Separating invariants
Modular cyclic groups

#### Abstract

We consider a finite-dimensional indecomposable modular representation of a cyclic $p$-group and we give a recursive description of an associated separating set: We show that a separating set for a representation can be obtained by adding, to a separating set for any subrepresentation, some explicitly defined invariant polynomials. Meanwhile, an explicit generating set for the invariant ring is known only in a handful of cases for these representations.

## 1. Introduction

Let $V$ denote a finite-dimensional representation of a group $G$ over a field $F$. The induced action on the dual space $V^{*}$ extends to the symmetric algebra $S\left(V^{*}\right)$. This is a polynomial algebra in a basis of $V^{*}$ and we denote it by $F[V]$. The action of $\sigma \in G$ on $f \in F[V]$ is given by $(\sigma f)(v)=f\left(\sigma^{-1} v\right)$ for $v \in V$. The subalgebra in $F[V]$ of polynomials that are left fixed under the action of the group is denoted by $F[V]^{G}$. A classical problem is to determine the invariant ring $F[V]^{G}$ for a given representation. This is, in general a difficult problem because the invariant ring becomes messier if one moves away from the groups generated by reflections and the degrees of the generators often get very big. A subset $A \subseteq F[V]^{G}$ is said to be separating for $V$ if for any pair of vectors $u, w \in V$, we have: If $f(u)=f(w)$ for all $f \in A$, then $f(u)=f(w)$ for all $f \in F[V]^{G}$. Separating invariants have been a recent trend in invariant theory as a better behaved weakening of generating invariants. Although distinguishing between the orbits with invariants has been an object of study since the beginning of invariant theory, there has been a recent resurgence of interest in them which is initiated by Derksen and Kemper [6]. Since then, there have been several papers with the theme that one can get separating subalgebras with better constructive properties which make them easier to obtain than the full invariant ring. For instance there is always a finite separating set [6, 2.3.15.] and Noether's bound holds for separating invariants independently of the characteristic of the field [6, 3.9.14.]. Separating

[^0]invariants also satisfy important efficiency properties in decomposable representations, [8,9] and [10], see also [14]. Obtaining a generating set for the invariant ring is particularly difficult in the modular case, i.e., when the order of the group is divisible by the characteristic of the field. Even in the simplest situation of a representation of a cyclic group of prime order $p$ over a field of characteristic $p$, an explicit generating set is known only in very limited cases. On the other hand both Derksen-Kemper [6, 3.9.14.] and Dufresne [11] give an explicit construction of a separating set for any finite group action. Moreover, a separating set that consists of relatively small number of invariants of a special form is constructed for every modular representation of a cyclic group of prime order in [25]. We will tell more about modular representations shortly.

There has been also some interest in the question whether one can improve the ring theoretical properties by passing to a separating subalgebra. In [12] it is shown that there may exist a regular (resp. complete intersection) separating subalgebra where the invariant ring is not regular (resp. complete intersection). But some recent results [13] and [16] suggest that, in general, separating subalgebras do not provide substantial improvements in terms of the Cohen-Macaulay defect.

We recommend [6, 2.3.2, 3.9.4] and [19] for more background and motivation on separating invariants. The textbooks [1,6] and [23] are good sources as general references in invariant theory.

In this paper we study separating invariants for indecomposable representations of a cyclic $p$ group $\boldsymbol{Z}_{p^{r}}$ over a field of characteristic $p$, where $r$ is a positive integer. Although these representations are easy to describe the corresponding invariant ring is difficult to obtain. A major difficulty is that, as shown by Richman [24], the degrees of the generators increase unboundedly as the dimension of the representation increases. Actually for $r=1$, the maximal degree of a polynomial in a minimal generating set for the invariant ring of any representation is known, see [18]. Nevertheless, explicit generating sets are available only for handful of cases. The invariants of the two and the three-dimensional indecomposable representations of $\boldsymbol{Z}_{p}$ were computed by Dickson [7] at the beginning of the twentieth century. After a long period without progress Shank [26] obtained the invariants of the four and the five-dimensional indecomposable representations using difficult computations that involved SAGBI bases. In a recent preprint [30], Wehlau proved a conjecture of Shank that reduces the computation of generators for $F[V]^{Z_{p}}$ to the classical problem of computing the $S L_{2}(\mathbf{C})$ invariants of a particular representation that is easily obtained from $V$. This connection leads to generators for the invariants of indecomposable representations of $\boldsymbol{Z}_{p}$ up to dimension nine, see [30,10.8]. As for decomposable representations, the invariants for copies of the two-dimensional indecomposable representation were computed by Campbell and Hughes [3], see also [5]. The adoption of SAGBI bases method that was introduced by Shank together with the recent work of Wehlau that builds on the connection with the $S L_{2}(\boldsymbol{C})$ invariants also helped to resolve the cases where each indecomposable summand has dimension at most four, see [2,15,27] and [30]. For $r=2$ much less is known: Shank and Wehlau gave a generating set for the invariants of the $(p+1)$-dimensional indecomposable representation [28]. Also in [21], a bound for the degrees of generators that applies to all indecomposable representations of $Z_{p^{2}}$ was obtained. As a polynomial in $p$, this bound is of degree two and together with the bounds for $Z_{p}$ it gives support for a general conjecture on the degrees of the generators of modular invariants of $\boldsymbol{Z}_{p^{r}}$, see [21]. Meanwhile, for $r>2$, to the best of our information, no explicit description of a generating set exists for the invariants of any faithful representation. We note that Symonds [29] recently established that the invariant ring $F[V]^{G}$ is generated in degrees at most $(\operatorname{dim} V)(|G|-1)$ for any representation $V$ of any group $G$, but the bound we mention above for the cyclic $p$-groups are much more efficient than Symonds' bound. Some other recent results on degree bounds for separating invariants can be found in a paper by Kohls [20].

