#### Abstract

It is proved that there are triangle-free intersection graphs of line segments in the plane with arbitrarily small ratio between the maximum size of an independent set and the total number of vertices.

Keywords Intersection graph • Line segments • Triangle-free • Maximum independent set • Fractional chromatic number

## 1 Introduction

Pawlik et al. [7] proved that there are triangle-free intersection graphs of line segments in the plane with arbitrarily large chromatic number. The graphs they construct have independent sets containing more than $1 / 3$ of all the vertices. It has been left open whether there is a constant $c>0$ such that every triangle-free intersection graph of $n$ segments in the plane has an independent set of size at least $c n$. Fox and Pach [3] conjectured a much more general statement, that $K_{k}$-free intersection graphs of curves in the plane have linear-size independent sets, for every $k$. This would imply a wellknown conjecture that $k$-quasi-planar graphs (graphs drawn in the plane so that no $k$ edges cross each other) have linearly many edges [5], which is proved up to $k=4$ [1].

In this note, I resolve the independent set problem in the negative, proving the following strengthening of the result of Pawlik et al.:

Theorem There are triangle-free segment intersection graphs with arbitrarily small ratio between the maximum size of an independent set and the total number of vertices.

[^0]The constructions presented in the next two sections give rise to triangle-free intersection graphs of $n$ segments in the plane with maximum independent set size $\Theta(n / \log \log n)$.

## 2 Construction

Pawlik et al. [7] construct, for $k \geqslant 1$, a triangle-free graph $G_{k}$ and a family $\mathcal{P}_{k}$ of subsets of $V\left(G_{k}\right)$, called probes, with the following properties:
(i) $\left|\mathcal{P}_{k}\right|=2^{2^{k-1}-1}$,
(ii) every member of $\mathcal{P}_{k}$ is an independent set of $G_{k}$,
(iii) for every proper coloring of the vertices of $G_{k}$, there is a probe $P \in \mathcal{P}_{k}$ such that at least $k$ colors are used on the vertices in $P$.

They are built by induction on $k$, as follows. The graph $G_{1}$ has just one vertex $v$, and $\mathcal{P}_{1}$ has just one probe $\{v\}$. For $k \geqslant 2$, first, a copy $(G, \mathcal{P})$ of $\left(G_{k-1}, \mathcal{P}_{k-1}\right)$ is taken. Then, for every probe $P \in \mathcal{P}$, another copy $\left(G_{P}, \mathcal{P}_{P}\right)$ of $\left(G_{k-1}, \mathcal{P}_{k-1}\right)$ is taken. There are no edges between vertices from different copies. Finally, for every probe $P \in \mathcal{P}$ and every probe $Q \in \mathcal{P}_{P}$, a new vertex $d_{Q}$ connected to all vertices in $Q$, called the diagonal of $Q$, is added. The resulting graph is $G_{k}$. The family of probes $\mathcal{P}_{k}$ is defined by

$$
\mathcal{P}_{k}=\left\{P \cup Q: P \in \mathcal{P} \text { and } Q \in \mathcal{P}_{P}\right\} \cup\left\{P \cup\left\{d_{Q}\right\}: P \in \mathcal{P} \text { and } Q \in \mathcal{P}_{P}\right\} .
$$

It is easy to check that the graph $G_{k}$ is indeed triangle-free and the conditions (i)-(iii) are satisfied for $\left(G_{k}, \mathcal{P}_{k}\right)$-see [7] for details. It is also shown in [7] how the graph $G_{k}$ is represented as a segment intersection graph.

I will show that there is an assignment $w_{k}$ of positive integer weights to the vertices of $G_{k}$ with the following properties:
(iv) the total weight of $G_{k}$ is $\frac{k+1}{2} \cdot 2^{2^{k-1}-1}$,
(v) for every independent set $I$ of $G_{k}$, the number of probes $P \in \mathcal{P}_{k}$ such that $P \cap I \neq \emptyset$ is at least the weight of $I$.

Once this is achieved, the proof of the theorem of this paper follows easily. Namely, it follows from (i) and (v) that every independent set $I$ of $G_{k}$ has weight at most $2^{2^{k-1}-1}$. We can take the representation of $G_{k}$ as a segment intersection graph and replace every segment representing a vertex $v \in V\left(G_{k}\right)$ by $w_{k}(v)$ parallel segments lying very close to each other, so as to keep the property that any two segments representing vertices $u, v \in V\left(G_{k}\right)$ intersect if and only if $u v \in E\left(G_{k}\right)$. It follows from (iv) that the family of segments obtained this way has size $\frac{k+1}{2} \cdot 2^{2^{k-1}-1}$, while every independent set of its intersection graph has size at most $2^{2^{k-1}-1}$.

