Abstract: A strategically new approach to cyclopentene[*c*]chroman-2-ones and cyclopent-1-enecarboxylates by tandem Michael–Horner–Wadsworth–Emmons reaction of 2,5-hexanedione with 3-(diethoxyphosphoryl)coumarins is described. The products were obtained as single diastereoisomers in high yields.

Key words: Michael addition, Horner–Wadsworth–Emmons olefination, tandem reaction, annulations, 1,5,7-triazabicyclo[4.4.0]dec-5-ene

The cyclopent-1-enecarboxylate moiety is present in many biologically active natural products.[1] Within this class of compounds the cyclopenta[*c*]tetrahydropyran-2-one ring system is incorporated in the reduced or modified form into natural products such as neonepetalactone (**1**),[2a] mitsugashiwalactone (**2**), onikulactone (**3**),[2b] herbertenolide (**4**),[2c] aflatoxin B (**5**), and aflatoxin M (**6**)[2d] (Figure 1) which have been shown to possess diverse biological properties.

In recent years considerable research activity has been directed toward the synthesis of cyclopentene-fused chroman-2-ones. The synthetic strategies include [3+2] cycloaddition of allenoates with 3-alkoxycarbonylcoumarin,[3a] intramolecular [3+2] cycloaddition of 2-styrenyl allenoates,[3b] annulation of 3-acetylcoumarin with allenylboronic esters,[3c] and [3+2] cycloaddition of 3-acetylcoumarin with cyclopropenone acetals.[3d] Palladium-catalyzed [3+2] cycloaddition of 2-(trimethylsilylmethyl)-allyl acetates with coumarins has been used to install a cyclopentane ring containing an *exo*-methylene group.[3e]

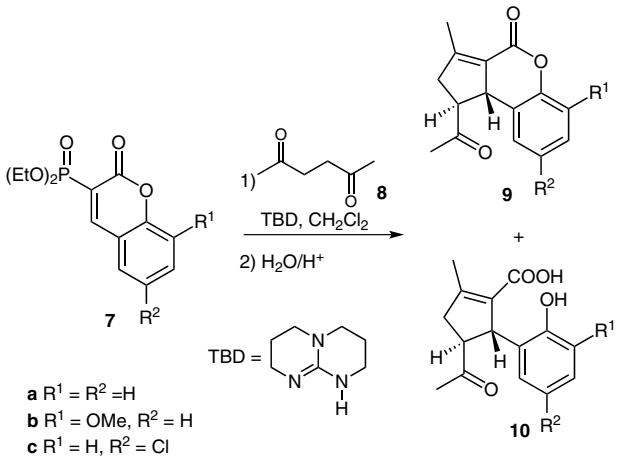
Despite its potential utility, the approach based on a Michael addition of homoenolate anion equivalents to α-dialkoxyphosphoryl-α,β-unsaturated lactones followed by an intramolecular Horner–Wadsworth–Emmons (HWE) reaction of the resulting 2-phosphono-6-oxoalkanoates has been exploited only rarely for the preparation of cyclopentene annulated γ- and δ-lactones. Minami et al. reported that the tandem Michael–intramolecular HWE reaction of diethyl 2-oxoalkylmalonates with α-phosphoryl-α,β-unsaturated-γ-lactones provided cyclopentene-fused γ-lactones.[4a] Bestmann et al. reported that Michael addition of [2-(1,3-dioxolan-2-yl)ethyl]magnesium bromide to 3-(diethoxyphosphoryl)coumarin followed by deprotection of the aldehyde group and an intramolecular HWE reaction led to cyclopentene-annulated chromanones.[4b] In the course of our earlier studies we have reported that the above [3+2] annulation strategy could be extended for the preparation cyclopent-1-enecarboxylates from the corresponding *tert*-butyl (*E*)-2-(diethoxyphosphoryl)alk-2-enoates.[4c]

In spite of these advances, it is evident that methods to access cyclopentannulated lactones, particularly via conceptually different approaches are still of significant interest. It is worthy of note that 1,4-diketones are known to be potent homoenolate equivalents.[5a] Surprisingly, a strategy for [3+2] cyclopentannulation that utilizes homoenolates generated from 1,4-diketones (γ-oxoketone enolates) as three-carbon fragments has not been exploited.[5]

In this letter we report the first examples of a tandem Michael–intramolecular HWE reaction of 2,5-hexanedione (**8**) with 3-(diethoxyphosphoryl)coumarins **7a**–**c** in which the dione serves as a γ-oxoketone enolate equivalent. This approach expands greatly the scope of the conjugate addition involving coumarins **7**[6] and provides a new and prac-

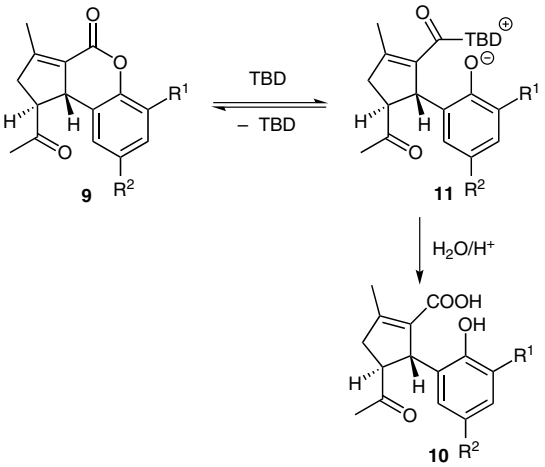
tical entry into cyclopentene-fused chromanones **9a–c** and cyclopentenecarboxylates **10a–c** and **12a–c**.