Despite these complications concerning the modular generating invariants, separating invariants have been revealed to be remarkably better behaved. In [22] a separating set is constructed using only transfers and norms for any modular representation of any $p$-group. These are invariant polynomials that are obtained by taking orbit sums and orbit products. They are easy to obtain and it is known that they do not suffice to generate the invariant ring even when the group is cyclic. Unfortunately the size of the set in [22] is infinite. In [25] the focus is restricted to representations of $\boldsymbol{Z}_{p}$ and more explicit results are obtained. More precisely, it is shown that a separating set for a representation can be obtained by adding, to a separating set of a certain subrepresentation, some explicitly described invariant polynomials. This result is special to separating invariants and expresses their distinction from
generating invariants in several directions. First of all, knowing the invariants of subrepresentations is not critically useful in building up a generating set for higher-dimensional representations. Practically, it is equally difficult to get a generating set for the invariants of a representation even when one is supplied with the invariants of its subrepresentations. Also the construction in [25] yields a separating set for any representation that consists of polynomials of degree one or $p$ and the size of this set depends only on the dimension of the representation. On the other hand, the size of a generating set depends also on the order of the group and the degrees of the generators are somewhat randomly distributed. Moreover, each polynomial in this separating set depends on variables from at most two indecomposable summands in the representation, whereas a minimal generating set must contain a polynomial that involves a variable from every non-trivial indecomposable summand, see [18].

The purpose of this paper is to generalize the construction in [25] to all modular indecomposable representations of an arbitrary cyclic $p$-group $\boldsymbol{Z}_{p^{r}}$. Since the dual of a subrepresentation still sits in the duals of higher-dimensional representations for cyclic $p$-groups (we will be more precise about this in the next section), the strategy of building on separating sets for subrepresentations carries over to this generality. As in [25], this allows us to reduce to the problem of separating two vectors whose coordinates are all the same except the coordinate corresponding to the fixed point space. In the lower triangular basis this is the last coordinate. Then we split the pairs according to the lengths of the tails of zeros in their coordinates. It turns out that, for an integer $j \geqslant 1$, all pairs of vectors (in different orbits) whose $j$ th coordinates are non-zero and the lower coordinates are zero can be separated by the same polynomial. While this polynomial is simply a transfer of a single monomial of degree $p$ in the $Z_{p}$ case for $j<\operatorname{dim} V-1$, we take a large relative transfer of a certain product of norms with respect to the right subgroup in the general treatment. The choice of the subgroup depends on the base $p$ expansion of $\operatorname{dim} V-j$. Since we are using this polynomial to separate vectors whose tails of zeros have the same length, we compute this polynomial modulo the vanishing ideal of the vector space corresponding to the common tail. This is the most difficult part of the proof. If all coordinates except the last two are all zero in a given pair, then the norm of the linear form corresponding to the last coordinate separates this pair. Hence we obtain a set of invariants that connect separating sets of two indecomposable representations of consecutive dimensions. By induction this yields an explicit (finite) separating set for all indecomposable representations. This set has nice constructive features as in the case of $\boldsymbol{Z}_{p}$. From the construction it can be read off that the size of the separating set depends only on the dimension of the representation. Moreover, the maximal degree of a polynomial in this set is the group order $p^{r}$ and there are $p^{r-1}+1$ possibilities for the degree of a polynomial in this set.

