

SCIENTIFIC COUNCIL MEETING – JUNE 2022

Effect in survey indices of removing stations in the NAFO closed Areas in the design of the EU surveys including the 2021 closed areas

by

Abstract

In 2009, the Fisheries Commission established several coral and sponges protection closures areas to bottom fisheries within the NAFO Regulatory Area that started to be applied in 2010. Three random bottom trawl surveys are performed by the EU yearly in the NAFO Regulatory Area: Spanish Div. 3NO (Spring), Spanish and Portuguese in Div. 3M (Summer) and Spanish Div. 3L (Summer). The surveys are currently carried out by the R/V *Vizconde de Eza* and covers the closed areas. A study of the survey indices of the species assessed in NAFO (except shrimp) have been performed to know the impact of removing the hauls in the closed areas from the survey.

The results of the analysis show that there are two species, Greenland halibut and roughhead grenadier, in which their biomass and/or age/length indices are affected in all the surveys analyzed. This is due to the fact that these two species are distributed at greater depths and that the closed areas are mainly found in deep areas, so the suppression of survey hauls in closed areas has a greater impact on the indices of these two species. The best way to know the impact in the assessment results of these changes in the Greenland halibut and roughhead grenadier indices would be to run the assessment with both indices, the base case ones and the new case ones, and compare the results.

There are other species in which their global biomass indices do not change very much, but their age or length indices change appreciably when hauls from closed areas are removed from the calculations. In one case, the results of the assessment are compromised and it would be better to rerun the assessment with the new case indices to see the differences. In other cases, although the length distribution is not directly used in the assessment models, some recruitment and spawning stock biomass indices are derived from them, so changes in the perception of the stock could be encountered. These changes in the age/length indices should be considered in future assessments of these stocks if the prohibition of the surveys trawls in closed areas is approved.

If more close areas are added in the future to the existing ones, this study should be redone, which implies a big amount of work. It is not worth to rerun this study each time the closed areas change.

Introduction

In 2008, the WGESA (formerly WGEAFM), was created with the aim to help Scientific Council in conducting NAFO into an Ecosystem Approach (EA) to Fisheries following the guidelines made by the FAO in 2003 (FAO, 2003). The purpose of an ecosystem approach to fisheries is to plan, develop and manage fisheries in a manner that addresses the multiple needs and desires of societies, without jeopardizing the options for future generations to benefit from the full range of goods and services provided by marine ecosystems. In 2009, the Fisheries Commission established several coral and sponges protection closures areas to bottom fisheries within the NAFO Regulatory Area that started to be applied in 2010. Currently, 18 area closures are in force in the NRA (Figure 1), including 4 areas added in September 2021 after a reassessment of the closures requested by the Commission to the Scientific Council by 2020, being performed by the WGESA in November 2020. A previous work was submitted as SCR in September 2021 without those last 4 areas (González-Troncoso *et al.*, 2021). This study is the update of that work with the 18 closures.

EU (Portugal and Spain) have performed a series of trawl surveys in NAFO Regulatory Area Divs. 3NO (since 1995), in Div. 3L (since 2003) and in Div. 3M (since 1988). These surveys have a stratified design over the total area of the Divisions and the number of random hauls in each stratum is proportional to the stratum area. The location of the survey hauls can eventually be inside of the closed areas. They were designed prior to implementation of any closed area and provide crucial data for several fish stock assessments, as well as have provided significant if not the bulk of the information for the knowledge and definition of the closed areas. In the last years, mostly since 2018, it has been tried not to perform hauls inside the closed areas to avoid harm to the VMEs.

During its 2015 meeting, EAFFM WG recommended that *SC considers options to expedite risk assessment of scientific trawl surveys impact on VME in closed areas, and the effect of excluding surveys from these areas on stock assessments*. In this paper, the consequences in the different survey indices of removing the closed areas from the design of the surveys are investigated.

Material and Methods

The EU surveys time series in the NAFO Regulatory Area (NRA) Div. 3LMNO were used in this study. A summary of the main characteristics of the surveys is in Table 1. Figure 1 shows the stratification of the NRA used during the surveys (Bishop, 1994). Figure 2 presents the position of the valid hauls during the whole time series (starting point of each haul). In 2020, only the 3M survey was carried out due to the COVID-19 pandemic. In 2021, the 3L survey was not performed for the same reason. In 2005, the 3L survey was not carried out due to technical problems with the vessel. Between 2004 and 2008, strata 526 and 527 of Division 3M were surveyed, but not after 2009 because of a high presence of sponges in the hauls performed in those strata. The hauls in those strata were omitted in this study.

In the case of the Div. 3NO and Div. 3M surveys, the vessel and/or the gear was changed in 2002 and 2004, respectively. The indices of the main species were transformed in both surveys to the new series (REFERENCES). For those surveys, all the years have been used for this analysis, but it was decided to work with the original series and not with the transformed series since the purpose of the study is to compare the series with and without closed areas. The indices before and after the change of the vessel are depicted separately in the Figures to avoid confusion in which indices are shown. In the case of the 3NO, in 2001 the data of the former vessel were used as the basis of the indices. In the 3L survey, all the years have been included although the coverage of the first two years (2003-2004) was very poor.

The hauls with the starting or ending point inside a closed area were considered to be performed inside the closed areas. New survey indices were estimated removing those hauls inside the closed areas. In Table 2, the stratification scheme and the area of each stratum, with and without the closed areas (calculated with the library *sf* of the R software) is presented by survey and Division. The potential impacts of excluding the closed areas from the surveys design were evaluated by comparing the time series of biomass with (base case) and without (new case) the hauls inside the closed areas. The new indices calculations were made for the species assessed by the NAFO Scientific Council (except shrimp, Table 3), and compared with the results with all the

hauls (González-Troncoso *et al.*, 2022; Garrido *et al.*, 2022; Román Marcote *et al.*, 2020a; Román Marcote *et al.*, 2020b).

In all the surveys, during the normal operations, there are some strata with only one valid haul (Tables 4A, 5A and 6A). This is normally due to lack of time, mainly because several hauls were performed but just one was valid and there was no time available for trying more locations. There are some cases, mainly at the beginning of the series, where some strata have no hauls (strata not surveyed). In the case of 3M and 3L (in this last case taking out the two first years), very few cases are presented, but in the 3NO it is more usual, mainly due to the characteristics of those Divisions, with several strata in the cliffs that are more difficult to trawl. In the case of the strata without hauls, no data is used to calculate the indices of those strata. In the case of the strata with one haul, the biomass and the length/age distribution were calculated with the available data of that haul. It must be noted that, in this case, the SD of that strata could not be calculated, so the total SD by year may be underestimated.

Potential time-varying biases created by the exclusion of data within the protected areas was explored by examining trends in the annual log of the ratio between the two time series (ratio = without the hauls in the closed area / with all the hauls, i.e. a value of 0 in the log ratio would mean that the indices with and without the closed areas are identical, negative values would indicate that removing the hauls in the closed areas renders lower index values than keeping all the hauls, and viceversa). We were particularly interested in the potential for time-varying biases as these may compromise the scientific advice produced from the surveys (see Benoît *et al.*, 2020; Rideout *et al.*, 2021). To that end, a generalized additive model (GAM) was fitted to the time series of log-ratio values. Significant results for the smoother for the covariate 'year' indicated the potential for a time varying bias. The p-value of the fit is presented in Table 2, indicating if the fit is or not significant, as well as the maximum difference in the biomass of both cases in percentage:

$$\text{Max Diff Biomass (\%)} = 100 - \frac{\text{biomass new case}}{\text{biomass old case}} * 100$$

Positive values of the maximum difference in the biomass means that the maximum biomass was in the new case, while negative values indicate that the maximum biomass was in the base case.

A study of the age distribution (or length distribution if ages are not available) was made for the species in Table 3, calculating the indices by age with and without the hauls inside the closed areas. When age distribution is presented, all the ages are displayed, except in the case of the redfish, for which the ages were grouped by 2. When only length distribution is available, the lengths were grouped in 16 groups in order to allow depicting properly the Tables and the Figures. Age/length distribution is presented only when obvious differences are presented in the biomass and/or if the bias of the gam fit is significant.

Results

The results are given by species and survey since they are the survey indexes that are used in the different stocks assessments.

Number of hauls

33 of the 95 strata of the NRA included in the surveys have some surface belonging to some closed area (Table 2).

Division 3M survey

18 out of 32 strata surveyed during the Div. 3M survey intersect with closed areas. In 1 of them, the closed area represents less than 1% and in 7 more than the 30% of the total area, reaching the 50% in one stratum (Table 2). As the closed areas are all in the deeper depths, none of the shallower strata (less than 549 meters depth) are affected, except for two strata (513 and 514), which have only 0-ish% and 2% affected areas, respectively.

Table 4A shows the number of valid hauls by strata during 1988-2021 in the 3M survey. These are the hauls considered to calculate the indices in the base case. Between 1988 and 2003, only the shallower strata (less than 730 meters depth) were prospected. It can be observed that the minimum number of valid hauls by stratum is 2, except in the strata 517 in two years (1993 and 2011), in which only 1 haul was performed. And in 1993 there were two strata not surveyed, 514 and 518. Figure 2 presents the initial position of the hauls during the whole time series. It can be seen that there are some areas barely or never prospected as the bottom is not appropriate.

Tables 4B and 4C, as well as Figure 3 (left panel) present the number and the percentage of valid hauls in the closed areas during the period 1988-2021 in the 3M survey. In percentage, there are five strata with more of 30% of the hauls inside the closed areas, and only one with less than 10%. There are some strata in which all the hauls made in a particular year are in the closed areas, some cases in which the hauls are more than 65%, and many cases in which the hauls in closed areas are the 50% of the total. By year, the maximum percentage of hauls in close areas is 12.35%. This percentage could have more or less impact in the total results depending on the total number of hauls made and the distribution of the analyzed species. In Figure 4 the position of the valid hauls inside the closed areas is shown.

Table 4D presents the subtraction between Table 4A and Table 4B, so the number of hauls in the area that remains after removing the hauls in the closed areas. These are the hauls considered to calculate the indices in the new case. There are 5 cases with 0 hauls (in red in the table, there is no biomass in those cases), and 42 cases with 1 haul (in yellow in the table, the standard error can not be calculated).

Divisions 3NO survey

7 out of 39 strata surveyed during the Div. 3NO survey intersect with closed areas. In 3 of them, the closed area represents more than the 35% of the total area, reaching the 89% in stratum 755 (Table 2). As the closed areas are all in the deeper depths, none of the shallower strata (less than 549 meters depth) are affected.

Table 5A shows the number of valid hauls by strata during 1995-2021 in the 3NO survey. These are the hauls considered to calculate the indices in the base case. It can be observed that there are several cases with only 1 haul performed by strata, and with strata not surveyed. Figure 2 presents the position of the hauls during the whole time series. It can be seen that there are some areas barely or never prospected as the bottom is not appropriate.

Tables 5B and 5C, as well as Figure 3 (middle panel) present the number and the percentage of valid hauls in the closed areas during the period 1995-2021 in the 3NO survey. In percentage, the most affected strata are the 755 (95.8%) and the 759 (57.1%). The less affected are 753 (3%), 758 and 765 (4% each). In strata 755 and 759 all the hauls made in several years are in the closed areas. By year, the maximum percentage of hauls in close areas is 6.6%. This percentage could have more or less impact in the total results depending on the total number of hauls made and the distribution of the analyzed species. In Figure 4 the position of the valid hauls inside the closed areas is shown.

Table 5D presents the subtraction between Table 5A and Table 5B, so the number of hauls in the area that remains after removing the hauls in the closed areas. These are the hauls considered to calculate the indices in the new case. Stratum 755 remains without hauls except in years 2000 and 2005, when 1 haul remains. So, this stratum is almost totally absent in the calculation of the indices. In stratum 759 only 4 years have more than 1 haul. The cases in which only one valid haul remains, and so we have no way to calculate standard error, are 39 (in yellow in the table).

Division 3L survey

8 out of 24 strata surveyed during the Div. 3L survey intersect with closed areas. In 5 of them, the closed area represents more than the 37% of the total area, reaching the 78% in stratum 748 (Table 2). As the closed areas are all in the deeper depths, none of the shallower strata (less than 549 meters depth) are affected except strata 729 with 2% of the area.

Table 6A shows the number of valid hauls by strata during 2003-2019 in the 3L survey. These are the hauls considered to calculate the indices in the base case. It can be observed that from year 2006 the minimum number of valid hauls by stratum is 2, except in the strata 749 in 2007, where only 1 haul was performed. Figure 2 presents the position of the hauls during the whole time series.

Tables 6B and 6C, as well as Figure 3 (right panel) present the number and the percentage of valid hauls in the closed areas during the period 2003-2019 in the 3L survey. In percentage, there are four strata with more than 44.2% of the hauls inside the closed areas (reaching 91% in stratum 730), and two with less than 6.9%. By year, the maximum percentage of hauls in close areas is 14%. In Figure 4 the position of the valid hauls inside the closed areas is shown.

Table 6D presents the subtraction between Table 6A and Table 6B, so the number of hauls in the area that remains after removing the hauls in the closed areas. These are the hauls considered to calculate the indices in the new case. Stratum 748 and 749 have zero or one haul each year (except 749 in 2019, with 2 hauls). The cases in which only one valid haul remains, and so we have no way to calculate standard error, are 33 (in yellow in the table).

Indices of the species

Division 3M survey

Cod (stock in Division 3M)

Table 7a presents the biomass of the 3M cod during the EU 3M survey (1988-2021), and Table 7b the percentage of difference of that biomass when we remove the hauls in the closed areas from the calculation. No biomass is presented in the strata of more than 700m, so only the indices until 700 meters are presented in Figure 5. As expected, minor changes occur in the biomass of this species that prefers depths less than 600 m (Table 7b, Figure 5 top panel). There are some differences in 12 cases that does not affect the total biomass or SD. Bias is not significant for this stock (Figure 5 bottom left panel, Table 3), and the CV is the same in the base and in the new cases (Figure 5 bottom right panel).

Due to these results, no age distribution is shown. In any case, no major differences in the age distribution were encountered.

Greenland halibut (stock in Subarea 2 + Divisions 3KLMNO)

Indices for depths up to 700m and for depths up to 1400m are presented separately for this species, as its distribution is in the whole water column.

For the shallower strata (less than 700m, since 1988), differences of no more than 14% can be seen in the total biomass year by year except in 1992 with a 26% of difference (Table 8b, Figure 6a top panel). Except that year, the trends in biomass are quite similar, but in some strata in some years the differences are very high, up to 249%. The bias is in general negative in the first few years and positive afterwards, being significant (Figure 6a bottom left panel, Table 3). In general, the CV is quite similar between years although in some cases the difference is quite important (Figure 6a bottom right panel). So, it seems that removing the closed areas in these strata can affect the perception of the stock.

With regard the age distribution in the shallower strata, there are more differences in the very first years and since 2010, quite important in some cases (Table 9b, Figure 6b). Although the total number of individuals is not deeply affected except in a few years, the distribution by age change in some years. Note that the ALK for Greenland halibut in the 3M survey is only available since 1991.

For all the strata (less than 1400m, since 2004), the differences are very scarce and in general low, being overall the biomass higher in the new case (Table 8b, Figure 7a top panel). The bias shows a marked decreasing trend, being positive in the first years and negative afterwards, although the magnitude is much lower than in the case

of the shallower strata. The change in the bias is significant (Figure 7a bottom left panel, Table 3). A notably increase in the SD and the CV of the new series can be seen (Table 8b, Figure 7a bottom right panel). Noted that the y-axis of the bias Figures for less than 700m and for less than 1400m (Figures 6a and 7a) are different.

