b* and *j* such that  $\alpha = (a, s; b)$ ,  $\langle a, j \rangle \in T_{STR_s}(\alpha)$  and  $\ell \langle a, j \rangle = a = L$  and  $* \langle a, j \rangle \in \mathcal{M}(\alpha)$ . Consequently,

$$(\mathcal{N}(\alpha.\mathrm{S}), \mathcal{M}(\alpha) \uplus \mathcal{M}(\mathrm{S})) \xrightarrow{a} (\mathcal{N}(\alpha.\mathrm{S}), \mathcal{M}(\alpha) \setminus \{^* \langle a, j \rangle\} \cup \{ \langle a, j \rangle^*, \langle a, j \rangle^{\dagger} \} \uplus \mathcal{M}(\mathrm{S}))$$

Since *S* is standard, we have that  $\alpha.S = (a, s; b).S \xrightarrow{a[k]} (a[k], s; b).S$  by rule  $(sTR_s)$ . The proof is completed by taking Q = (a[k], s; b).S and  $\mu = a[k]$  and noting that  $\mathcal{M}(Q) = \mathcal{M}(\alpha) \setminus \{^*\langle a, j \rangle\} \cup \{\langle a, j \rangle^*, \langle a, j \rangle^{\dagger}\} \oplus \mathcal{M}(S)$ .

•  $t \in T_S$ . We have  $\mathcal{M}(\alpha.S) \cap \{ \{ \langle a, i \rangle \in S_{(s;b)} \} \cup \{ \langle b, 0 \rangle^* \} \} = \emptyset$ , as otherwise *t* would not be enabled because of the inhibitor arcs in Fw. Hence,  $\alpha = (t; b)$ . The proof is completed by applying inductive hypothesis and (cont).

(CASE  $P = P_1 | P_2$ ). If  $t \in T_{P_i}$  then the proof follows by inductive hypothesis and rule PAR. If  $t \in T_{(P_1 || P_2)}$ , then there exist  $t_1 \in T_{P_1}$  and  $t_2 \in T_{P_2}$  and  $\gamma(t_1, t_2) \downarrow$ . The proof is completed by applying inductive hypothesis on both  $t_1$  and  $t_2$  and rule COM. If  $t \in T_{(P_1 || P_2)} \cup T_{\kappa(P_1 || P_2)}$ , then the proof follows by applying inductive hypothesis and rule (<u>COM</u>).

(CASE  $P = S \setminus L$ ) It follows by inductive hypothesis and rule (RES).  $\Box$ 

To recover the original CCB one has simply to restrict the actions/transitions to those with the allowed labels.

### 7. Conclusions

We have investigated how a calculus for covalent bonding can be rendered into Petri nets in a compositional and conservative way. We started from the *Calculus of Covalent Bonding* (CCB) [31,8]. In this calculus created bonds (interactions between actions) can be broken (aka reversed) concerting them with other actions or bonds. Indeed, the *concerting* capability is the distinguishing feature of the calculus. We have first faced some critical issues the act of concerting has. One difficulty stems from the fact that a concerted action involves the formation of a weak bond along with the undoing of a strong one. Another one concerns weak bonds that can be promoted (e.g., passed) to strong ones. To overcome these criticalities we have remodelled the CCB semantics to make it compositional, remaining consistent with the original semantics as it is described in [8], and we have therefore proposed rules mimicking, in a compositional fashion, the concert rules and the pre-congruence ones. We stress that, being our proposal on CCB a conservative one, all the interesting biochemical reactions which are described as CCB processes can be described using our set of rules.

We have then introduced a class of Petri nets, called *covalent* bond nets (CBNS), where dependencies among actions are modelled via inhibitor arcs, similarly to what is done in [17]. Following [18] we have then presented a compositional encoding of the (compositional) CCB to bond nets. Needless to say the main difficulties arise when composing in parallel two bond nets derived from two CCB processes. This is due to the fact that one has to account for all the possible synchronisations, concerted actions and promotions of bonds. Concerted actions are the most difficult ones to rend on a net, as they have to mimic several derivations of the calculus in just one firing. One peculiarity of our encoding is that keys are rendered as extra places, marking the fact that a certain action have been done. We stress that in our net encoding all the auxiliary predicates like *fresh* or *std* are hardwired. Keys are represented, in the net encoding, as key places, which implies that it is unnecessary to check whether the key is available or not. Well-stratifiedness engineers the predicate *std*.

Our main results are stated by Theorem 1 and Theorem 2. Theorem 1 serves as sanity check of our encoding, and tells us that a net derived from the encoding of a CCB terms is indeed a CBN. Theorem 2 states an operational correspondence between CCB term and its net counterpart.

The net encoding of a CCB term have advantages stemming from the Petri Nets world, for instance analysis techniques arising from the Petri Nets world can be fruitfully used, or the usage of behavioural equivalences originated in the Petri Nets theory. It has a drawback that all these encodings have, namely that the need of representing all the possible interactions using transitions makes the net rather big. We however stress that this is also a problem when considering the computations of a CCB term.

Several possible lines of future work can be envisaged. The first one could be to see what whether CBNS can be rendered into reversible Prime Event structures [42] following the construction of [17]. Also we could resort to colours in our bond nets to avoid some extra machinery in the parallel composition. This would allow us to integrate it with the CPN tool [43], and to have an integrated tool for modelling bonds.