Successful development of the reaction sequence required identification of bases that could be used for the enolate generation. After screening of a range of organic and inorganic bases, 1,5,7-triazabicyclo[4.4. 0]dec-5-ene (TBD) was found to be the optimal choice. The reaction of 3-(diethoxyphosphoryl)coumarin **7a** with dione **8** (3 equiv) in the presence of a stoichiometric quantity of TBD proceeded efficiently in CH_2Cl_2 at room temperature and was complete within one day (Scheme 1). ^{31}P NMR spectroscopic analysis of the crude reaction mixture indicated complete consumption of the coumarin **7a** and revealed the presence of one signal in the phosphate region (δ = 1.4 ppm). After acidic quench the product was isolated as a mixture of *trans*-lactone **9a** accompanied by the corresponding hydroxyacid *trans*-**10a** in a ca. 1:1 ratio. Both compounds could be efficiently separated by column chromatography in 36% and 37% yield, respectively. Dehydration of the hydroxyacid **10a** using TFAA (1 equiv) in CH_2Cl_2 at room temperature provided the lactone **9a** in an excellent yield of 97%. Notably, treatment of the crude mixture of **9a** and **10a** obtained with TFAA (1 equiv) in CH_2Cl_2 at room temperature for three hours resulted in complete lactonization of **10a** to **9a**, which was isolated by chromatography as the sole product in 73% yield. The coumarins **7b** and **7c**, regardless of the presence of electron-withdrawing or electron-donating substituents on the aromatic ring, participated in this process with high efficiency. The crude products were formed as the mixtures of the *trans*-lactones **9b**,**c** and the corresponding *trans*-hydroxyacids **10b**,**c** in a 1:1 ratio. Without purification these mixtures were subjected to dehydratation to yield the *trans*-lactones **9b** and **9c** in 75% and 69% yields, respectively.

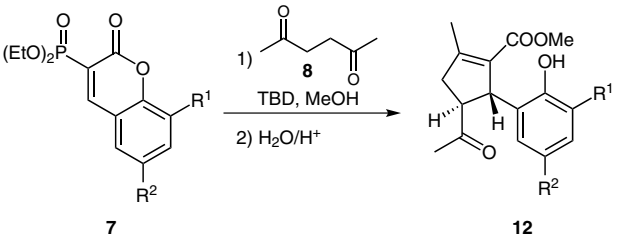


Scheme 1 The reaction pathway in dichloromethane

From a mechanistic point of view it is reasonable to assume that the formation of hydroxy acids **10a–c** occurs in a stepwise fashion by initial formation of the lactones **9a–c** followed by their hydrolysis catalyzed by TBD[7] (Scheme 2). Addition of TBD to the carbonyl group of the lactones **9a–c** results in the formation of acylammonium salts **11a–c**, which in the presence of water are easily converted into the corresponding carboxylic acids **10a–c**. Consequently, it was reasoned that, in the presence of a protic solvent used as both reagent and solvent, the reaction would be driven toward the formation of cyclopentenecarboxylates. Indeed, reaction of coumarins **7a–c** with dione **8** and TBD in methanol (Scheme 3) resulted in the efficient formation of methyl *trans*-cyclopentenecarboxylates **12a–c** in 80%, 81% and 77% yield, respectively, as the sole products.



Scheme 2 Lactone hydrolysis catalyzed by TBD



Scheme 3 The reaction pathway in methanol

The *trans* relative configuration of the products **9**, **10**, and **12** was established by single-crystal X-ray analysis conducted on cyclopentene[*c*]chroman-2-one **9c**[8] (Figure 2).

The *anti* diastereoselectivity in the Michael addition step leading to the formation of the dihydrocoumarins **14** is in accord with the results of our previous studies[6] concerning the conjugate addition of secondary enamines, derived from cycloalkanones and benzylamine, to coumarin **7a**. The reaction is proposed to occur via a synclinal acyclic transition state **13** in which the *Si** face of the enolate approaches the *Re** face of the coumarin (Scheme 4).

In conclusion, we have developed the first tandem Michael–intramolecular HWE reaction of 2,5-hexanedione with 3-(diethoxyphosphoryl)coumarins. The method represents a new approach to functionalized cyclopentene[*c*]chromanones and cyclopent-1-enecarboxylates which should be widely useful because it is a simple and

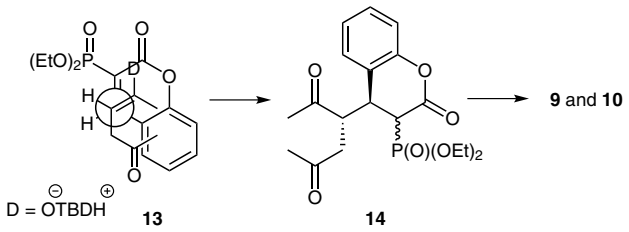

Scheme 4 Proposed model for the TBD-promoted Michael reaction between coumarin **7** and 2,5-hexanedione

fully diastereoselective C–C forming process. It demonstrates the previously unrecognized property of 2,5-hexanedione as homoenolate anion equivalent.