The age distribution for the whole depth range reflects the same impression as in the shallower strata, with the total abundance quite similar between both scenarios but some important changes in the number distribution by age (Table 10b, Figure 7b).

So, the indices of the Greenland halibut in the EU 3M survey seem to change if the hauls in the closed areas are removed. This is not unexpected as this species inhabits preferably the deeper strata. This could affect the results of the assessment of this stock, that is performed via an analytical assessment model.

American plaice (stock in Division 3M)

Table 11a presents the biomass of the 3M American plaice during the EU 3M survey (1988-2021), and Table 11b the percentage of difference of that biomass when we remove the hauls in the closed areas from the calculation. No biomass is presented in the strata of more than 700 meters, so only the indices until 700 meters are presented in Figure 8. As expected, minor changes occur in this species that prefers shallower depths (Table 11b, Figure 8 top panel). There are some differences in a few cases that does not affect the total biomass or SD. Bias is not significant for this stock (Figure 8 bottom left panel, Table 3), and the CV is the same in the base and in the new cases (Figure 8 bottom right panel).

Due to these results, no age distribution is shown. In any case, no differences in the age distribution were encountered.

Golden redfish (stock in Division 3M)

Table 12a presents the biomass of the 3M golden redfish during the EU 3M survey (1988-2021), and Table 12b the percentage of difference of that biomass when we remove the hauls in the closed areas from the calculation. No biomass is presented in the strata of more than 700 meters, so only the indices until 700 meters are presented in Figure 9. As expected, minor changes occur in this species that prefers shallower depths (Table 12b, Figure 9 top panel). There are some differences in a few cases that does not affect the total biomass or SD except in 1988. Bias is not significant for this stock (Figure 9 bottom left panel, Table 3), and the CV is the same in the base and in the new cases (Figure 9 bottom right panel).

Due to these results, no age distribution is shown. In any case, no differences in the age distribution were encountered.

Deepwater redfish (stock in Division 3M together with Acadian redfish as beaked redfish)

The deepwater redfish is assessed together with the Acadian redfish as beaked redfish due to the difficulties in separating both species. In the EU 3M survey these two species have been systematically identified since 1991, from when separated indices are available for both species.

Table 13a presents the biomass of the 3M deepwater redfish during the EU 3M survey (1991-2021), and Table 13b the percentage of difference of that biomass when we remove the hauls in the closed areas from the calculation. Little amount of biomass is presented in the strata of more than 700 meters, and although in some cases the differences are quite important, there are no differences in the results until 700 meters and until 1400 meters, so only the indices until 700 meters are presented in Figure 10.

There are a few important changes in the biomass of this stock when the hauls in the closed areas are removed, especially in strata 518. As in that stratum the catches of redfish are not too high, they do not affect too much the total biomass (Table 13b, Figure 10 top panel). The bias presents a clear decreasing trend and the change is significant (Figure 10 bottom left panel, Table 3). The CV is the virtually the same between both series (Figure 10 bottom right panel).

Despite the small differences in the biomass, some differences have been found in the age distribution of this stock, especially in 2013 (Table 14a, Figure 10b), although the total abundance is not affected (Table 14b). Note that no ALK is available before 1992 for this stock, and that due to technical problems with the database, no ALK was available for this study in some years.

So, although the biomass index of this stock is not deeply affected in the new case, the bias and the change in the age distribution could be a concern. This could affect the results of the assessment of this stock, that is performed via an analytical assessment model.

Acadian redfish (stock in Division 3M together with deepwater redfish as beaked redfish)

Table 15a presents the biomass of the 3M Acadian redfish during the EU 3M survey (1991-2021), and Table 15b the percentage of difference of that biomass when we remove the hauls in the closed areas from the calculation. Little amount of biomass is presented in the strata of more than 700 meters, so only the indices until 700 meters are presented in Figure 11.

There are a few changes in the biomass of this stock when the hauls in the closed areas are removed, some of them being quite important, although the total biomass is not affected (Table 15b, Figure 11 top panel). In fact, the bias is not important and not significant (Figure 11 bottom left panel, Table 3). The CV is the virtually the same between both series (Figure 11 bottom right panel).

Due to these results, no age distribution is shown. In any case, no differences in the age distribution were encountered in general.

Roughhead grenadier (stock in Subareas 2 and 3)

Indices for depths up to 700m and for depths up to 1400m are presented separately for this species, as its distribution is in the whole water column.

For the shallower strata (less than 700m, since 1988), differences up to more than 52% can be seen in the total biomass year by year (Table 16b, Figure 12a top panel). The bias is mostly negative and the fit is not significant (Figure 12a bottom left panel, Table 3). In general, the CV is lower in the base case in the first years and higher in the last years, and the differences are quite important in some years (Figure 12a bottom right panel). So, it seems that removing the closed areas in these strata can affect the perception of the stock.

With regard the age distribution in the shallower strata, there are differences in all years, quite important in some cases (Table 17b, Figure 12b). Both the distribution of the ages and the total abundance are quite different in some year. Note that the ALK for roughhead grenadier in the 3M survey is only available since 1994.

For all the strata (less than 1400m, since 2004), the differences are very important in some cases, being overall the biomass higher in the base case (Table 16b, Figure 13a top panel). The gam gives a quite stable bias although in general negative, and the fit is not significant (Figure 13a bottom left panel, Table 3). In general, there is an increase in the SD and the CV of the new series (Table 16b, Figure 13a bottom right panel). Noted that the y-axis of the bias Figures for less than 700m and for less than 1400m (Figures 12a and 13a) are different.

The age distribution for the whole depth range reflects some important changes in some of the ages, although in this case the different in the total abundance are less important than in the shallower case (Table 18b, Figure 13b).

So, the indices of the roughhead grenadier in the EU 3M survey seem to change if the hauls in the closed areas are removed. This is not unexpected as this species inhabits preferably the deeper strata. This could affect the results of the assessment of this stock, that is performed via an analytical assessment model when made.

Squid (stock in Subareas 3 and 4)

Table 19a presents the biomass of the 3M squid during the EU 3M survey (1988-2021), and Table 19b the percentage of difference of that biomass when we remove the hauls in the closed areas from the calculation. Little amount of biomass is presented in the strata of more than 700 meters, and although in some cases the differences are quite important, there are no differences in the results until 700 meters and until 1400 meters, so only the indices until 700 meters are presented in Figure 14. There are some important differences in the biomass by strata in some years, but the total biomass is in general not affected (Table 19b, Figure 14 top panel). Bias is not significant for this stock (Figure 14 bottom left panel, Table 3), and the CV is the same in almost all the years (Figure 14 bottom right panel).

Some differences were encountered in the lengths of this stock between the base and the new case, so the length distribution is presented. Please note that no ALK is available for this species in this survey, so age distribution is not available. It is remarkable the difference in the numbers at lengths between 3 cm and 17 cm between 1996 and 2008, although it that does not affect significantly the total abundance as they are not the most abundant lengths (Table 20b, Figure 15).

So, although the biomass index of this stock is not deeply affected in the new case, the change in the length distribution could be a concern. This is something to consider if sometime the length distribution is used in the assessments of this stock and the hauls in the closed areas are removed.

Division 3NO survey

Cod (stock in Divisions 3NO)

Table 21a presents the biomass of the 3NO cod during the Spain-3NO survey (1995-2021), and Table 21b the percentage of difference of that biomass when we remove the hauls in the closed areas from the calculation. As expected, no changes occur in the biomass of this species that prefers depths less than 600 m (Table 21b, Figure 16 top panel). It does not exist bias for this stock (Figure 16 bottom left panel, Table 3), and the CV is the same in the base and in the new cases (Figure 16 bottom right panel).

Due to these results, no age distribution is shown. In any case, no differences in the age distribution were encountered.

Greenland halibut (stock in Subarea 2 + Divisions 3KLMNO)

Differences up to 33% in the total biomass can be seen in the total biomass year by year (Table 22b, Figure 17 top panel). Biomass in strata 755 almost disappears in the new case. The bias is negative in almost all years and the change is significant (Figure 17 bottom left panel, Table 3). The SD is always higher and the CV in general too in the new case (Figure 17 bottom right panel). So, it seems that removing the closed areas in these strata can affect the perception of the stock.

With regard the age distribution, differences can be seen along all the years, being more important since 2008 and in general lower in the new case (Table 23b, Figure 18). The distribution by age are affected in many years, although the total number of individuals is quite similar.

So, the indices of the Greenland halibut in the EU-Spain 3NO survey seem to change if the hauls in the closed areas are removed. This is not unexpected as this species inhabits preferably the deeper strata. This could affect the results of the assessment of this stock, that is performed via an analytical assessment model.

American plaice (stock in Divisions 3LNO)

Table 24a presents the biomass of the 3NO American plaice during the Spain-EU 3NO survey (1995-2021), and Table 24b the percentage of difference of that biomass when we remove the hauls in the closed areas from the calculation. As expected, minor changes occur in this species that prefers shallower depths (Table 24b, Figure 19 top panel). There are some differences in some cases that does not affect the total biomass or SD. Bias is no

significant for this stock (Figure 19 bottom left panel, Table 3). The CV is the same in the base and in the new cases (Figure 19 bottom right panel).

Due to these results, no age distribution is shown. In any case, no differences in the age distribution were encountered.

Redfish (stocks in Divisions 3LN and 3O)

The three redfish species (golden redfish, deepwater redfish and Acadian redfish) are not separated during the EU-Spain 3NO survey, so global indices for all of them are presented.

Table 25a presents the biomass of the 3NO redfish during the Spain-EU 3NO survey (1995-2021), and Table 25b the percentage of difference of that biomass when we remove the hauls in the closed areas from the calculation. Minor changes occur in this species that prefers shallower depths (Table 25b, Figure 20 top panel). There are some differences in a few cases, that does not affect the total biomass or SD. Bias is no significant for this stock (Figure 20 bottom left panel, Table 3). The CV is the same in the base and in the new cases (Figure 20 bottom right panel).

Due to these results, no length distribution is shown. In any case, no major differences in the length distribution were encountered. No ALK is available for this species in this survey.

Roughhead grenadier (stock in Subareas 2 and 3)

Differences up to 40% are found for roughhead grenadier in the total biomass year by year (Table 26b, Figure 12a top panel). The bias is negative in all years except 2 and the change is significant (Figure 21 bottom left panel, Table 3). In general, the SD is higher and the CV lower in the base case and the differences are quite important in some years (Figure 21 bottom right panel). So, it seems that removing the closed areas in these strata can affect the perception of the stock.

For roughhead grenadier ALK is not available for this survey, so length distribution is presented. The differences are quite important all the years of the series presented, both for the distribution by age as for the total abundance, having in general a smaller number of individuals in the new case (Table 27b, Figure 22).

So, the indices of the roughhead grenadier in the Spain-EU 3NO survey seem to change if the hauls in the closed areas are removed. This is not unexpected as this species inhabits preferably the deeper strata. This could affect the results of the assessment of this stock, that is performed via an analytical assessment model when made.

Witch flounder (stock in Divisions 3NO)

Table 28a presents the biomass of the 3NO witch flounder during the Spain-EU 3NO survey (1995-2021), and Table 28b the percentage of difference of that biomass when we remove the hauls in the closed areas from the calculation. Minor changes occur in the total biomass of this species (Table 28b, Figure 23 top panel). There are some differences in a few cases, some of them quite significant, but do not affect the total biomass or SD. Bias is not significant for this stock (Figure 23 bottom left panel, Table 3), and the CV is the same in the base and in the new cases (Figure 23 bottom right panel).

Despite the results in biomass found, some differences were encountered in the lengths of this stock between the base and the new case, so the length distribution is presented. It is remarkable the difference in the numbers at lengths between 8 cm and 35 cm in 2017 and 2018, although it that does not affect the total abundance as they are not the most abundant lengths (Table 29b, Figure 24). This is something to consider if sometime the length distribution is used in the assessment of this stock and the hauls in the closed areas are removed. No ALK is available for this species in this survey.

So, although the biomass index of this stock is not deeply affected in the new case, the change in the length distribution could be a concern. Currently a production model is used for this stock, but length distribution is used to derive a recruitment index, especially the more affected lengths (lengths < 21 cm).

Yellowtail flounder (stock in Divisions 3LNO)

Table 30a presents the biomass of the 3NO yellowtail plaice during the Spain-EU 3NO survey (1995-2021), and Table 30b the percentage of difference of that biomass when we remove the hauls in the closed areas from the calculation. As expected, no changes occur in this species that prefers shallower depths (Table 29b, Figure 25 top panel). Bias does not exist for this stock (Figure 25 bottom left panel, Table 3), and the CV is the same in the base and in the new cases (Figure 25 bottom right panel).

Due to these results, no length distribution is shown. In any case, no differences in the length distribution were encountered. No ALK is available for this species in this survey.

Capelin (stock in Divisions 3LNO)

Table 31a presents the biomass of the 3NO capelin during the Spain-EU 3NO survey (1995-2021), and Table 31b the percentage of difference of that biomass when we remove the hauls in the closed areas from the calculation. As expected, minor changes occur in this species that prefers shallower depths (Table 31b, Figure 26 top panel). Bias has a slightly increase trend but it is due to only two small point, being the rest of the ratios very close or equal to 1, and it is not significant (Figure 26 bottom left panel, Table 3), and the CV is the same in the base and in the new cases (Figure 26 bottom right panel).

Due to these results, no length distribution is shown. In any case, no differences in the length distribution were encountered. No ALK is available for this species in this survey.

Thorny skate (stock in Divisions 3LNO and Subdivision 3Ps)

Table 32a presents the biomass of the 3NO thorny skate during the Spain-EU 3NO survey (1995-2021), and Table 32b the percentage of difference of that biomass when we remove the hauls in the closed areas from the calculation. Minor changes occur in this species except in 1998 and 2002, when an increase in the biomass and a decrease in the SD occurs in the new case (Table 32b, Figure 27 top panel). In the rest of the years, total biomass is not affected for removing the hauls in the closed areas. Bias is not significant for this species in this survey, although a slight decreasing trend is presented. (Figure 27 bottom left panel, Table 3). The CV is the same in the base and in the new cases except in 2018 and 2022 (Figure 27 bottom right panel).

Due to the difference in biomass in years 1998 and 2002, some differences can be seen in the length distribution of this species. In general, the numbers at length in those years are higher in the new case, although in 1998 we “loose” some lengths. Note that there are some differences in 1997, too, to lower numbers (Table 33b, Figure 28). This is something to consider if sometime the length distribution is used in the assessment of this stock and the hauls in the closed areas are removed. No ALK is available for this species in this survey.

So, although the changes are no deep in the new case, they are something to be considered in this stock. Currently no analytical or production assessment model is applied to this stock, and the 3NO survey indices are not considered in the state of the stock, but if this change in the future these changes must be taken into account.

White hake (stock in Divisions 3NO and Subdivision 3Ps)

Table 34a presents the biomass of the 3NO white hake during the Spain-EU 3NO survey (1995-2021), and Table 34b the percentage of difference of that biomass when we remove the hauls in the closed areas from the calculation. No changes occur in this species except in 2019, but in a very small amount of biomass (Table 34b, Figure 29 top panel). Bias is not significant for this species in this survey, (Figure 29 bottom left panel, Table 3). The CV is the same in the base and in the new cases (Figure 29 bottom right panel).

Due to these results, no length distribution is shown. In any case, no differences in the length distribution were encountered (except length group 6 in 2019). No ALK is available for this species in this survey.

Squid (stock in Subareas 3 and 4)

Table 35a presents the biomass of the 3NO squid during the Spain-EU 3NO survey (1995-2021), and Table 35b the percentage of difference of that biomass when we remove the hauls in the closed areas from the calculation. There are some differences in the biomass by strata in some years, but the total biomass is not affected except in year 2012 (Table 35b, Figure 30 top panel). Bias is not significant for this stock, but all the ratios are under or equal to 1 and an increasing trend is displayed (Figure 30 bottom left panel, Table 3). The CV is the same in almost all the years (Figure 30 bottom right panel).