The assignment $w_{k}$ of weights to the vertices of $G_{k}$ is defined by induction on $k$, following the inductive construction of $\left(G_{k}, \mathcal{P}_{k}\right)$. The weight of the only vertex of $G_{1}$ is set to 1 . This clearly satisfies (iv) and (v). For $k \geqslant 2$, let $G, \mathcal{P}, G_{P}, \mathcal{P}_{P}$ and $d_{Q}$ be defined as in the inductive step of the construction of $\left(G_{k}, \mathcal{P}_{k}\right)$. Let $p=\left|\mathcal{P}_{k-1}\right|=$ $2^{2^{k-2}-1}$. The weights $w_{k}$ of the vertices of $G$ are their original weights $w_{k-1}$ in $G_{k-1}$ multiplied by $p$. The weights $w_{k}$ of the vertices of every $G_{P}$ are equal to their original
weights $w_{k-1}$ in $G_{k-1}$. The weight $w_{k}$ of every diagonal $d_{Q}$ is set to 1 . It remains to prove that (iv) and (v) are satisfied for $\left(G_{k}, \mathcal{P}_{k}, w_{k}\right)$ assuming that they hold for $\left(G_{k-1}, \mathcal{P}_{k-1}, w_{k-1}\right)$.

The proof of (iv) is straightforward:

$$
w_{k}\left(G_{k}\right)=w_{k}(G)+\sum_{P \in \mathcal{P}}\left(w_{k}\left(G_{P}\right)+\left|\mathcal{P}_{P}\right|\right)=2 p w_{k-1}\left(G_{k-1}\right)+p^{2}=\frac{k+1}{2} \cdot 2^{2^{k-1}-1}
$$

For the proof of (v), let $I$ be an independent set in $G_{k}$. Let $\mathcal{I}=\{P \in \mathcal{P}: P \cap I \neq \emptyset\}$. For every probe $P \in \mathcal{P}$, define

$$
\begin{array}{ll}
\mathcal{I}_{P}=\left\{Q \in \mathcal{P}_{P}: Q \cap I \neq \emptyset\right\}, & \mathcal{P}_{P}^{\prime}=\left\{P \cup Q: Q \in \mathcal{P}_{P}\right\} \cup\left\{P \cup\left\{d_{Q}\right\}: Q \in \mathcal{P}_{P}\right\}, \\
D_{P}=\left\{d_{Q}: Q \in \mathcal{P}_{P}\right\}, & \mathcal{I}_{P}^{\prime}=\left\{P^{\prime} \in \mathcal{P}_{P}^{\prime}: P^{\prime} \cap I \neq \emptyset\right\}
\end{array}
$$

By the induction hypothesis, we have

$$
w_{k}(V(G) \cap I) \leqslant p|\mathcal{I}|, \quad w_{k}\left(V\left(G_{P}\right) \cap I\right) \leqslant\left|\mathcal{I}_{P}\right|
$$

Suppose $P \in \mathcal{I}$. It follows that $(P \cup Q) \cap I \neq \emptyset$ and $\left(P \cup\left\{d_{Q}\right\}\right) \cap I \neq \emptyset$ for every $Q \in \mathcal{P}_{P}$. Hence $\left|\mathcal{I}_{P}^{\prime}\right|=\left|\mathcal{P}_{P}^{\prime}\right|=2 p$. Moreover, we have $d_{Q} \notin I$ whenever $Q \in \mathcal{I}_{P}$, because $d_{Q}$ is connected to all vertices in $Q$, one of which belongs to $I$. Hence

$$
w_{k}\left(V\left(G_{P}\right) \cap I\right)+w_{k}\left(D_{P} \cap I\right) \leqslant\left|\mathcal{I}_{P}\right|+\left|\mathcal{P}_{P} \backslash \mathcal{I}_{P}\right|=\left|\mathcal{P}_{P}\right|=p
$$

Now, suppose $P \in \mathcal{P} \backslash \mathcal{I}$. If $Q \in \mathcal{I}_{P}$, then $(P \cup Q) \cap I \neq \emptyset, d_{Q} \notin I$ (by the same argument as above), and $\left(P \cup\left\{d_{Q}\right\}\right) \cap I=\emptyset$. If $Q \in \mathcal{P}_{P} \backslash \mathcal{I}_{P}$, then $(P \cup Q) \cap I=\emptyset$, and $\left(P \cup\left\{d_{Q}\right\}\right) \cap I \neq \emptyset$ if and only if $d_{Q} \in I$. Hence

$$
w_{k}\left(V\left(G_{P}\right) \cap I\right)+w_{k}\left(D_{P} \cap I\right) \leqslant\left|\mathcal{I}_{P}\right|+\left|D_{P} \cap I\right|=\left|\mathcal{I}_{P}^{\prime}\right|
$$