## 2. Constructing separating invariants

Let $p>0$ be a prime number and $F$ be a field of characteristic $p$. Let $G$ denote the cyclic group of order $p^{r}$, where $r$ is a positive integer. Representation theory of $G$ over $F$ is not difficult and we direct the reader to the introduction in [28] for a general reference. Fix a generator $\sigma$ of $G$. There are exactly $p^{r}$ indecomposable representations $V_{1}, V_{2}, \ldots, V_{p^{r}}$ of $G$ up to isomorphism where $\sigma$ acts on $V_{n}$ for $1 \leqslant n \leqslant p^{r}$ by a Jordan block of dimension $n$ with ones on the diagonal. Let $e_{1}, e_{2}, \ldots, e_{n}$ be the Jordan block basis for $V_{n}$ with $\sigma\left(e_{i}\right)=e_{i}+e_{i+1}$ for $1 \leqslant i \leqslant n-1$ and $\sigma\left(e_{n}\right)=e_{n}$. We identify each $e_{i}$ with the column vector with 1 on the $i$ th coordinate and zero elsewhere. Let $x_{1}, x_{2}, \ldots, x_{n}$ denote the corresponding elements in the dual space $V_{n}^{*}$. Since $V_{n}^{*}$ is indecomposable it is isomorphic to $V_{n}$. In fact, $x_{1}, x_{2}, \ldots, x_{n}$ forms a Jordan block basis for $V_{n}^{*}$ in the reverse order: We have $\sigma^{-1}\left(x_{i}\right)=x_{i}+x_{i-1}$ for $2 \leqslant i \leqslant n$ and $\sigma^{-1}\left(x_{1}\right)=x_{1}$. For simplicity we will use the generator $\sigma^{-1}$ instead of $\sigma$ for the rest of the paper and change the notation by writing $\sigma$ for the new generator. Note also that $F\left[V_{n}\right]=F\left[x_{1}, x_{2}, \ldots, x_{n}\right]$. Pick a column vector $\left(c_{1}, c_{2}, \ldots, c_{n}\right)^{t}$ in $V_{n}$, where $c_{i} \in F$ for $1 \leqslant i \leqslant n$. There is a $G$-equivariant surjection $V_{n} \rightarrow V_{n-1}$ given by $\left(c_{1}, c_{2}, \ldots, c_{n}\right)^{t} \rightarrow\left(c_{1}, c_{2}, \ldots, c_{n-1}\right)^{t}$. We use the convention that $V_{0}$ is the zero representation. Dual to this surjection, the subspace in $V_{n}^{*}$ generated by $x_{1}, x_{2}, \ldots, x_{n-1}$ is closed under the $G$-action and is isomorphic to $V_{n-1}^{*}$. Hence $F\left[V_{n-1}\right]=F\left[x_{1}, x_{2}, \ldots, x_{n-1}\right]$ is a subalgebra in $F\left[V_{n}\right]$. For $0 \leqslant m \leqslant r$, let $G_{m}$ denote the subgroup of $G$ of order $p^{m}$ which is generated by $\sigma^{p^{r-m}}$. For $f \in F\left[V_{n}\right]$, define $N_{G_{m}}(f)=\prod_{0 \leqslant 1 \leqslant p^{m}-1} \sigma^{l p^{r-m}}(f)$ and for simplicity we write $N_{G}(f)$ for $N_{G_{r}}(f)$. Also for $f \in F\left[V_{n}\right]^{G_{m}}$, define the relative transfer
$\operatorname{Tr}_{G_{m}}^{G}(f)=\sum_{0 \leqslant 1 \leqslant p^{r-m}-1} \sigma^{l}(f)$. Notice that $N_{G_{m}}(f) \in F\left[V_{n}\right]^{G_{m}}$ and $\operatorname{Tr}_{G_{m}}^{G}(f) \in F\left[V_{n}\right]^{G}$. For a positive integer $i$. Let $I_{i}$ denote the ideal in $F\left[V_{n}\right]$ generated by $x_{1}, x_{2}, \ldots, x_{i}$ if $1 \leqslant i \leqslant n$ and let $I_{i}$ denote the zero ideal if $i>n$. Since the vector space generated by $x_{1}, x_{2}, \ldots, x_{i}$ is closed under the $G$-action, $I_{i}$ is also closed under the $G$-action.

Let $1 \leqslant j \leqslant n-2$ be an integer with $p^{k-1}+1 \leqslant n-j \leqslant p^{k}$, where $k$ is a positive integer. We define the polynomial

$$
H_{j, n}=\operatorname{Tr}_{G_{r-k}}^{G}\left(\left(N_{G_{r-k}}\left(x_{n}\right)\right) \prod_{0 \leqslant i \leqslant k-1}\left(N_{G_{r-k}}\left(x_{j+p^{i}}\right)\right)^{p-1}\right) .
$$

It turns out that this polynomial is the right generalization of the polynomial in [25, Lemma 2] for our purposes. Our main task before the proof of the main theorem is to compute this polynomial modulo the ideal $I_{j-1}$. We start with a couple of well known results.

## Lemma 1.

1) Let a be a positive integer. Then $\sum_{0 \leqslant 1 \leqslant p-1} l^{a} \equiv-1 \bmod p$ if $p-1$ divides a and $\sum_{0 \leqslant l \leqslant p-1} l^{a} \equiv 0 \bmod p$, otherwise.
2) Let $s, t$ be integers with base $p$ expansions $t=a_{m} p^{m}+a_{m-1} p^{m-1}+\cdots+a_{0}$ and $s=b_{m} p^{m}+$ $b_{m-1} p^{m-1}+\cdots+b_{0}$, where $0 \leqslant a_{i}, b_{i} \leqslant p-1$ for $1 \leqslant i \leqslant m$. Then $\binom{t}{s} \equiv \prod_{0 \leqslant i \leqslant m}\binom{a_{i}}{b_{i}} \bmod p$.

Proof. We direct the reader to [4, 9.4] for a proof of the first statement and to [17] for a proof of the second statement.

From now on all equivalences are modulo $I_{j-1}$ unless otherwise stated.

Lemma 2. We have the following equivalences.

1) $N_{G_{r-k}}\left(x_{j+p^{i}}\right) \equiv x_{j+p^{i}}^{p^{r-k}}$ for $0 \leqslant i \leqslant k-1$.
2) $N_{G_{r-k}}\left(x_{n}\right) \equiv \begin{cases}x_{n}^{p^{r-k}} & \text { if } n-j \neq p^{k}, \\ x_{n}^{p^{r-k}}-x_{n}^{r^{r-k-1}} x_{n-p^{k}}^{(p-1) r-k-1} & \text { if } n-j=p^{k} .\end{cases}$

Proof. Let $1 \leqslant m \leqslant n$ be an integer. We first claim that $N_{G_{r-k}}\left(x_{m}\right) \equiv x_{m}^{r^{r-k}} \bmod I_{m-p^{k}}$. Since $\sigma^{p^{k}}\left(x_{m}\right)=$ $x_{m}+p^{k} x_{m-1}+\binom{p^{k}}{2} x_{m-2}+\cdots$, by the previous lemma we have $\sigma^{p^{k}}\left(x_{m}\right)=x_{m}+x_{m-p^{k}}$. Therefore for $0 \leqslant l \leqslant p^{r-k}-1$, we get $\sigma^{l p^{k}}\left(x_{m}\right)=x_{m}+l x_{m-p^{k}}+\binom{l}{2} x_{m-2 p^{k}}+\cdots \equiv x_{m} \bmod I_{m-p^{k}}$. Since $N_{G_{r-k}}\left(x_{m}\right)=$ $\prod_{0 \leqslant l \leqslant p^{r-k}-1} \sigma^{l p^{k}}\left(x_{m}\right)$, we obtain the claim.