Due to these results, no length distribution is shown. In any case, no differences in the length distribution were encountered. No ALK is available for this species in this survey.

Division 3L survey

Cod (stock in Divisions 2|3KL)

This stock is not assessed by NAFO but by DFO, although the results are presented regularly to the Scientific Council of NAFO, as well as the results of this survey for this species.

Table 36a presents the biomass of the 3L cod during the Spain-3NO survey (2003-2019), and Table 36b the percentage of difference of that biomass when we remove the hauls in the closed areas from the calculation. As expected, no changes occur in the biomass of this species that prefers depths less than 600 m (Table 36b, Figure 31 top panel). It does not exist bias for this stock (Figure 31 bottom left panel, Table 3), and the CV is the same in the base and in the new cases (Figure 31 bottom right panel).

Due to these results, no age distribution is shown. In any case, no differences in the age distribution were encountered.

Greenland halibut (stock in Subarea 2 + Divisions 3KLMNO)

Differences up to 369% in the biomass by strata can be seen, although in the total biomass the difference is never more than 7% and it is in general higher in the new case. In strata 730, the biomass almost disappears in the new case (Table 37b, Figure 32 top panel). The bias is positive in most of the years, but it is not significant (Figure 32 bottom left panel, Table 3). There are quite important differences both in the SD and in the CV (Figure 32 bottom right panel). SD seems to be more variable between years in the new base case. So, it seems that removing the closed areas in these strata can affect the perception of the stock.

With regard the length distribution, differences can be seen along all the years (Table 38b, Figure 33), but total number of individuals by year are not affected significantly (more than 10% of differences).

So, the indices of the Greenland halibut in the EU-Spain 3L survey seem to change if the hauls in the closed areas are removed. This is not unexpected as this species inhabits preferably the deeper strata. This could affect the results of the assessment of this stock, that is performed via an analytical assessment model.

American plaice (stock in Divisions 3LNO)

Table 39a presents the biomass of the 3L American plaice during the Spain-EU 3L survey (2003-2019), and Table 39b the percentage of difference of that biomass when we remove the hauls in the closed areas from the calculation. As expected, minor changes occur in this species that prefers shallower depths (Table 39b, Figure 34 top panel). The major differences are encountered in 2003, due to strata 730 biomass. Bias is significant for this stock due to the 2003 ratio, but the rest of the years the ratios are very close to 1, so it seems not to be

dangerous (Figure 34 bottom left panel, Table 3). The CV is the same in the base and in the new cases except in 2003 (Figure 34 bottom right panel).

Due to these results, no length distribution is shown. Some differences are encountered in 2003, but as the indices of these year are not used in the assessment, they seem not to be dangerous.

Redfish (stocks in Divisions 3LN and 3O)

As in the EU-Spain 3NO survey, the three redfish species (golden redfish, deepwater redfish and Acadian redfish) are not separated during the EU-Spain 3L survey, so global indices for all of them are presented.

Table 40a presents the biomass of the 3L redfish during the Spain-EU 3L survey (2003-2019), and Table 40b the percentage of difference of that biomass when we remove the hauls in the closed areas from the calculation. Some important changes occur in some strata, mainly in the 730, in which the biomass of this species almost disappears, although the total biomass by year is rarely affected (Table 40b, Figure 35 top panel). Bias is not significant for this stock, but all the values are negative and the trend is a positive trend can be seen (Figure 35 bottom left panel, Table 3). The CV is very close in both cases (Figure 35 bottom right panel).

Some differences were encountered in the lengths of this stock between the base and the new case, so the length distribution is presented. It is remarkable the difference in the numbers at lengths between 28 cm and 43 cm, although it that does not affect the total abundance as they are not the most abundant lengths (Table 41b, Figure 36). This is something to consider if sometime the length distribution is used in the assessment of this stock and the hauls in the closed areas are removed. No ALK is available for this species in this survey.

So, although the biomass index of this stock is not deeply affected in the new case, the change in the length distribution could be a concern. Currently a production model is used for this stock, but length distribution is used to derive a recruitment index and a female spawning stock biomass.

Roughhead grenadier (stock in Subareas 2 and 3)

Very important differences can be seen in the roughhead grenadier biomass by strata, and differences up to 44% are found for in the total biomass year by year, being always higher in the base case except for 2004 (Table 42b, Figure 37 top panel). The bias is always negative but 2004 and although it is not significant, it presents a clear decreasing trend (Figure 37 bottom left panel, Table 3). In general, the SD is higher and the CV lower in the base case and the differences are quite important in some years (Figure 37 bottom right panel). So, it seems that removing the closed areas in these strata can affect the perception of the stock.

For roughhead grenadier ALK is not available for this survey, so length distribution is presented. The differences are quite important all the years of the series presented, both for the distribution by age as for the total abundance, that is always lower in the new case (Table 43b, Figure 38).

So, the indices of the roughhead grenadier in the Spain-EU 3L survey seem to change dramatically if the hauls in the closed areas are removed. This is not unexpected as this species inhabits preferably the deeper strata. This could affect the results of the assessment of this stock, that is performed via an analytical assessment model when made.

Witch flounder (stock in Divisions 2J3KL)

Table 44a presents the biomass of the 3L witch flounder during the Spain-EU 3L survey (2003-2019), and Table 44b the percentage of difference of that biomass when we remove the hauls in the closed areas from the calculation. Minor changes occur in the total biomass of this species (Table 44b, Figure 39 top panel). There are some differences in some cases, some of them quite significant, but do not affect the total biomass except in 2003. The SD has some differences in some years. It is remarkable that the biomass in stratum 730 is quite different several years. Bias is significant for this stock due to the 2003 ratio, but the rest of the years the

ratios are close to 1, so it seems not to be dangerous (Figure 39 bottom left panel, Table 3). The CV is in general quite similar in the base and in the new cases (Figure 39 bottom right panel).

Length distribution is presented for this stock despite the results found in biomass, as some differences were encountered in the lengths of this stock between the base and the new case, although they do not affect the total abundance except in year 2003 (Table 45b, Figure 40). But this is something to consider if sometime the length distribution is used in the assessment of this stock and the hauls in the closed areas are removed. No ALK is available for this species in this survey.

The changes in length distribution could be a concern in the future.

Thorny skate (stock in Divisions 3LNO and Subdivision 3Ps)

Table 46a presents the biomass of the 3L thorny skate during the Spain-EU 3L survey (2003-2019), and Table 46b the percentage of difference of that biomass when we remove the hauls in the closed areas from the calculation. Minor changes occur in this species in the total biomass except in 2003, although in some strata the difference is quite high but they are over small amount of biomass (Table 46b, Figure 41 top panel). Bias is significant for this stock due to the 2003 ratio, but the rest of the years the ratios are close to 1, so it seems not to be dangerous (Figure 41 bottom left panel, Table 3). The CV is almost the same in the base and in the new cases (Figure 41 bottom right panel).

Due to these results, no length distribution is shown. In any case, no great differences in the length distribution were encountered (except for 2003). No ALK is available for this species in this survey.

Discussion

The three EU surveys conducted by Spain and Portugal are analysed in the present document to study the impact in the survey indices of removing the hauls in the closed areas in the historic series. Since 2018 hauls in the closed areas have been tried to be omitted in the design of the survey. For that, in the previous study done (González-Troncoso *et al.*, 2021), most differences came from the previous years. But the addition of new closed areas in September 2021 by the Commission extended the differences in this study to all the years.

Most of the closed areas are in deeper waters, so the species that inhabit the shallower strata are barely or nothing affected by removing the hauls in the closed areas.

Eight species survey indices were analysed in the 3M survey. From them, six have no major changes in the survey index biomass. The other two, Greenland halibut and roughhead grenadier, are known to live mainly in the deeper waters, so it is not surprising that their indices are affected by removing the hauls in the closed areas. In the case of these two species, both biomass and age structure are affected by the removal, which can lead the assessment to give different results if the hauls in the closed areas are removed.

Moreover, two species, deepwater redfish and squid, whose biomass are barely affected, have changed their age/length distributions in the new case. In the case of the redfish, an XSA is used to perform the assessment (of the beaked redfish), so changes in the age distribution could lead to changes in assessment results. In the case of the squid, currently the length distribution is not used in the assessment.

Eleven species survey indices were analysed in the 3NO survey, carried out since 1995. From them, nine survey indices have no major changes in the biomass. The other two indices, the same as in the 3M survey, Greenland halibut and roughhead grenadier are affected by removing the hauls in the closed areas. In the case of these two species, both biomass and age structure are affected by the removal, which can lead the assessment to give different results if the hauls in the closed areas are removing.

Moreover, two species, witch flounder and thorny skate, whose biomasses are barely affected, have changed its length distribution in the new case. In the case of witch flounder, a production model is performed to assess the stock, but the length distribution is used to derive a recruitment index of the survey. In the case of the

thorny skate no analytical or production model is performed, and only the Canadian survey indices are taken for the state of the stock, but if the future the assessment model changes this could be a matter of concern.

Seven species survey indices were analysed in the 3L survey, carried out since 2003. From them, five have no major changes in the biomass. The other two, Greenland halibut and roughhead grenadier are affected by removing the hauls in the closed areas. In the case of these two species, both biomass and age structure are affected by the removal, which can lead the assessment to give different results if the hauls in the closed areas are removing.

Furthermore, two species, redfish and witch flounder, whose biomass are barely affected, have changed their length distributions in the new case. In the case of the redfish, although a production model is performed to assess the stock, the length distribution is used to derive recruitment index and female stock spawning biomass indices of the survey.

In summary, there are two species, Greenland halibut and roughhead grenadier, in which their biomass and/or age/length indices are affected in all the surveys analyzed. This is due to the fact that these two species are distributed at greater depths and that the closed areas are mainly found in deep areas, so the suppression of survey hauls in closed areas has a greater impact on the indices of these two species. The best way to know the impact in the assessment results of these changes in the Greenland halibut and roughhead grenadier indices would be to run the assessment with both indices, the base case ones and the new case ones, and compare the results.

Changes in the trend in the bias of the biomass in some species could be a matter of concern too. Although the biomass does not change noticeably, change in the bias of the indices could lead to changes in the results of the assessment models.

There are other species in which their global biomass indices do not change very much, but their age or length indices change appreciably when hauls from closed areas are removed from the calculations. In one case, the results of the assessment are compromised and it would be better to rerun the assessment with the new case indices to see the differences. In other cases, although the length distribution is not directly used in the assessment models, some recruitment and spawning stock biomass indices are derived from them, so changes in the perception of the stock could be encountered. These changes in the age/length indices should be considered in future assessments of these stocks if the prohibition of the surveys trawls in closed areas is approved.

The NAFO Commission established coral and sponges protection closures areas to bottom fisheries within the NAFO Regulatory Area that started to be applied in 2010 after an assessment made by the Scientific Council. Currently, 18 area closures are in force in the NRA after a reassessment of the closures that lead to new closures during the 2021 NAFO Annual meeting. For that, this study has to be rewritten to fit the new closures since then submitted to NAFO in September 2021. The addition of the new close areas does not change substantially the view of most of the species, but for the species with differences now they are more noticeable. If more close areas are added in the future to the existing ones, this study should be redone, which implies a big amount of work. It is not worth to rerun this study each time the closed areas change.

Acknowledges

The authors would like to thank to all the people that make possible this type of works: onboard observers in survey vessels who obtain the data, and lab people who process them.

This work has been funded by European Union NextGenerationEU. The surveys have been co-funded by the EU through the European Maritime, Fisheries and Aquaculture Fund (EMFAF) within the Spain Work Plan for data collection in the fisheries and aquaculture sectors regarding the Common Fisheries Policy.

Table 3. Species and stocks studied in the present document. If age or length distribution is presented is pointed out in the table. The p-value of the gam of the bias (until 700 m and until 1400 m) is presented, and the significant fits (<0.05) are highlighted in red. The maximum difference in percentage of the biomass is presented; if it is positive, the maximum is in the new case; if it is negative, the maximum is in the base case.

Table 4. Number of valid hauls by strata during the 3M survey (1988-2021). n.s. means stratum not surveyed. The strata with closed areas are marked in red. In blue, the cases with just 1 valid haul made during the normal operations of the survey. In red, the cases with 0 valid hauls after removing the hauls in the closed areas. In yellow, the cases with 1 valid haul after removing the hauls in the closed areas. A: Number of valid hauls. B: Number of valid hauls inside the closed areas. C: Percentage of hauls inside the closed areas. D: Number of hauls left after removing the hauls in the closed areas.

Table 5. Number of valid hauls by strata during the 3NO survey (1995-2021). n.s. means stratum not surveyed. The strata with closed areas are marked in red. In blue, the cases with just 1 valid haul made during the normal operations of the survey. In red, the cases with 0 valid hauls after removing the hauls in the closed areas. In yellow, the cases with 1 valid haul after removing the hauls in the closed areas. A: Number of valid hauls. B: Number of valid hauls inside the closed areas. C: Percentage of hauls inside the closed areas. D: Number of hauls left after removing the hauls in the closed areas.

Table 6. Number of valid hauls by strata during the 3L survey (2003-2019). n.s. means stratum not surveyed. The strata with closed areas are marked in red. In blue, the cases with just 1 valid haul made during the normal operations of the survey. In red, the cases with 0 valid hauls after removing the hauls in the closed areas. In yellow, the cases with 1 valid haul after removing the hauls in the closed areas. A: Number of valid hauls. B: Number of valid hauls inside the closed areas. C: Percentage of hauls inside the closed areas. D: Number of hauls left after removing the hauls in the closed areas.

Table 7b. Difference in percentage between the Atlantic cod biomass by strata with and without the hauls in the closed areas, as total biomass and SD by year, in the EU 3M survey during years 1988-2021. In red, the cases with a difference of more than 10% when biomass in the base case is higher than the one in the new case. In orange, the cases with a difference of more than 10% when biomass in the base case is lower than the one in the new case.

Table 8b. Difference in percentage between the Greenland halibut biomass by strata with and without the hauls in the closed areas, as total biomass and SD by year, in the EU 3M survey during years 1988-2021. In red, the cases with a difference of more than 10% when biomass in the base case is higher than the one in the new case. In orange, the cases with a difference of more than 10% when biomass in the base case is lower than the one in the new case.

Table 9b. Difference in percentage between the Greenland halibut age distribution with and without the hauls in the closed areas in the EU 3M survey during years 1988-2021 until 700 m. In red, the cases with a difference of more than 10% when the base case is higher than the new case. In orange, the cases with a difference of more than 10% when the base case is lower than the new case. Before 1991, the ALK is not available.

Table 11b. Difference in percentage between the American plaice biomass by strata with and without the hauls in the closed areas, as total biomass and SD by year, in the EU 3M survey during years 1988-2021. In red, the cases with a difference of more than 10% when biomass in the base case is higher than the one in the new case. In orange, the cases with a difference of more than 10% when biomass in the base case is lower than the one in the new case.

Table 12b. Difference in percentage between the golden redfish biomass by strata with and without the hauls in the closed areas, as total biomass and SD by year, in the EU 3M survey during years 1988-2021. In red, the cases with a difference of more than 10% when biomass in the base case is higher than the one in the new case. In orange, the cases with a difference of more than 10% when biomass in the base case is lower than the one in the new case.

Table 13b. Difference in percentage between the deepwater redfish biomass by strata with and without the hauls in the closed areas, as total biomass and SD by year, in the EU 3M survey during years 1991-2021. In red, the cases with a difference of more than 10% when biomass in the base case is higher than the one in the new case. In orange, the cases with a difference of more than 10% when biomass in the base case is lower than the one in the new case.