To conclude, we gather all the inequalities and obtain

$$
\begin{aligned}
w_{k}(I) & =w_{k}(V(G) \cap I)+\sum_{P \in \mathcal{P}}\left(w_{k}\left(V\left(G_{P}\right) \cap I\right)+w_{k}\left(D_{P} \cap I\right)\right) \\
& \leqslant p|\mathcal{I}|+\sum_{P \in \mathcal{I}} p+\sum_{P \in \mathcal{P} \backslash \mathcal{I}}\left|\mathcal{I}_{P}^{\prime}\right|=\sum_{P \in \mathcal{I}}\left|\mathcal{I}_{P}^{\prime}\right|+\sum_{P \in \mathcal{P} \backslash \mathcal{I}}\left|\mathcal{I}_{P}^{\prime}\right|=\sum_{P \in \mathcal{P}}\left|\mathcal{I}_{P}^{\prime}\right| .
\end{aligned}
$$

## 3 Improved Construction

Pawlik et al. [7] define also a graph $\tilde{G}_{k}$, which arises from $\left(G_{k}, \mathcal{P}_{k}\right)$ by adding, for every probe $P \in \mathcal{P}_{k}$, a diagonal $d_{P}$ connected to all vertices in $P$. This is the smallest triangle-free segment intersection graph known to have chromatic number greater than $k$. Define the assignment $\tilde{w}_{k}$ of weights to the vertices of $\tilde{G}_{k}$ so that $\tilde{w}_{k}$ is equal to $w_{k}$ on the vertices of $G_{k}$ and $\tilde{w}_{k}\left(d_{P}\right)=1$ for every $P \in \mathcal{P}_{k}$. Let $I$ be an independent set in $\tilde{G}_{k}$. Let $\mathcal{I}=\left\{P \in \mathcal{P}_{k}: P \cap I \neq \emptyset\right\}$. Hence $d_{P} \notin I$ for $P \in \mathcal{I}$. It follows that

$$
\begin{aligned}
\tilde{w}_{k}(I) & =w_{k}\left(V\left(G_{k}\right) \cap I\right)+\left|\left\{d_{P}: P \in \mathcal{P}_{k}\right\} \cap I\right| \\
& \leqslant|\mathcal{I}|+\left|\mathcal{P}_{k} \backslash \mathcal{I}\right|=\left|\mathcal{P}_{k}\right|=2^{2^{k-1}-1}, \\
\tilde{w}_{k}\left(\tilde{G}_{k}\right) & =w_{k}\left(G_{k}\right)+\left|\mathcal{P}_{k}\right|=\frac{k+3}{2} \cdot 2^{2^{k-1}-1}
\end{aligned}
$$

The graph $\tilde{G}_{k}$ is the smallest one for which I can prove that it has a weight assignment such that the ratio between the maximum weight of an independent set and the total weight is at most $\frac{2}{k+3}$. It is not difficult to prove (e.g. using weak LP duality) that the assignment of weights $\tilde{w}_{k}$ to the vertices of $\tilde{G}_{k}$ is optimal (gives the least ratio) for this particular graph.

Both constructions give rise to triangle-free intersection graphs of $n$ segments in the plane with maximum independent set size $\Theta(n / \log \log n)$. On the other hand, it follows from the result of McGuinness [4] that every triangle-free intersection graph of $n$ segments has chromatic number $O(\log n)$ and maximum independent set size $\Omega(n / \log n)$.

## 4 Other Geometric Shapes

It is known that the graphs $G_{k}$ and $\tilde{G}_{k}$ have intersection models by many other geometric shapes, for example, L-shapes, axis-parallel ellipses, circles, axis-parallel square boundaries [6] or axis-parallel boxes in $\mathbb{R}^{3}$ [2]. The result of this paper can be extended to those models for which every geometric object $X$ representing a vertex of the intersection graph can be replaced by many pairwise disjoint objects approximating $X$. This is possible, for example, for intersection graphs of L-shapes, circles or axisparallel square boundaries, but not for intersection graphs of axis-parallel ellipses or axis-parallel boxes in $\mathbb{R}^{3}$. The problem whether triangle-free intersection graphs of the latter kind of shapes have linear-size independent sets remains open.