From the claim we have $N_{G_{r-k}}\left(x_{j+p^{i}}\right) \equiv x_{j+p^{i}}^{p^{r-k}} \bmod I_{j+p^{i}-p^{k}}$. But since $I_{j+p^{i}-p^{k}}$ is contained in $I_{j-1}$, the first statement of the lemma follows. Similarly, if $n-j \neq p^{k}$, then $N_{G_{r-k}}\left(x_{n}\right) \equiv x_{n}^{p^{r-k}}$ because $I_{n-p^{k}}$ is contained in $I_{j-1}$. On the other hand, if $n-j=p^{k}$, then $\sigma^{l p^{k}}\left(x_{n}\right)=x_{n}+l x_{n-p^{k}}+\binom{l}{2} x_{n-2 p^{k}}+\cdots \equiv$ $x_{n}+l x_{n-p^{k}}$ and therefore $N_{G_{r-k}}\left(x_{n}\right) \equiv \prod_{0 \leqslant 1 \leqslant p^{r-k}-1}\left(x_{n}-l x_{n-p^{k}}\right)$. Furthermore, $\prod_{0 \leqslant 1 \leqslant p^{r-k}-1}\left(x_{n}-\right.$ $\left.l x_{n-p^{k}}\right) \equiv\left(\prod_{0 \leqslant l \leqslant p-1}\left(x_{n}+l x_{n-p^{k}}\right)\right)^{p^{r-k-1}}$. But it is well known that $\prod_{0 \leqslant l \leqslant p-1}\left(x_{n}+l x_{n-p^{k}}\right)=x_{n}^{p}-$ $x_{n} x_{n-p^{k}}^{p-1}$, see for instance [7, §3]. It follows that $N_{G_{r-k}}\left(x_{n}\right) \equiv x_{n}^{p^{r-k}}-x_{n}^{p^{r-k-1}} x_{n-p^{k}}^{(p-1) p^{r-k-1}}$.

For simplicity we put $X=\left(\prod_{0 \leqslant i \leqslant k-1}\left(N_{G_{r-k}}\left(x_{j+p^{i}}\right)\right)^{p-1}\right)$.

Lemma 3. There exists $f \in F\left[x_{1}, x_{2}, \ldots, x_{n-1}\right]$ such that

$$
H_{j, n} \equiv N_{G_{r-k}}\left(x_{n}\right) \operatorname{Tr}_{G_{r-k}}^{G}(X)+f .
$$

Proof. We claim that for $0 \leqslant l \leqslant p^{k}-1$ there exists $g_{l} \in F\left[x_{1}, x_{2}, \ldots, x_{n-1}\right]$ such that $\sigma^{l}\left(N_{G_{r-k}}\left(x_{n}\right)\right) \equiv$ $N_{G_{r-k}}\left(x_{n}\right)+g_{l}$. First assume that $n-j \neq p^{k}$. Then by the previous lemma we have $N_{G_{r-k}}\left(x_{n}\right) \equiv x_{n}^{r^{r-k}}$. Since this equivalence is preserved under the action of the group we get

$$
\begin{aligned}
\sigma^{l}\left(N_{G_{r-k}}\left(x_{n}\right)\right) & \equiv x_{n}^{p^{r-k}}+\left(l x_{n-1}\right)^{p^{r-k}}+\left(\binom{l}{2} x_{n-2}\right)^{p^{r-k}}+\cdots \\
& =x_{n}^{p^{r-k}}+l x_{n-1}^{p^{r-k}}+\binom{l}{2} x_{n-2}^{p^{r-k}}+\cdots .
\end{aligned}
$$

Hence we can choose $g_{l}=l x_{n-1}^{p^{r-k}}+\binom{l}{2} x_{n-2}^{p^{r-k}}+\cdots$. Next assume that $n-j=p^{k}$. By the previous lemma again, we have $N_{G_{r-k}}\left(x_{n}\right) \equiv x_{n}^{p^{r-k}}-x_{n}^{p^{r-k-1}} x_{n-p^{k}}^{(p-1) p^{r-k-1}}$. Similarly we get

$$
\sigma^{l}\left(N_{G_{r-k}}\left(x_{n}\right)\right) \equiv\left(x_{n}^{p^{r-k}}+l x_{n-1}^{r^{r-k}}+\cdots\right)-\left(x_{n}^{r^{r-k-1}}+l x_{n-1}^{p^{r-k-1}}+\cdots\right) x_{n-p^{k}}^{(p-1) p^{r-k-1}}
$$

where we used $\sigma^{l}\left(x_{n-p^{k}}^{(p-1) p^{r-k-1}}\right) \equiv x_{n-p^{k}}^{(p-1) p^{r-k-1}}$. Therefore we can choose $g_{l}=\left(l x_{n-1}^{p^{r-k}}+\binom{l}{2} x_{n-2}^{p^{r-k}}+\cdots\right)-$ $\left(l x_{n-1}^{p^{r-k-1}}+\binom{l}{2}_{n-2}^{p^{r-k-1}}+\cdots\right)\left(x_{n-p^{k}}^{(p-1) p^{r-k-1}}\right)$. This establishes the claim. It follows that