Stratum	1991	1992	1993	1994	1995	1996	1997	1998	1999	2000	2001	2002	2003	2004	2005	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019	2020	2021

Table 14b. Difference in percentage between the deepwater redfish age distribution with and without the hauls in the closed areas in the EU 3M survey during years 1992-2021 until 700 m. In red, the cases with a difference of more than 10% when the base case is higher than the new case. In orange, the cases with a difference of more than 10% when the base case is lower than the new case. Before 1992, the ALK is not available. In 2004, 2010 and 2019 there were no ALK available for this study.

Table 15b. Difference in percentage between the Acadian redfish biomass by strata with and without the hauls in the closed areas, as total biomass and SD by year, in the EU 3M survey during years 1991-2021. In red, the cases with a difference of more than 10% when biomass in the base case is higher than the one in the new case. In orange, the cases with a difference of more than 10% when biomass in the base case is lower than the one in the new case.

Table 16b. Difference in percentage between the roughhead grenadier biomass by strata with and without the hauls in the closed areas, as total biomass and SD by year, in the EU 3M survey during years 1988-2021. In red, the cases with a difference of more than 10% when biomass in the base case is higher than the one in the new case. In orange, the cases with a difference of more than 10% when biomass in the base case is lower than the one in the new case.

Table 17b. Difference in percentage between the roughhead grenadier age distribution with and without the hauls in the closed areas in the EU 3M survey during years 1994-2021 until 700 m. In red, the cases with a difference of more than 10% when the base case is higher than the new case. In orange, the cases with a difference of more than 10% when the base case is lower than the new case.

Table 18b. Difference in percentage between the roughhead grenadier age distribution with and without the hauls in the closed areas in the EU 3M survey during years 2004-2021 until 1400 m. In red, the cases with a difference of more than 10% when the base case is higher than the new case. In orange, the cases with a difference of more than 10% when the base case is lower than the new case.

Table 20b. Difference in percentage between the squid age distribution with and without the hauls in the closed areas in the EU 3M survey during years 2004-2021 until 1400 m. In red, the cases with a difference of more than 10% when the base case is higher than the new case. In orange, the cases with a difference of more than 10% when the base case is lower than the new case.

Table 21b. Difference in percentage between the Atlantic cod biomass by strata with and without the hauls in the closed areas, as total biomass and SD by year, in the EU-Spain 3NO survey during years 1995-2021. In red, the cases with a difference of more than 10% when biomass in the base case is higher than the one in the new case. In orange, the cases with a difference of more than 10% when biomass in the base case is lower than the one in the new case.

Table 22b. Difference in percentage between the Greenland halibut biomass by strata with and without the hauls in the closed areas, as total biomass and SD by year, in the EU-Spain 3NO survey during years 1995-2021. In red, the cases with a difference of more than 10% when biomass in the base case is higher than the one in the new case. In orange, the cases with a difference of more than 10% when biomass in the base case is lower than the one in the new case.

Table 23b. Difference in percentage between the Greenland halibut age distribution with and without the hauls in the closed areas in the EU-Spain 3NO survey during years 1995-2021. In red, the cases with a difference of more than 10% when the base case is higher than the new case. In orange, the cases with a difference of more than 10% when the base case is lower than the new case.

Table 24b. Difference in percentage between the American plaice biomass by strata with and without the hauls in the closed areas, as total biomass and SD by year, in the EU-Spain 3NO survey during years 1995-2021. In red, the cases with a difference of more than 10% when biomass in the base case is higher than the one in the new case. In orange, the cases with a difference of more than 10% when biomass in the base case is lower than the one in the new case.

Table 25b. Difference in percentage between the redfish biomass by strata with and without the hauls in the closed areas, as total biomass and SD by year, in the EU-Spain 3NO survey during years 1995-2021. In red, the cases with a difference of more than 10% when biomass in the base case is higher than the one in the new case. In orange, the cases with a difference of more than 10% when biomass in the base case is lower than the one in the new case.

Table 26b. Difference in percentage between the roughhead grenadier biomass by strata with and without the hauls in the closed areas, as total biomass and SD by year, in the EU-Spain 3NO survey during years 1995-2021. In red, the cases with a difference of more than 10% when biomass in the base case is higher than the one in the new case. In orange, the cases with a difference of more than 10% when biomass in the base case is lower than the one in the new case.

Table 28b. Difference in percentage between the witch flounder biomass by strata with and without the hauls in the closed areas, as total biomass and SD by year, in the EU-Spain 3NO survey during years 1995-2021. In red, the cases with a difference of more than 10% when biomass in the base case is higher than the one in the new case. In orange, the cases with a difference of more than 10% when biomass in the base case is lower than the one in the new case.

Table 29b. Difference in percentage between the witch flounder length distribution with and without the hauls in the closed areas in the EU-Spain 3NO survey during years 1995-2021. In red, the cases with a difference of more than 10% when the base case is higher than the new case. In orange, the cases with a difference of more than 10% when the base case is lower than the new case.

Table 30b. Difference in percentage between the yellowtail flounder biomass by strata with and without the hauls in the closed areas, as total biomass and SD by year, in the EU-Spain 3NO survey during years 1995-2021. In red, the cases with a difference of more than 10% when biomass in the base case is higher than the one in the new case. In orange, the cases with a difference of more than 10% when biomass in the base case is lower than the one in the new case.

Table 31b. Difference in percentage between the capelin biomass by strata with and without the hauls in the closed areas, as total biomass and SD by year, in the EU-Spain 3NO survey during years 1995-2021. In red, the cases with a difference of more than 10% when biomass in the base case is higher than the one in the new case. In orange, the cases with a difference of more than 10% when biomass in the base case is lower than the one in the new case.

Table 32b. Difference in percentage between the thorny skate biomass by strata with and without the hauls in the closed areas, as total biomass and SD by year, in the EU-Spain 3NO survey during years 1995-2021. In red, the cases with a difference of more than 10% when biomass in the base case is higher than the one in the new case. In orange, the cases with a difference of more than 10% when biomass in the base case is lower than the one in the new case.

Table 33b. Difference in percentage between the thorny skate length distribution with and without the hauls in the closed areas in the EU-Spain 3NO survey during years 1995-2021. In red, the cases with a difference of more than 10% when the base case is higher than the new case. In orange, the cases with a difference of more than 10% when the base case is lower than the new case.

Table 34b. Difference in percentage between the white hake biomass by strata with and without the hauls in the closed areas, as total biomass and SD by year, in the EU-Spain 3NO survey during years 1995-2021. In red, the cases with a difference of more than 10% when biomass in the base case is higher than the one in the new case. In orange, the cases with a difference of more than 10% when biomass in the base case is lower than the one in the new case.

Table 35b. Difference in percentage between the squid biomass by strata with and without the hauls in the closed areas, as total biomass and SD by year, in the EU-Spain 3NO survey during years 1995-2021. In red, the cases with a difference of more than 10% when biomass in the base case is higher than the one in the new case. In orange, the cases with a difference of more than 10% when biomass in the base case is lower than the one in the new case.

Table 40b. Difference in percentage between the redfish biomass by strata with and without the hauls in the closed areas, as total biomass and SD by year, in the EU-Spain 3L survey during years 2003-2019. In red, the cases with a difference of more than 10% when biomass in the base case is higher than the one in the new case. In orange, the cases with a difference of more than 10% when biomass in the base case is lower than the one in the new case.

Table 42b. Difference in percentage between the roughhead grenadier biomass by strata with and without the hauls in the closed areas, as total biomass and SD by year, in the EU-Spain 3L survey during years 2003-2019. In red, the cases with a difference of more than 10% when biomass in the base case is higher than the one in the new case. In orange, the cases with a difference of more than 10% when biomass in the base case is lower than the one in the new case.

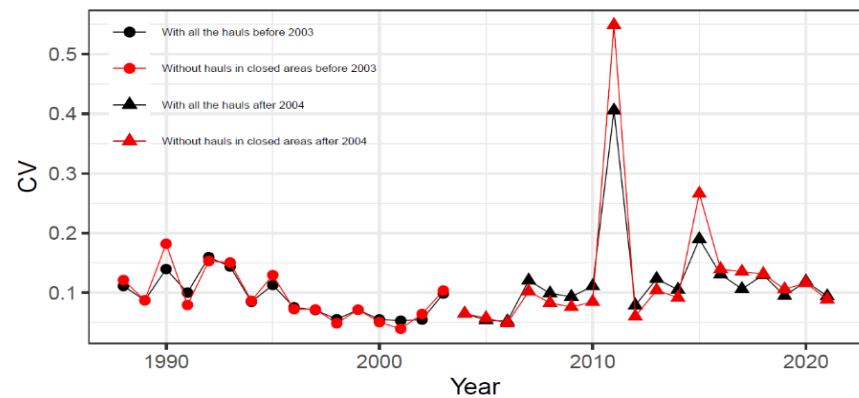

Figure 6a. Biomass and SD by year (1988-2021) of the Greenland halibut in 3M until 700 meters with and without the closed areas. Top plot: total biomass by year. Bottom left plot: log-ratio plot (indicating the relative bias caused by removing data from the protected areas and the GAM smoother trend line and 95% confidence intervals). Bottom right plot: CV of the biomass (SD/biomass).

Figure 6b. Age distribution by year (1991-2021) of the Greenland halibut in 3M until 700 meters with and without the closed areas.

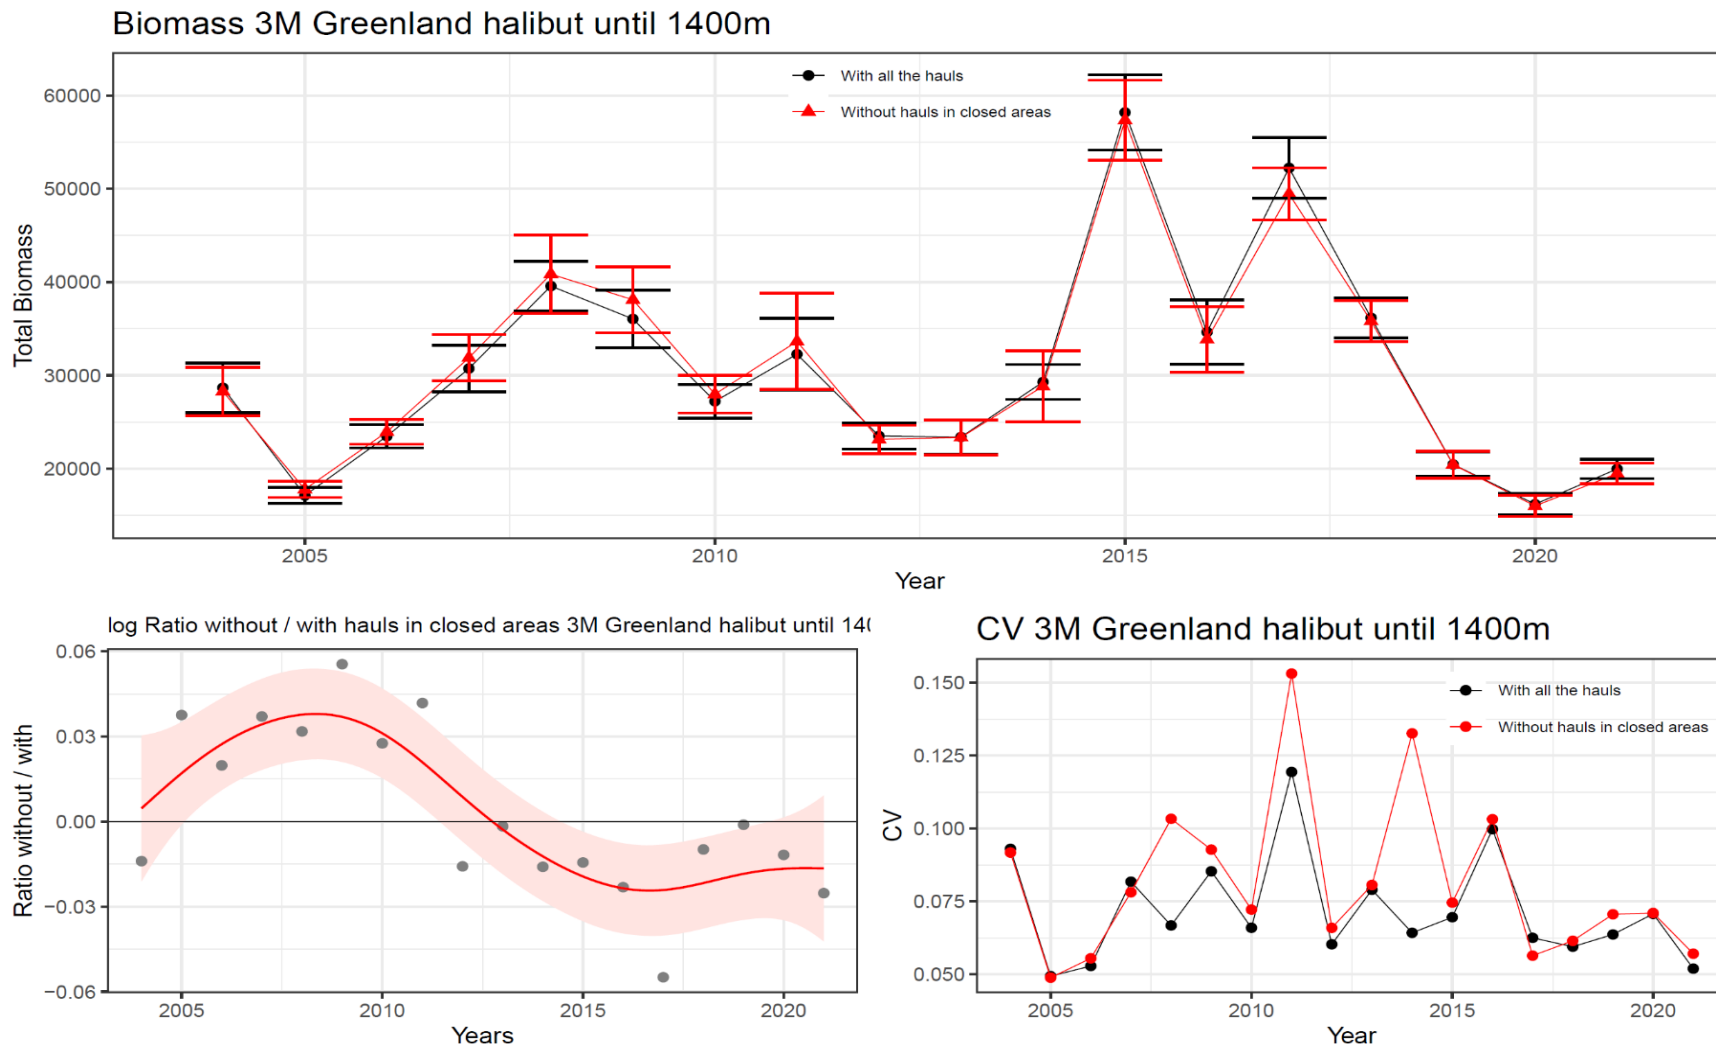

Figure 7a. Biomass and SD by year (1988-2021) of the Greenland halibut in 3M until 1400 meters with and without the closed areas. Top plot: total biomass by year. Bottom left plot: log-ratio plot (indicating the relative bias caused by removing data from the protected areas and the GAM smoother trend line and 95% confidence intervals). Bottom right plot: CV of the biomass (SD/biomass).

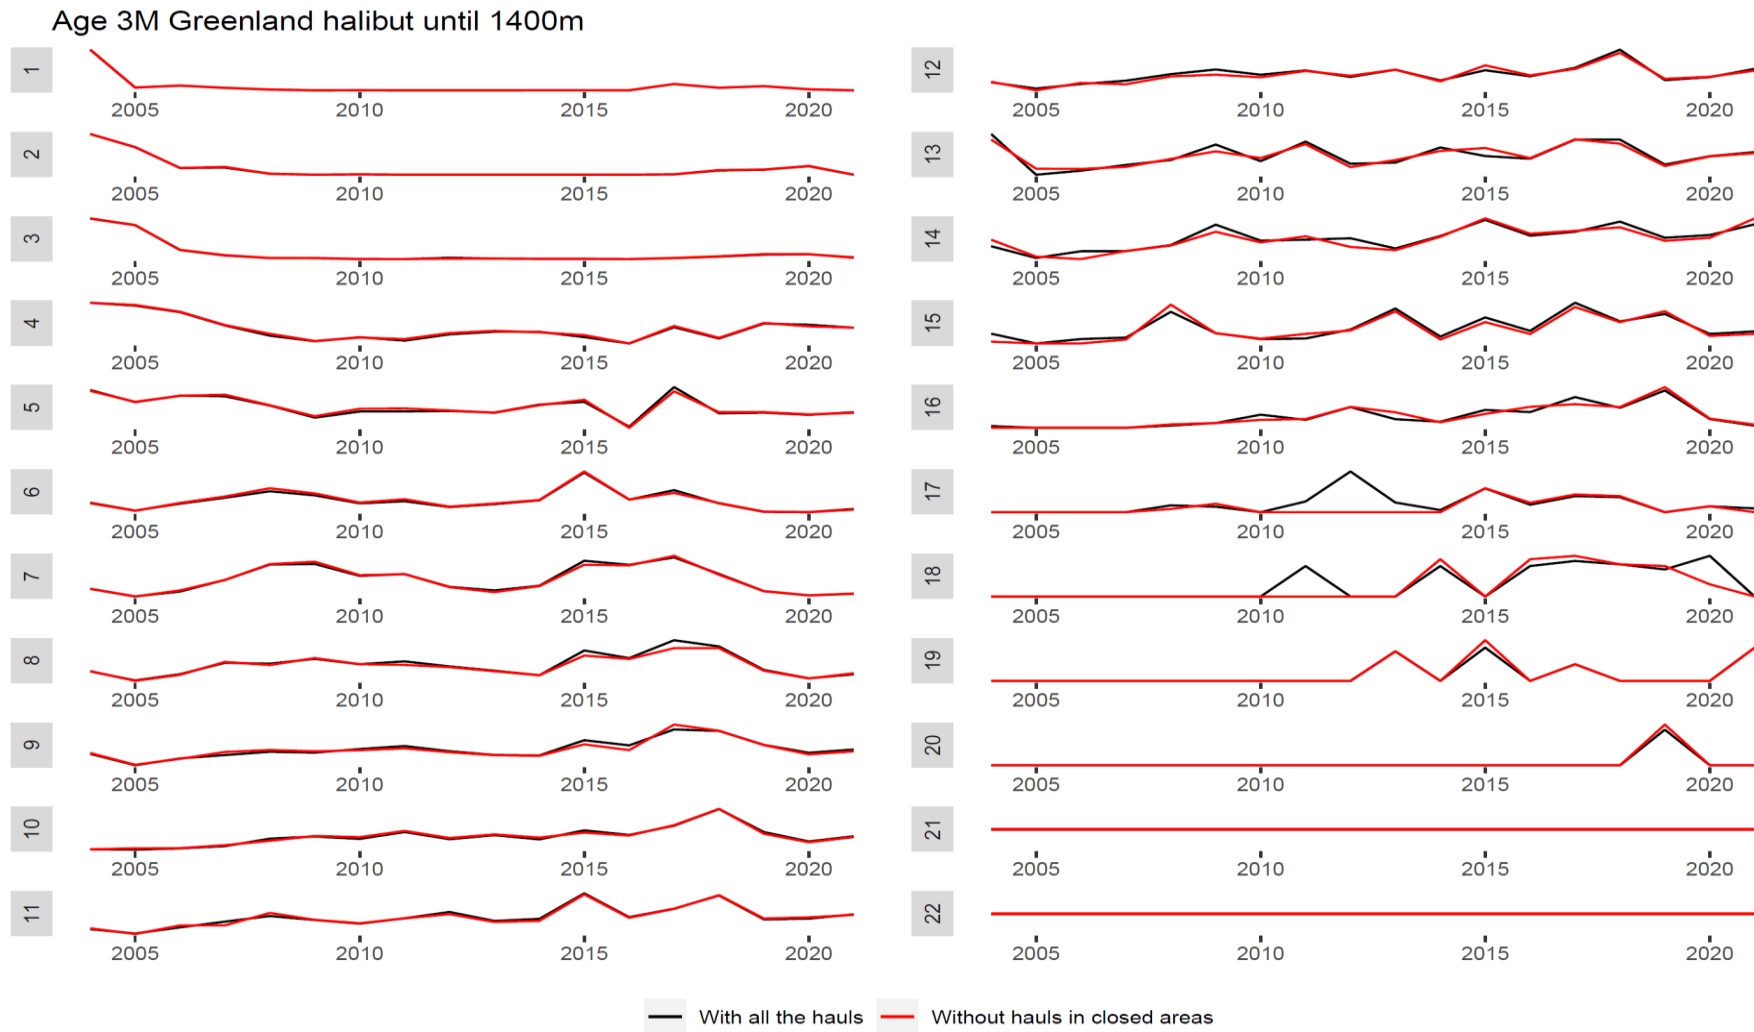

Figure 7b. Age distribution by year (2004-2021) of the Greenland halibut in 3M until 1400 meters with and without the closed areas.

Biomass 3M American plaice until 700m

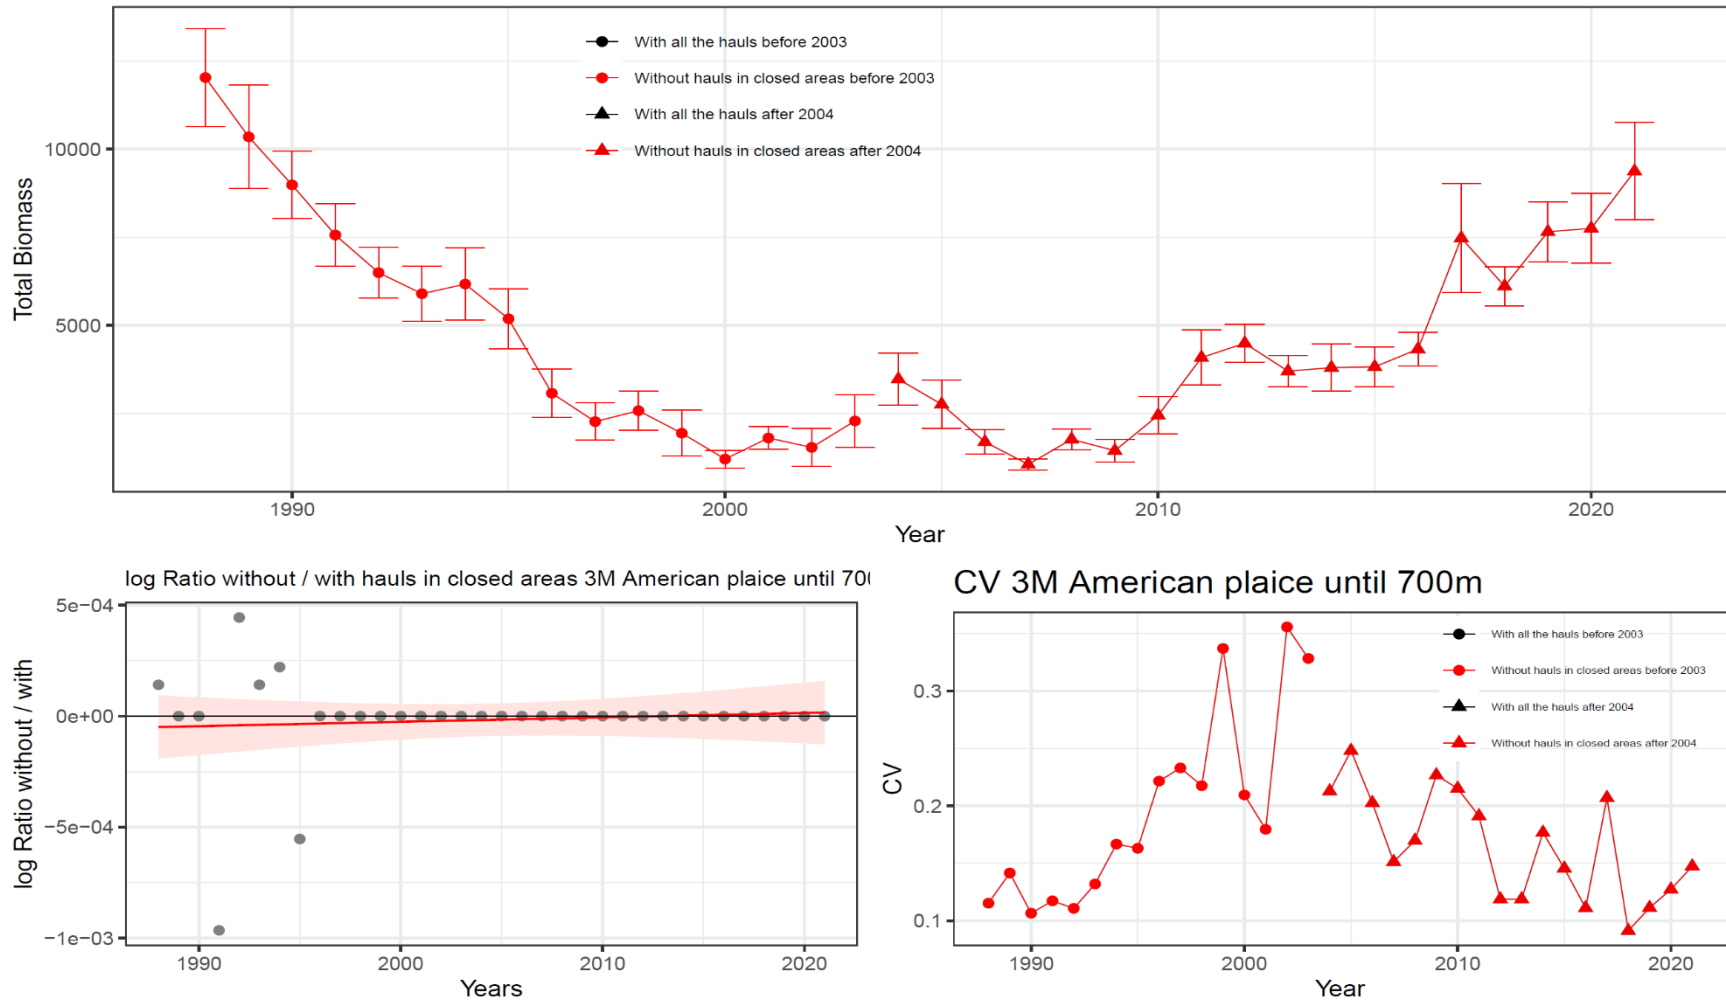

Figure 8. Biomass and SD by year (1988-2021) of the American plaice in 3M until 700 meters with and without the closed areas. Top plot: total biomass by year. Bottom left plot: log-ratio plot (indicating the relative bias caused by removing data from the protected areas and the GAM smoother trend line and 95% confidence intervals). Bottom right plot: CV of the biomass (SD/biomass).

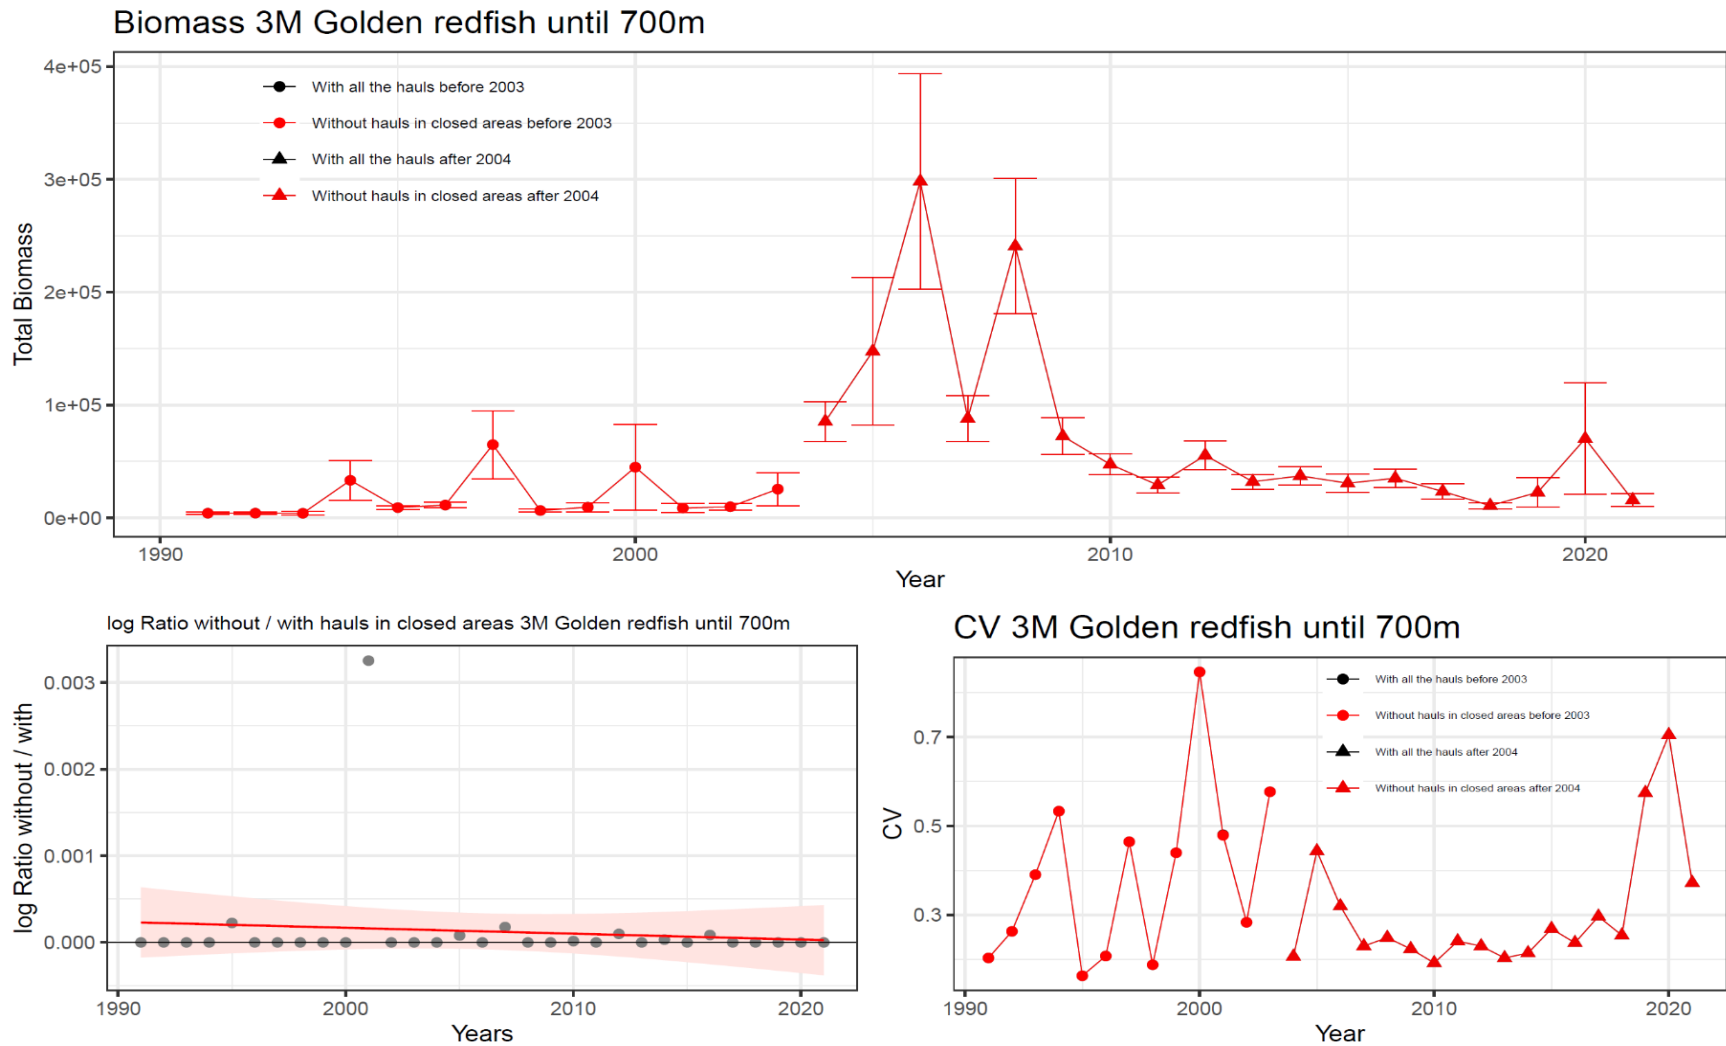

Figure 9. Biomass and SD by year (1991-2021) of the golden redfish in 3M until 700 meters with and without the closed areas. Top plot: total biomass by year. Bottom left plot: log-ratio plot (indicating the relative bias caused by removing data from the protected areas and the GAM smoother trend line and 95% confidence intervals). Bottom right plot: CV of the biomass (SD/biomass).