$$
\begin{aligned}
H_{j, n} & =\sum_{0 \leqslant l \leqslant p^{k}-1} \sigma^{l}\left(N_{G_{r-k}}\left(x_{n}\right) X\right)=\sum_{0 \leqslant l \leqslant p^{k}-1} \sigma^{l}\left(N_{G_{r-k}}\left(x_{n}\right)\right) \sigma^{l}(X) \\
& \equiv \sum_{0 \leqslant 1 \leqslant p^{k}-1}\left(N_{G_{r-k}}\left(x_{n}\right)\right) \sigma^{l}(X)+\sum_{0 \leqslant l \leqslant p^{k}-1} g_{l} \sigma^{l}(X) \\
& =N_{G_{r-k}}\left(x_{n}\right) \operatorname{Tr}_{G_{r-k}}^{G}(X)+\sum_{0 \leqslant 1 \leqslant p^{k}-1} g_{l} \sigma^{l}(X) .
\end{aligned}
$$

Notice that the smallest index of a variable in $X$ is $j+p^{k-1}$ which is strictly smaller than $n$. So $X$ lies in $F\left[x_{1}, x_{2}, \ldots, x_{n-1}\right]$ as well. Hence the result follows.

We turn our attention to the polynomial $\operatorname{Tr}_{G_{r-k}}^{G}(X)$. By Lemma 2 we have

$$
\operatorname{Tr}_{G_{r-k}}^{G}(X) \equiv \sum_{0 \leqslant l \leqslant p^{k}-1} \sigma^{l}\left(\prod_{0 \leqslant i \leqslant k-1}\left(x_{j+p^{i}}\right)^{p^{r-k}(p-1)}\right)
$$

We set

$$
T=\sum_{0 \leqslant 1 \leqslant p^{k}-1} \sigma^{l}\left(\prod_{0 \leqslant i \leqslant k-1}\left(x_{j+p^{i}}\right)^{p^{r-k}(p-1)}\right) .
$$

For $0 \leqslant m \leqslant k(p-1)-1$, write $m=a_{m}(p-1)+b_{m}$, where $a_{m}, b_{m}$ are non-negative integers with $0 \leqslant b_{m}<p-1$. Define $w_{m, 0}=\left(x_{\left.j+p^{a m}\right)} p^{p^{r-k}}\right.$ and for an integer $t \geqslant 0$, set $w_{m, t}=\left(x_{j+p^{a m}-t}\right)^{p^{r-k}}$. Note that we have

$$
\prod_{0 \leqslant i \leqslant k-1}\left(x_{j+p^{i}}\right)^{p^{r-k}(p-1)}=\prod_{0 \leqslant m \leqslant k(p-1)-1} w_{m, 0}
$$

For a $k(p-1)$-tuple $\alpha=[\alpha(0), \alpha(1), \ldots, \alpha(k(p-1)-1)] \in \mathbb{N}^{k(p-1)}$, define

$$
w_{\alpha}=\prod_{0 \leqslant m \leqslant k(p-1)-1} w_{m, \alpha(m)}
$$

Next lemma shows that $T$ can be written as a linear combination of $w_{\alpha}$ 's.
Lemma 4. We have $T=\sum_{w_{\alpha} \in \mathbb{N}^{k(p-1)}} c_{\alpha} w_{\alpha}$, where

$$
c_{\alpha}=\sum_{0 \leqslant l \leqslant p^{k}-1}\left(\prod_{0 \leqslant m \leqslant k(p-1)-1}\binom{l}{\alpha(m)}\right)
$$

Proof. We have

$$
\begin{aligned}
T & =\sum_{0 \leqslant l \leqslant p^{k}-1} \sigma^{l}\left(\prod_{0 \leqslant i \leqslant k-1}\left(x_{j+p^{i}}\right)^{p^{r-k}(p-1)}\right) \\
& =\sum_{0 \leqslant l \leqslant p^{k}-1}\left(\prod_{0 \leqslant i \leqslant k-1}\left(\sigma^{l}\left(x_{j+p^{i}}\right)\right)^{p^{r-k}(p-1)}\right) \\
& =\sum_{0 \leqslant l \leqslant p^{k}-1}\left(\prod_{0 \leqslant i \leqslant k-1}\left(x_{j+p^{i}}+l x_{j+p^{i}-1}+\binom{l}{2} x_{j+p^{i}-2}+\cdots\right)^{p^{r-k}(p-1)}\right) \\
& =\sum_{0 \leqslant l \leqslant p^{k}-1}\left(\prod _ { 0 \leqslant i \leqslant k - 1 } \left(x_{j+p^{i}}^{\left.\left.p^{r-k}+l x_{j+p^{i}-1}^{p^{r-k}}+\binom{l}{2} x_{j+p^{i}-2}^{p^{r-k}}+\cdots\right)^{p-1}\right)}\right.\right. \\
& =\sum_{0 \leqslant l \leqslant p^{k}-1}\left(\prod_{0 \leqslant m \leqslant k(p-1)-1}\left(w_{m, 0}+l w_{m, 1}+\binom{l}{2} w_{m, 2}+\cdots\right)\right) .
\end{aligned}
$$

Hence we get the result.
Let $\alpha^{\prime}$ denote the $k(p-1)$-tuple such that $\alpha^{\prime}(m)=p^{a_{m}}$ for $0 \leqslant m \leqslant k(p-1)-1$. Notice that $w_{\alpha^{\prime}}=$ $x_{j}^{p^{r-k} k(p-1)}$. We show that $T$ is in fact equivalent to a scalar multiple of this monomial modulo $I_{j-1}$.