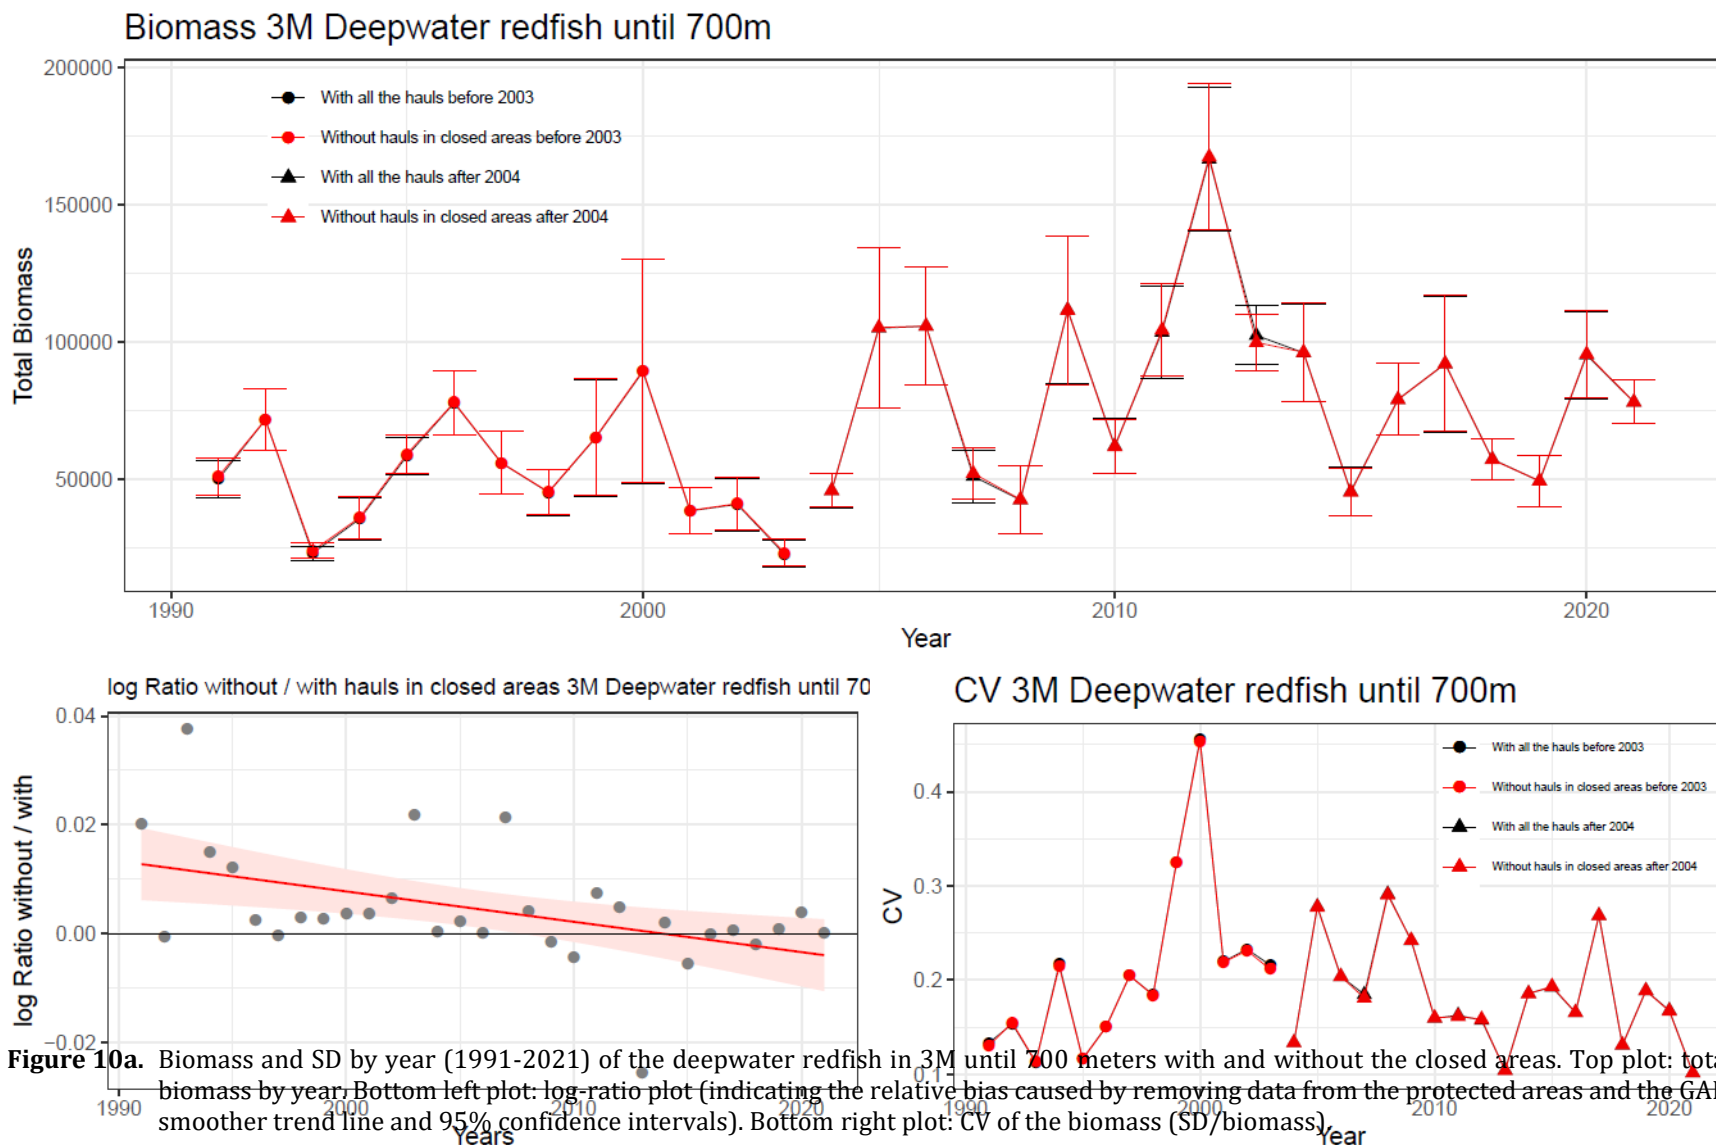

Figure 10a. Biomass and SD by year (1991-2021) of the deepwater redfish in 3M until 700 meters with and without the closed areas. Top plot: total biomass by year. Bottom left plot: log-ratio plot (indicating the relative bias caused by removing data from the protected areas and the GAM smoother trend line and 95% confidence intervals). Bottom right plot: CV of the biomass (SD/biomass).

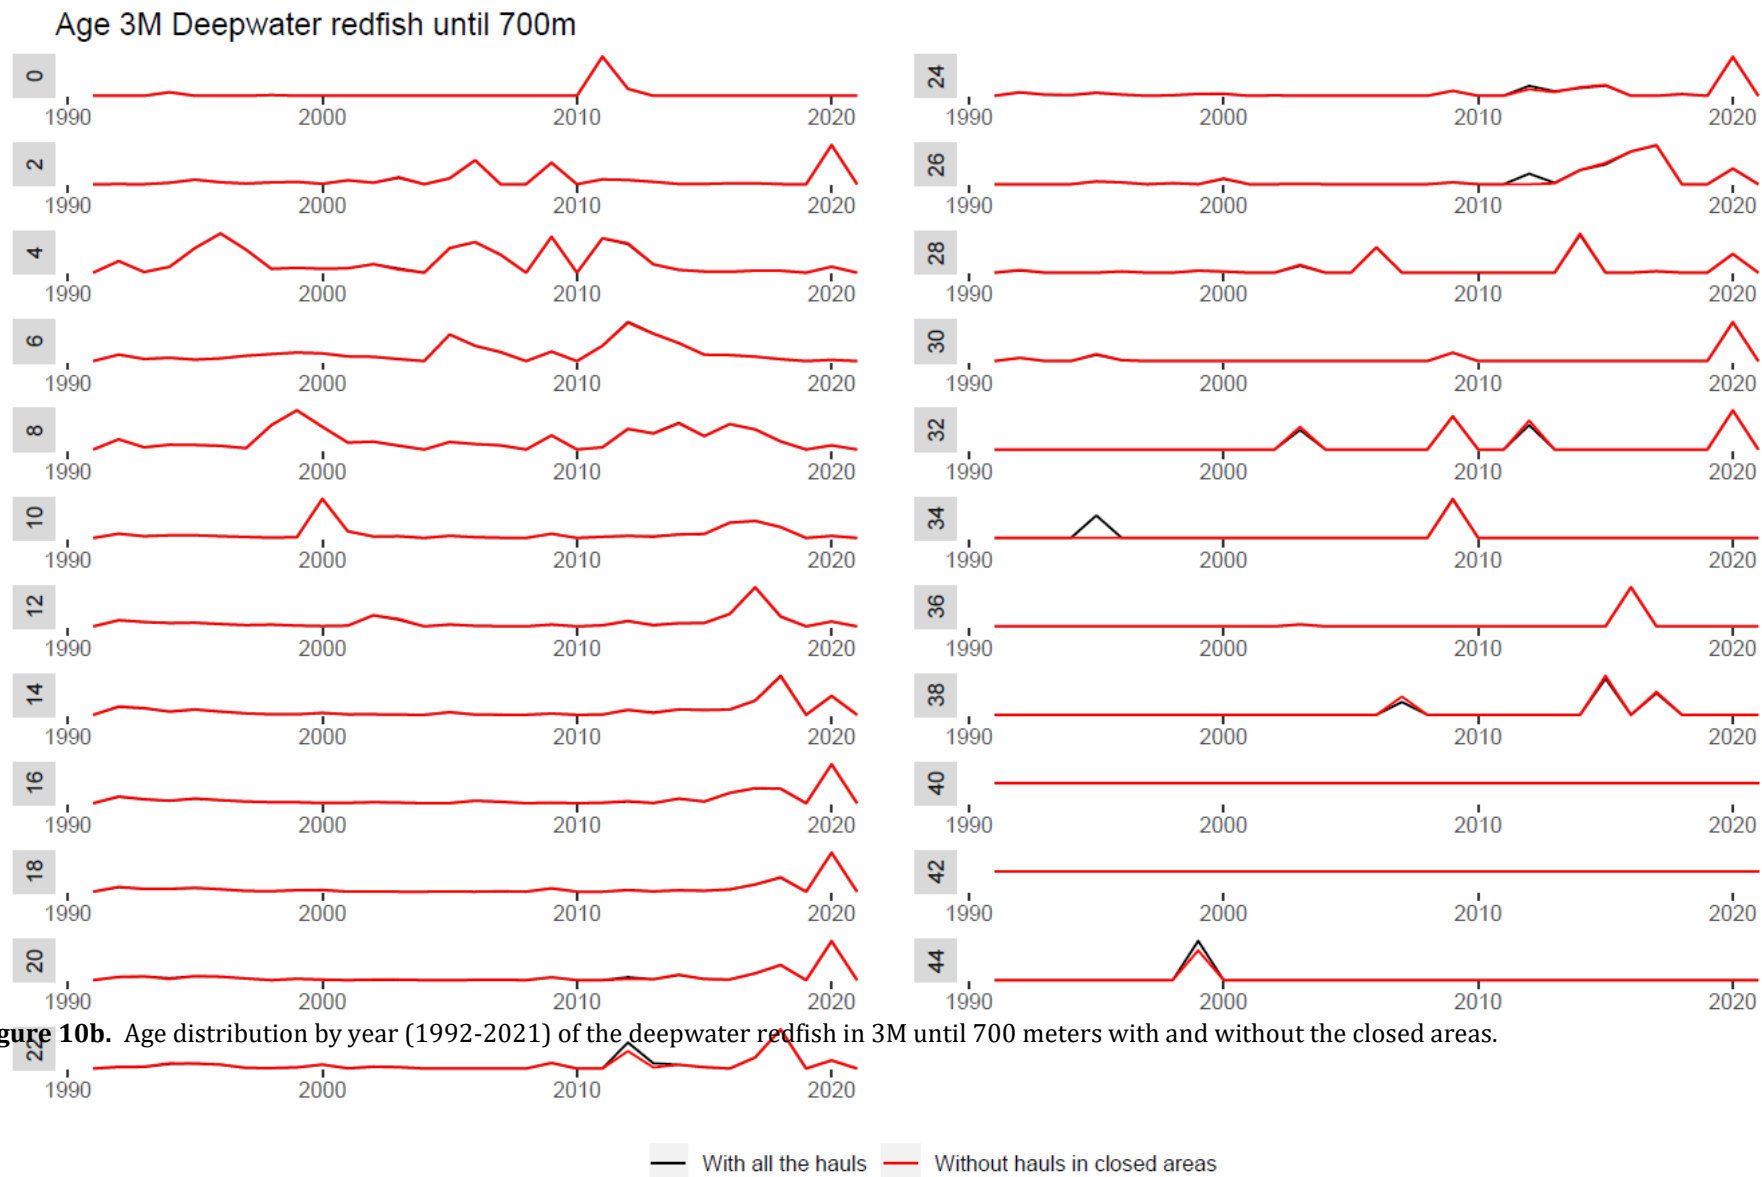

Figure 10b. Age distribution by year (1992-2021) of the deepwater redfish in 3M until 700 meters with and without the closed areas.

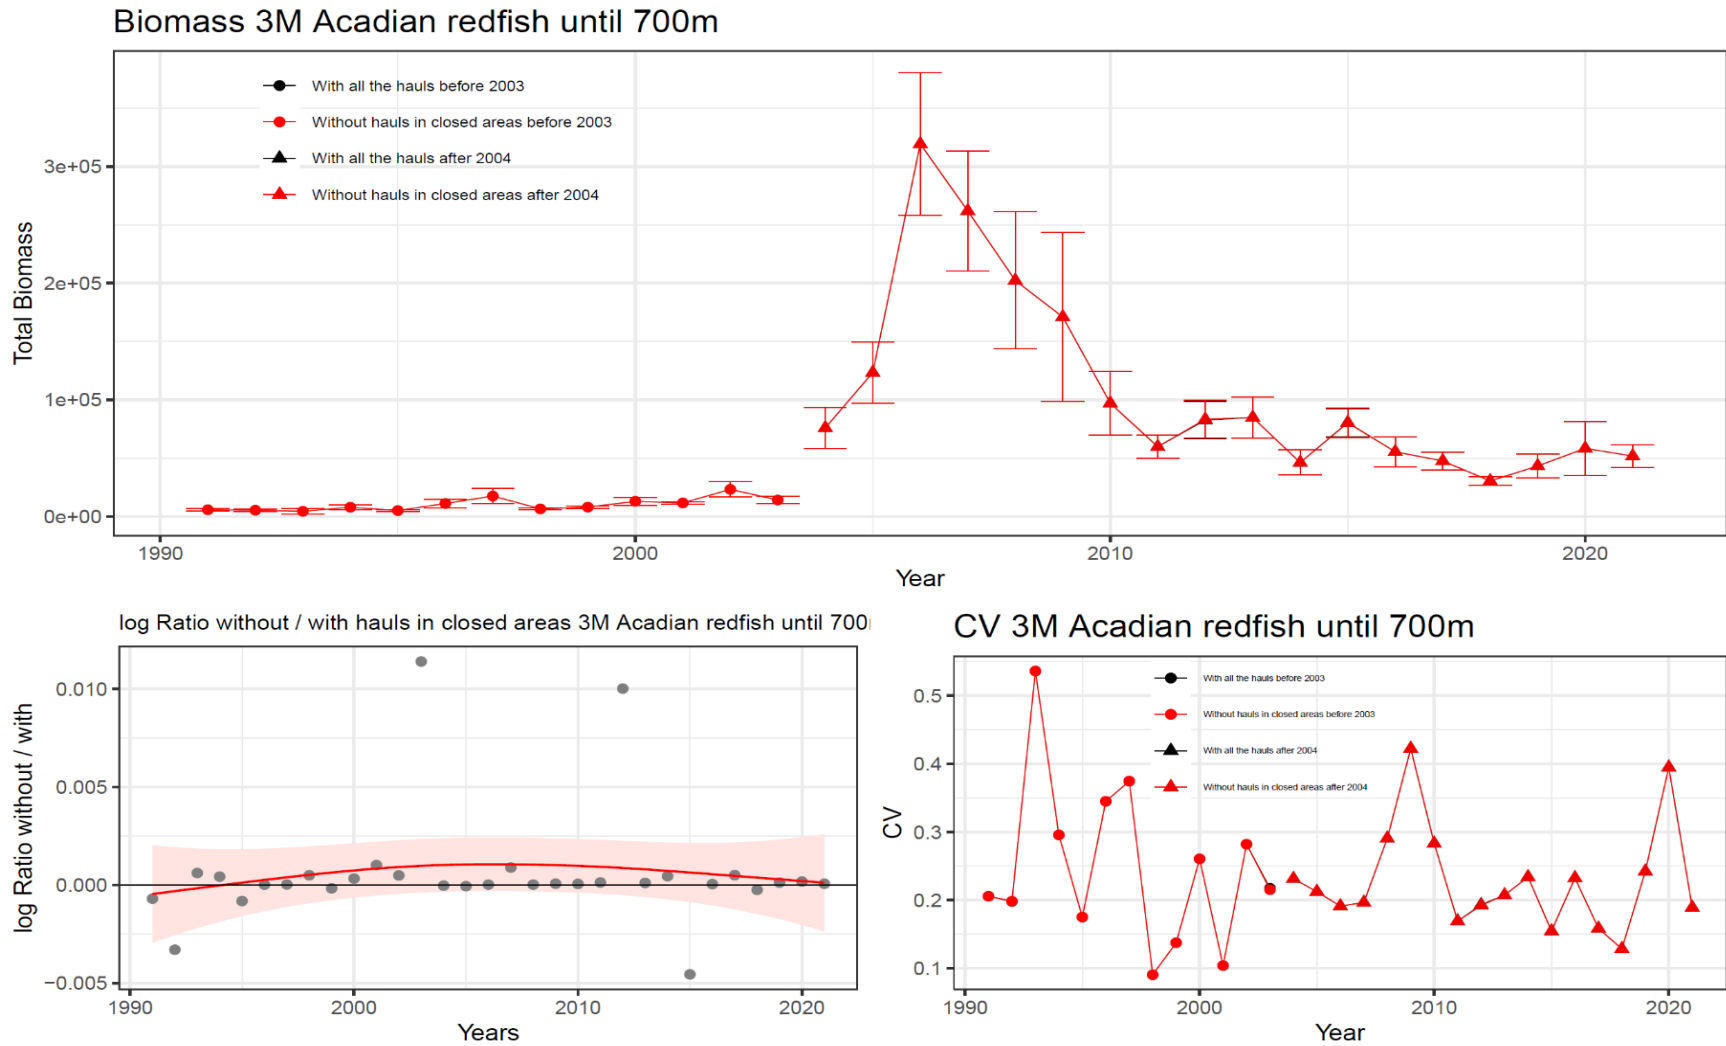

Figure 11. Biomass and SD by year (1991-2021) of the Acadian redfish in 3M until 700 meters with and without the closed areas. Top plot: total biomass by year. Bottom left plot: log-ratio plot (indicating the relative bias caused by removing data from the protected areas and the GAM smoother trend line and 95% confidence intervals). Bottom right plot: CV of the biomass (SD/biomass).

Biomass 3M Roughhead grenadier until 700m

log Ratio without / with hauls in closed areas 3M Roughhead grenadier until 700m

CV 3M Roughhead grenadier until 700m

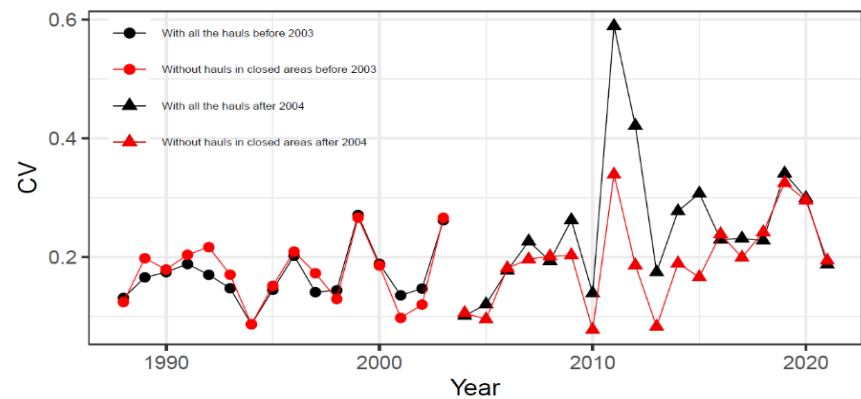

Figure 12a. Biomass and SD by year (1988-2021) of the roughhead grenadier in 3M until 700 meters with and without the closed areas. Top plot: total biomass by year. Bottom left plot: log-ratio plot (indicating the relative bias caused by removing data from the protected areas and the GAM smoother trend line and 95% confidence intervals). Bottom right plot: CV of the biomass (SD/biomass).

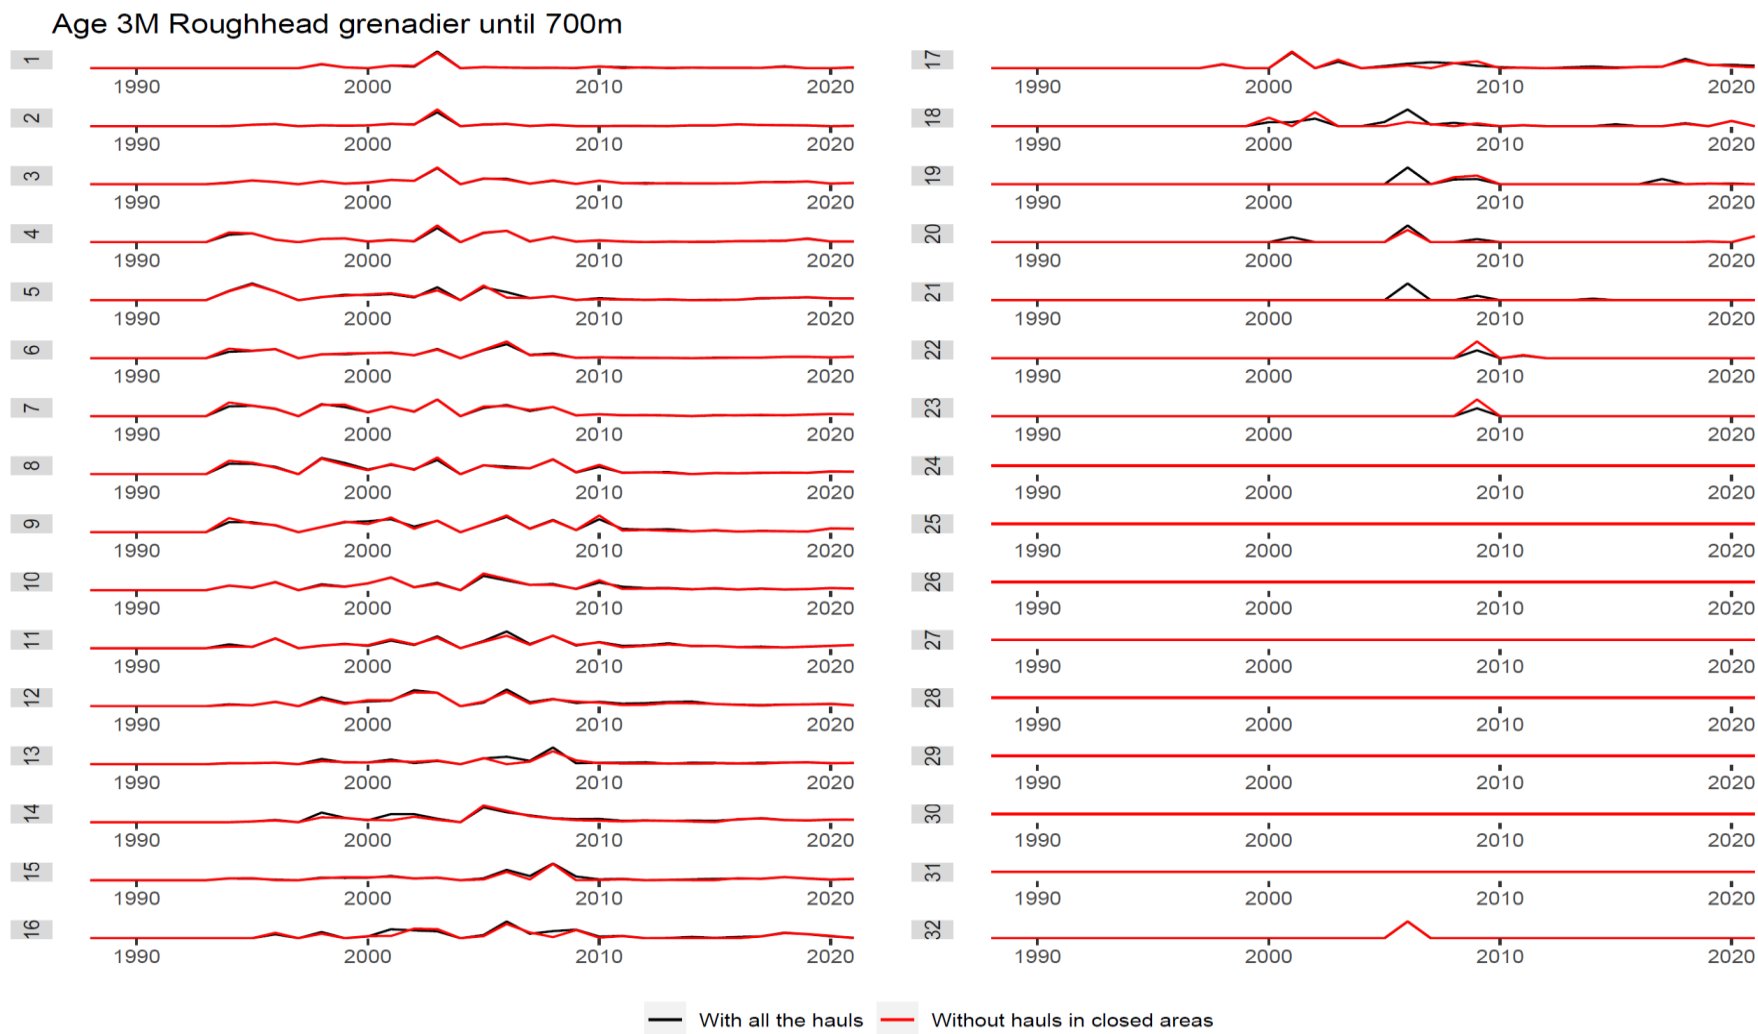

Figure 12b. Age distribution by year (1994-2021) of the roughhead grenadier in 3M until 700 meters with and without the closed areas.