Lemma 5. We have $c_{\alpha^{\prime}} \neq 0$. Moreover, $T \equiv c_{\alpha^{\prime}} w_{\alpha^{\prime}}$.
Proof. Let $\alpha \in \mathbb{N}^{k(p-1)}$ with $w_{\alpha} \notin I_{j-1}$. We have $\alpha(m)-p^{a_{m}} \leqslant 0$ for all $0 \leqslant m \leqslant k(p-1)-1$, because otherwise $w_{m, \alpha(m)}=\left(x_{j+p^{a_{m}-\alpha(m)}}\right)^{r-k} \in I_{j-1}$. But since $m \leqslant k(p-1)-1$, we have $a_{m} \leqslant k-1$ and therefore $\alpha(m) \leqslant p^{k-1}$ for all $0 \leqslant m \leqslant k(p-1)-1$. In particular it follows that the base $p$ expansion of $\alpha(m)$ contains at most $k$ digits. For $0 \leqslant m \leqslant k(p-1)-1$ and $0 \leqslant l \leqslant p^{k}-1$, let $\alpha(m)=\alpha(m)_{k-1} p^{k-1}+$ $\alpha(m)_{k-2} p^{k-2}+\cdots+\alpha(m)_{0}$ and $l=l_{k-1} p^{k-1}+l_{k-2} p^{k-2}+\cdots+l_{0}$ denote the base $p$ expansions of $\alpha(m)$ and $l$, respectively. From Lemmas 1 and 4 we have

$$
\begin{aligned}
c_{\alpha} & =\sum_{0 \leqslant l \leqslant p^{k}-1}\left(\prod_{0 \leqslant m \leqslant k(p-1)-1}\binom{l}{\alpha(m)}\right) \\
& =\sum_{0 \leqslant l_{t} \leqslant p-1,0 \leqslant t \leqslant k-1}\left(\prod_{0 \leqslant m \leqslant k(p-1)-1}\binom{l_{k-1} p^{k-1}+l_{k-2} p^{k-2}+\cdots}{\alpha(m)_{k-1} p^{k-1}+\alpha(m)_{k-2} p^{k-2}+\cdots}\right) \\
& =\sum_{0 \leqslant l_{t} \leqslant p-1,0 \leqslant t \leqslant k-1}\left(\prod_{0 \leqslant m \leqslant k(p-1)-1}\binom{l_{k-1}}{\alpha(m)_{k-1}}\binom{l_{k-2}}{\alpha(m)_{k-2}} \cdots\binom{l_{0}}{\alpha(m)_{0}}\right) .
\end{aligned}
$$

We compute $c_{\alpha^{\prime}}$ from this identity as follows. Note that as $m$ varies from 0 to $k(p-1)-1, \alpha^{\prime}(m)$ takes on values $1, p, \ldots, p^{k-1}$ and that each value is taken precisely $p-1$ times. Therefore we get

$$
\prod_{0 \leqslant m \leqslant k(p-1)-1}\binom{l_{k-1}}{\alpha^{\prime}(m)_{k-1}}\binom{l_{k-2}}{\alpha^{\prime}(m)_{k-2}} \cdots\binom{l_{0}}{\alpha^{\prime}(m)_{0}}=l_{k-1}^{p-1} l_{k-2}^{p-1} \cdots l_{0}^{p-1} .
$$

Therefore $c_{\alpha^{\prime}}=\sum_{0 \leqslant l_{t} \leqslant p-1,0 \leqslant t \leqslant k-1} p_{k-1}^{p-1} p_{k-2}^{p-1} \cdots l_{0}^{p-1}=(-1)^{k} \neq 0$ by Lemma 1 .
To prove the second statement assume that $c_{\alpha} \neq 0$ (and $w_{\alpha} \notin I_{j-1}$ ). We have already observed that $\alpha(m) \leqslant p^{k-1}$ for all $0 \leqslant m \leqslant k(p-1)-1$. In fact, the inequality $\alpha(m)-p^{a_{m}} \leqslant 0$ for $0 \leqslant m \leqslant k(p-1)-1$ tells us more: For $m \leqslant(k-1)(p-1)-1$ we have $a_{m} \leqslant k-2$ and therefore $\alpha(m) \leqslant p^{k-2}$. Putting all this information together, we see that $\alpha(m)_{k-1} \leqslant 1$ for $0 \leqslant m \leqslant k(p-1)-1$ and $\alpha(m)_{k-1}=0$ for $0 \leqslant m \leqslant(k-1)(p-1)-1$. Now we arrange the terms in $c_{\alpha}$ to get

$$
c_{\alpha}=A \cdot \sum_{0 \leqslant l_{k-1} \leqslant p-1}\left(\prod_{0 \leqslant m \leqslant k(p-1)-1}\binom{l_{k-1}}{\alpha(m)_{k-1}}\right),
$$

where

$$
A=\sum_{0 \leqslant l_{t} \leqslant p-1,0 \leqslant t \leqslant k-2}\left(\prod_{0 \leqslant m \leqslant k(p-1)-1}\binom{l_{k-2}}{\alpha(m)_{k-2}} \cdots\binom{l_{0}}{\alpha(m)_{0}}\right) .
$$

Since $\alpha(m)_{k-1}=0$ for $0 \leqslant m \leqslant(k-1)(p-1)-1$, we have

$$
c_{\alpha}=A \cdot \sum_{0 \leqslant l_{k-1} \leqslant p-1}\left(\prod_{(k-1)(p-1) \leqslant m \leqslant k(p-1)-1}\binom{l_{k-1}}{\alpha(m)_{k-1}}\right) .
$$

On the other hand, since $\alpha(m)_{k-1}$ is at most one for $(k-1)(p-1) \leqslant m \leqslant k(p-1)-1$ we get

$$
\prod_{(k-1)(p-1) \leqslant m \leqslant k(p-1)-1}\binom{l_{k-1}}{\alpha(m)_{k-1}}= \begin{cases}l_{k}^{p-1} & \text { if } \alpha(m)_{k-1}=1 \text { for }(k-1)(p-1) \leqslant m \\ g & \text { otherwise },\end{cases}
$$

where $g$ is a polynomial of degree strictly less than $p-1$ (as a polynomial in $l_{k-1}$ ). Since $c_{\alpha} \neq 0$, it follows from Lemma 1 that $\alpha(m)_{k-1}=1$ for $(k-1)(p-1) \leqslant m$. So $\alpha(m)=p^{a_{m}}$ for $(k-1)(p-1) \leqslant m$ or equivalently $\alpha(m)=p^{k-1}$ for $(k-1)(p-1) \leqslant m$. We determine the rest of the coordinates of $\alpha$ along the same way. From $c_{\alpha} \neq 0$ we have $A \neq 0$. Since $\alpha(m)=p^{k-1}$ for $(k-1)(p-1) \leqslant m$, it follows that $\alpha(m)_{k-2}=\alpha(m)_{k-3}=\cdots=\alpha(m)_{0}=0$ for $(k-1)(p-1) \leqslant m$. Therefore we get

$$
A=\sum_{0 \leqslant l_{t} \leqslant p-1,0 \leqslant t \leqslant k-2}\left(\prod_{0 \leqslant m \leqslant(k-1)(p-1)-1}\binom{l_{k-2}}{\alpha(m)_{k-2}} \cdots\binom{l_{0}}{\alpha(m)_{0}}\right) .
$$

The argument that was used to compute $\alpha(m)$ for $(k-1)(p-1) \leqslant m$ applies to $\alpha(m)$ for $(k-2)(p-1) \leqslant m \leqslant(k-1)(p-1)-1$ as well because from the condition $\alpha(m)-p^{a_{m}} \leqslant 0$, we get that $\alpha(m) \leqslant p^{k-2}$ for $m \leqslant(k-1)(p-1)-1$ and that $\alpha(m) \leqslant p^{k-3}$ for $m \leqslant(k-2)(p-1)-1$. Repeating this argument and losing $l_{t}$ at each step for $0 \leqslant t \leqslant k-2$, one gets that $\alpha(m)=p^{a_{m}}$ for $0 \leqslant m \leqslant$ $k(p-1)-1$. Hence $\alpha=\alpha^{\prime}$ as desired.

Lemma 6. Let $v_{1}=(0, \ldots, 0, b, a)^{t}$ and $v_{2}=(0, \ldots, 0, b, c)^{t}$ be two vectors in $V_{n}$ in different $G$-orbits. Then $N_{G}\left(x_{n}\right)$ separates $v_{1}$ and $v_{2}$.

Proof. Note that $N_{G}\left(x_{n}\right)\left(v_{1}\right)=\left(\prod_{0 \leqslant l \leqslant p^{r}-1} \sigma^{l}\left(x_{n}\right)\right)\left(v_{1}\right)=\prod_{0 \leqslant 1 \leqslant p^{r}-1} x_{n}\left(\sigma^{l}\left(v_{1}\right)\right)=\prod_{0 \leqslant 1 \leqslant p^{r}-1}(a+l b)$ $=\left(\prod_{0 \leqslant 1 \leqslant p-1} a+l b\right)^{p^{r-1}}$. Similarly, we have $N_{G}\left(x_{n}\right)\left(v_{2}\right)=\left(\prod_{0 \leqslant 1 \leqslant p-1} c+l b\right)^{p^{r-1}}$. Since taking $p$ th powers is one to one in $F$, it suffices to show that $\prod_{0 \leqslant 1 \leqslant p-1}(a+l b) \neq \prod_{0 \leqslant l \leqslant p-1}(c+l b)$. Note that $a \neq c$ because $v_{1} \neq v_{2}$. Therefore we may assume that $b \neq 0$, because otherwise $\prod_{0 \leqslant 1 \leqslant p-1}(a+l b)=a^{p} \neq$
$c^{p}=\prod_{0 \leqslant 1 \leqslant p-1}(c+l b)$. We define a polynomial $Q(x)=\prod_{0 \leqslant 1 \leqslant p-1}(x+l b) \in F[x]$. We have $Q(a)=$ $\prod_{0 \leqslant 1 \leqslant p-1}(a+l b)$ and $Q(c)=\prod_{0 \leqslant 1 \leqslant p-1}(c+l b)$. Notice also that $Q(a)=Q(a+b)=Q(a+2 b)=\cdots=$ $Q(a+(p-1) b)$. Hence $a, a+b, \ldots, a+(p-1) b$ is a set of distinct roots to the equation $Q(x)=Q(a)$. It follows that these are the only roots because $Q(x)$ is a polynomial of degree $p$. Therefore if $Q(a)=Q(c)$, then we have $c=a+t b$ for some $0 \leqslant t \leqslant p-1$, or equivalently $\sigma^{t}\left(v_{1}\right)=v_{2}$. This is a contradiction because $v_{1}$ and $v_{2}$ are in different orbits.

Theorem 7. Let $1<n \leqslant p^{r}$ be an integer and $S \subseteq F\left[V_{n-1}\right]^{G}$ be a separating set for $V_{n-1}$, then $S$ together with $N_{G}\left(x_{n}\right)$ and $H_{j, n}$ for $1 \leqslant j \leqslant n-2$ is a separating set for $V_{n}$.

Proof. Let $v_{1}=\left(c_{1}, c_{2}, \ldots, c_{n}\right)^{t}$ and $v_{2}=\left(d_{1}, d_{2}, \ldots, d_{n}\right)^{t}$ be two vectors in $V_{n}$ in different $G$-orbits. If $\left(c_{1}, c_{2}, \ldots, c_{n-1}\right)^{t}$ and $\left(d_{1}, d_{2}, \ldots, d_{n-1}\right)^{t}$ are in different $G$-orbits in $V_{n-1}$, then there exists a polynomial in $S$ that separates these vectors by assumption. Hence this polynomial separates $v_{1}$ and $v_{2}$ as well. Therefore we may assume that $c_{i}=d_{i}$ for $1 \leqslant i \leqslant n-1$ by replacing $\left(d_{1}, d_{2}, \ldots, d_{n-1}\right)^{t}$ with a suitable element in its orbit. So we have $c_{n} \neq d_{n}$. First assume that there exists an integer $1 \leqslant j \leqslant n-2$ such that $c_{j}=d_{j} \neq 0$. We may also assume that $j$ is the smallest such integer. We show that $H_{j, n}$ separates $v_{1}$ and $v_{2}$ as follows. Assume the notation of Lemma 3. Since $c_{i}=d_{i}=0$ for $i \leqslant j-1$, by Lemma 3 it is enough to show that $N_{G_{r-k}}\left(x_{n}\right) \operatorname{Tr}_{G_{r-k}}^{G}(X)+f$ separates $v_{1}$ and $v_{2}$. But since $f \in F\left[x_{1}, \ldots, x_{n-1}\right]$, we have $f\left(v_{1}\right)=f\left(v_{2}\right)$. Moreover, by Lemmas 4 and 5 we get $\operatorname{Tr}_{G_{r-k}}^{G}(X)\left(v_{1}\right)=\operatorname{Tr}_{G_{r-k}}^{G}(X)\left(v_{2}\right)=c_{\alpha^{\prime}} c_{j}^{p^{r-k} k(p-1)} \neq 0$. It follows that we just need to show that $N_{G_{r-k}}\left(x_{n}\right)$ separates $v_{1}$ and $v_{2}$. If $n-j \neq p^{k}$, then by Lemma 2 we have $N_{G_{r-k}}\left(x_{n}\right) \equiv x_{n}^{p^{r-k}}$ and this polynomial separates $v_{1}$ and $v_{2}$ because the last coordinates of $v_{1}$ and $v_{2}$ are different. If $n-j=p^{k}$, then we have $\sigma^{p^{k}}\left(e_{j}\right)=e_{j}+e_{n}$. So the basis vectors $e_{n}, e_{j}$ span a two-dimensional representation of $G_{r-k}$. Moreover, since $v_{1}, v_{2}$ are in different $G$-orbits, $c_{j} e_{j}+c_{n} e_{n}$ and $c_{j} e_{j}+d_{n} e_{n}$ are also in different $G_{r-k^{-}}$ orbits. The reason for this is that the basis elements $e_{j+1}, e_{j+2}, \ldots, e_{n}=e_{j+p^{k}}$ are fixed by $\sigma^{p^{k}}$ and therefore $\sigma^{l p^{k}}\left(c_{j} e_{j}+d_{n} e_{n}\right)=c_{j} e_{j}+c_{n} e_{n}$ for some $l$ implies that

$$
\sigma^{l p^{k}}\left(v_{2}\right)=\sigma^{l p^{k}}\left(c_{j} e_{j}+c_{j+1} e_{j+1}+\cdots+d_{n} e_{n}\right)=c_{j} e_{j}+c_{j+1} e_{j+1}+\cdots+c_{n} e_{n}=v_{1}
$$

which contradicts the fact that $v_{1}$ and $v_{2}$ are in different $G$-orbits. Hence by the previous lemma (applied to the group $G_{r-k}$ ) we see that $N_{G_{r-k}}\left(x_{n}\right)$ separates $c_{j} e_{j}+c_{n} e_{n}$ and $d_{j} e_{j}+c_{n} e_{n}$ because the $i$ th coordinate is zero for $i \leqslant j-1$ in these vectors. But no variable in $\left\{x_{j+1}, \ldots, x_{n-1}\right\}$ appears in $N_{G_{r-k}}\left(x_{n}\right)$. It follows that $N_{G_{r-k}}\left(x_{n}\right)$ separates $v_{1}$ and $v_{2}$ as well.

Finally, if $c_{i}=d_{i}=0$ for $1 \leqslant i \leqslant n-2$, then $N_{G}\left(x_{n}\right)$ separates $v_{1}$ and $v_{2}$ by the previous lemma.
By induction, our theorem provides an explicit separating set for $V_{n}$.
Corollary 8. The polynomials $N_{G}\left(x_{i}\right)$ for $1 \leqslant i \leqslant n$ together with $H_{a, b}$ for $1 \leqslant a \leqslant b-2$ and $1 \leqslant b \leqslant n$ form a separating set for $V_{n}$.

## Acknowledgments

I thank the referees very much for carefully reading the manuscript and many useful remarks. In particular, I am grateful to the suggestion to use the lower triangular Jordan Normal Form which led to a more explicit listing of the polynomials in the separating set our results provide for $V_{n}$. This greatly improved the exposition.