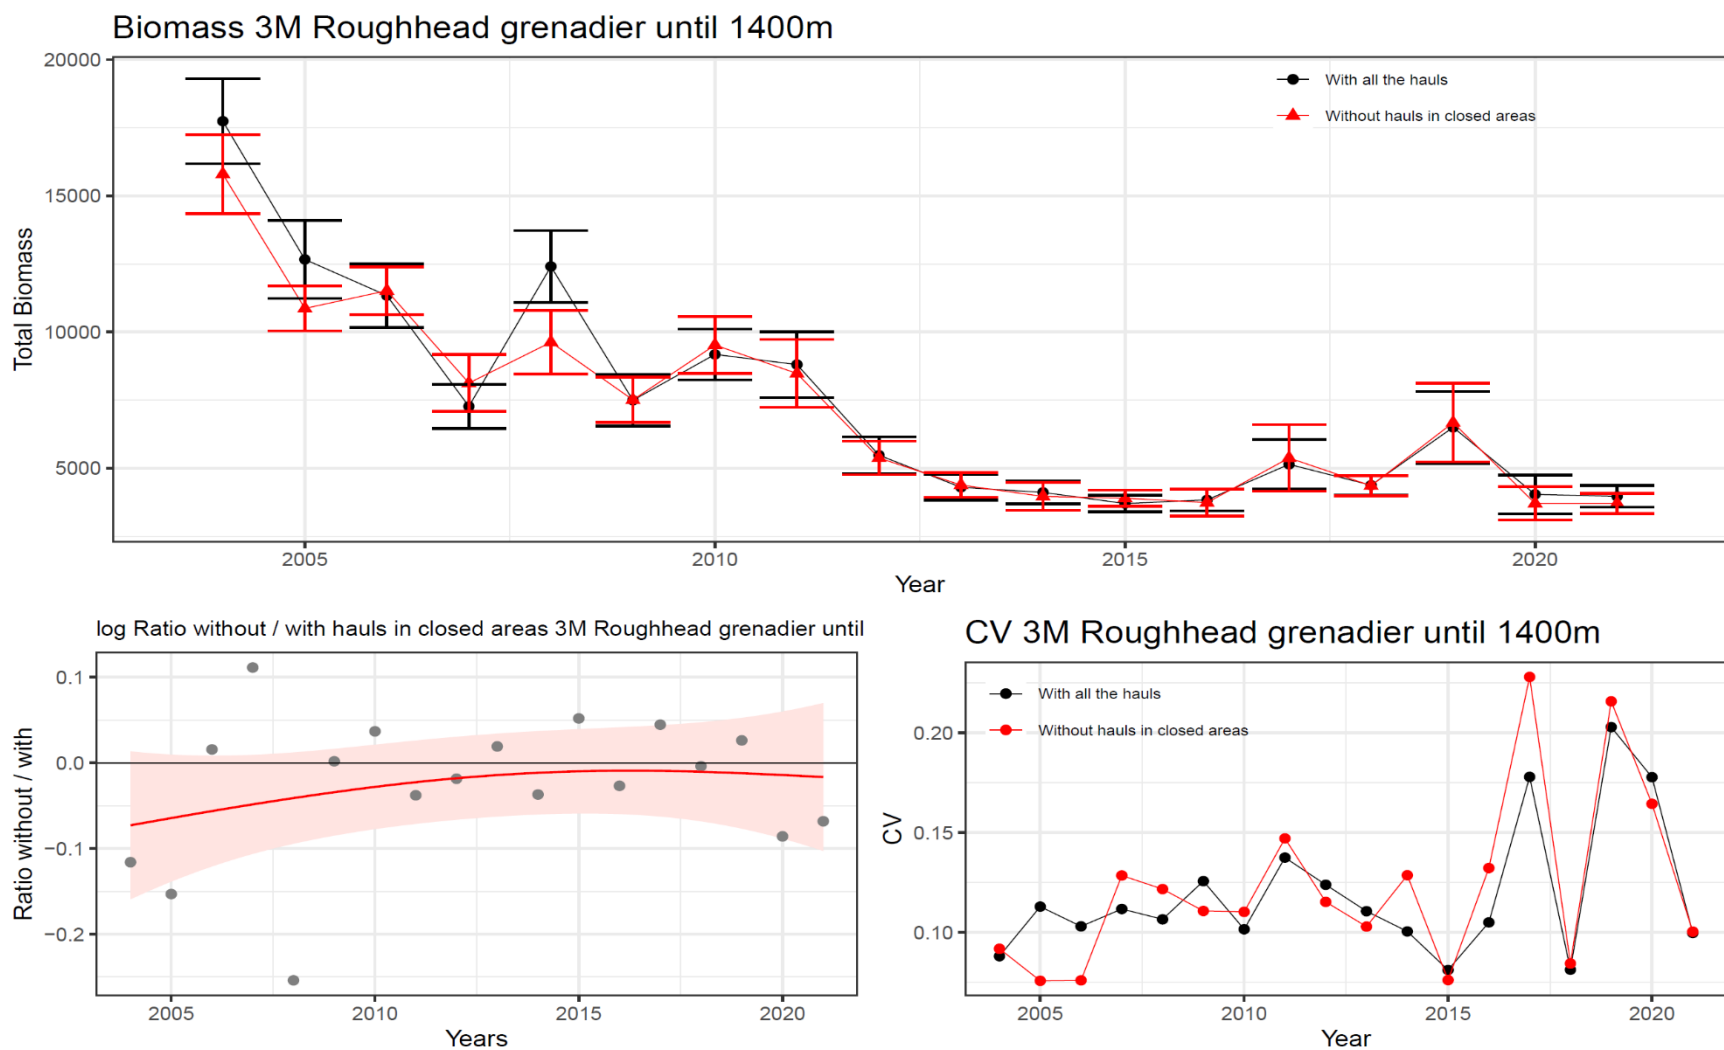

Figure 13a. Biomass and SD by year (2004-2021) of the roughhead grenadier in 3M until 1400 meters with and without the closed areas. Top plot: total biomass by year. Bottom left plot: log-ratio plot (indicating the relative bias caused by removing data from the protected areas and the GAM smoother trend line and 95% confidence intervals). Bottom right plot: CV of the biomass (SD/biomass).

Figure 13b. Age distribution by year (2004-2021) of the roughhead grenadier in 3M until 1400 meters with and without the closed areas.

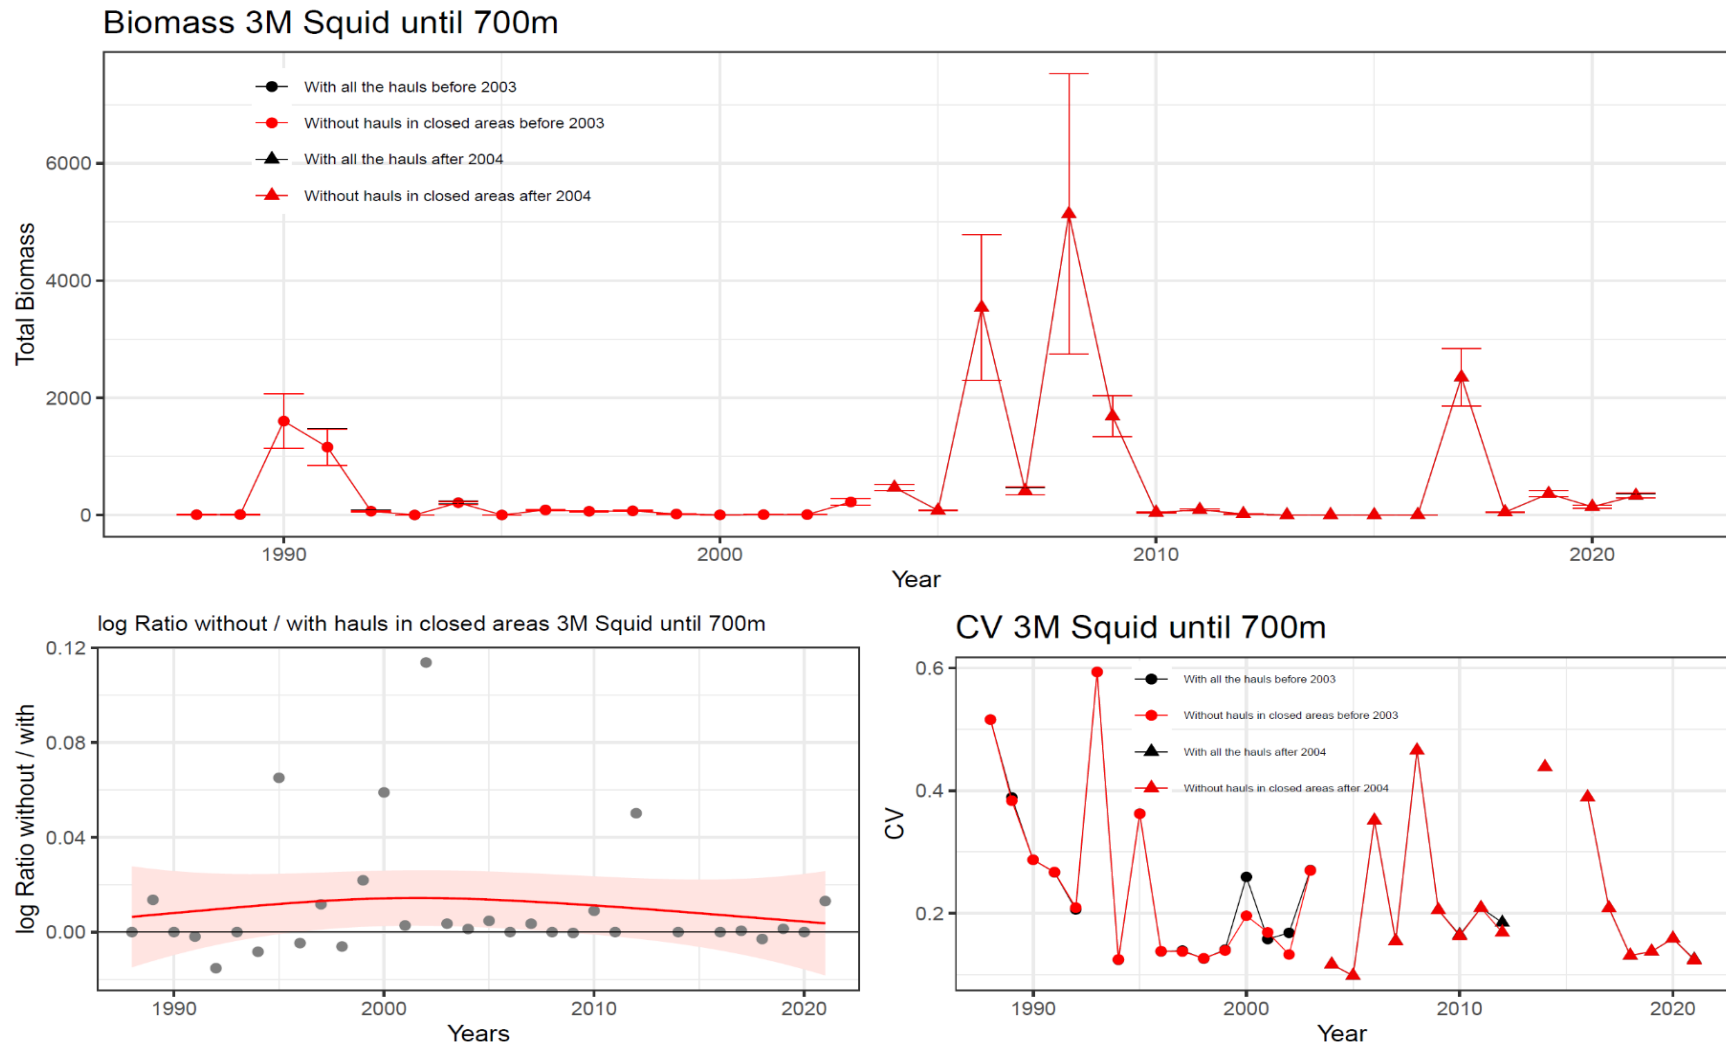

Figure 14. Biomass and SD by year (1988-2021) of the squid in 3M until 700 meters with and without the closed areas. Top plot: total biomass by year. Bottom left plot: log-ratio plot (indicating the relative bias caused by removing data from the protected areas and the GAM smoother trend line and 95% confidence intervals). Bottom right plot: CV of the biomass (SD/biomass).

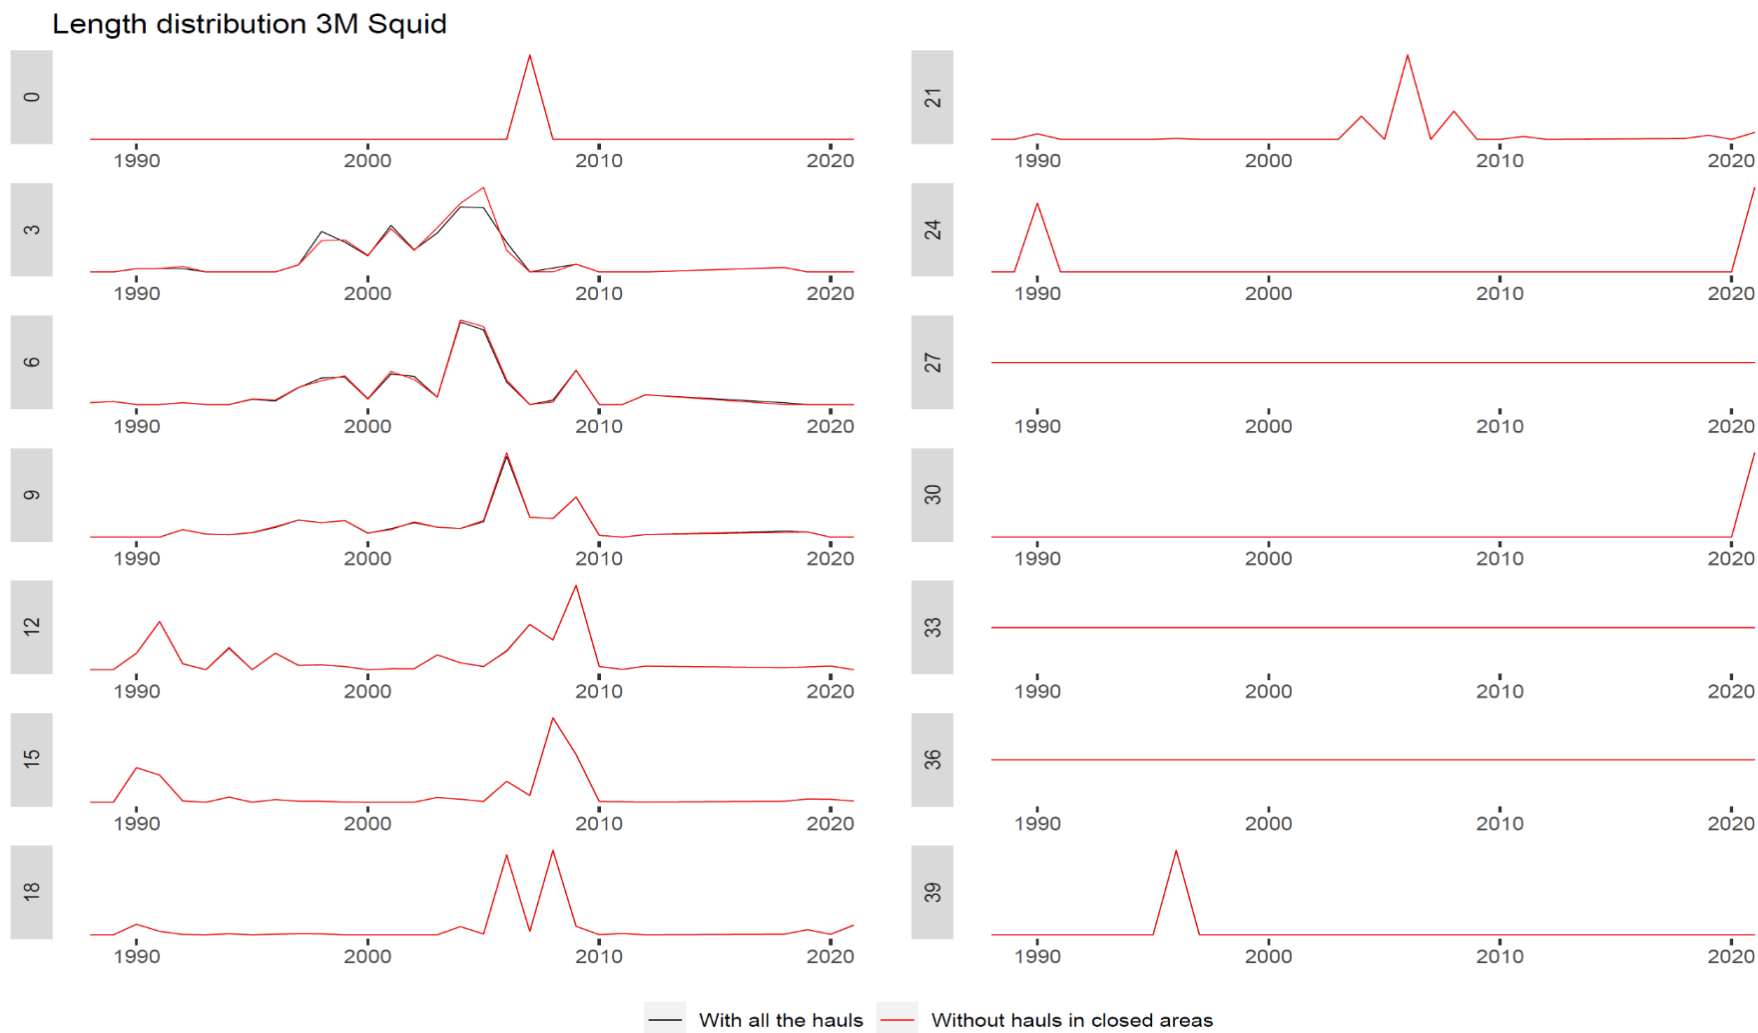

Figure 15. Age distribution by year (1988-2021) of the squid in 3M until 700 meters with and without the closed areas.

Biomass 3NO Atlantic cod

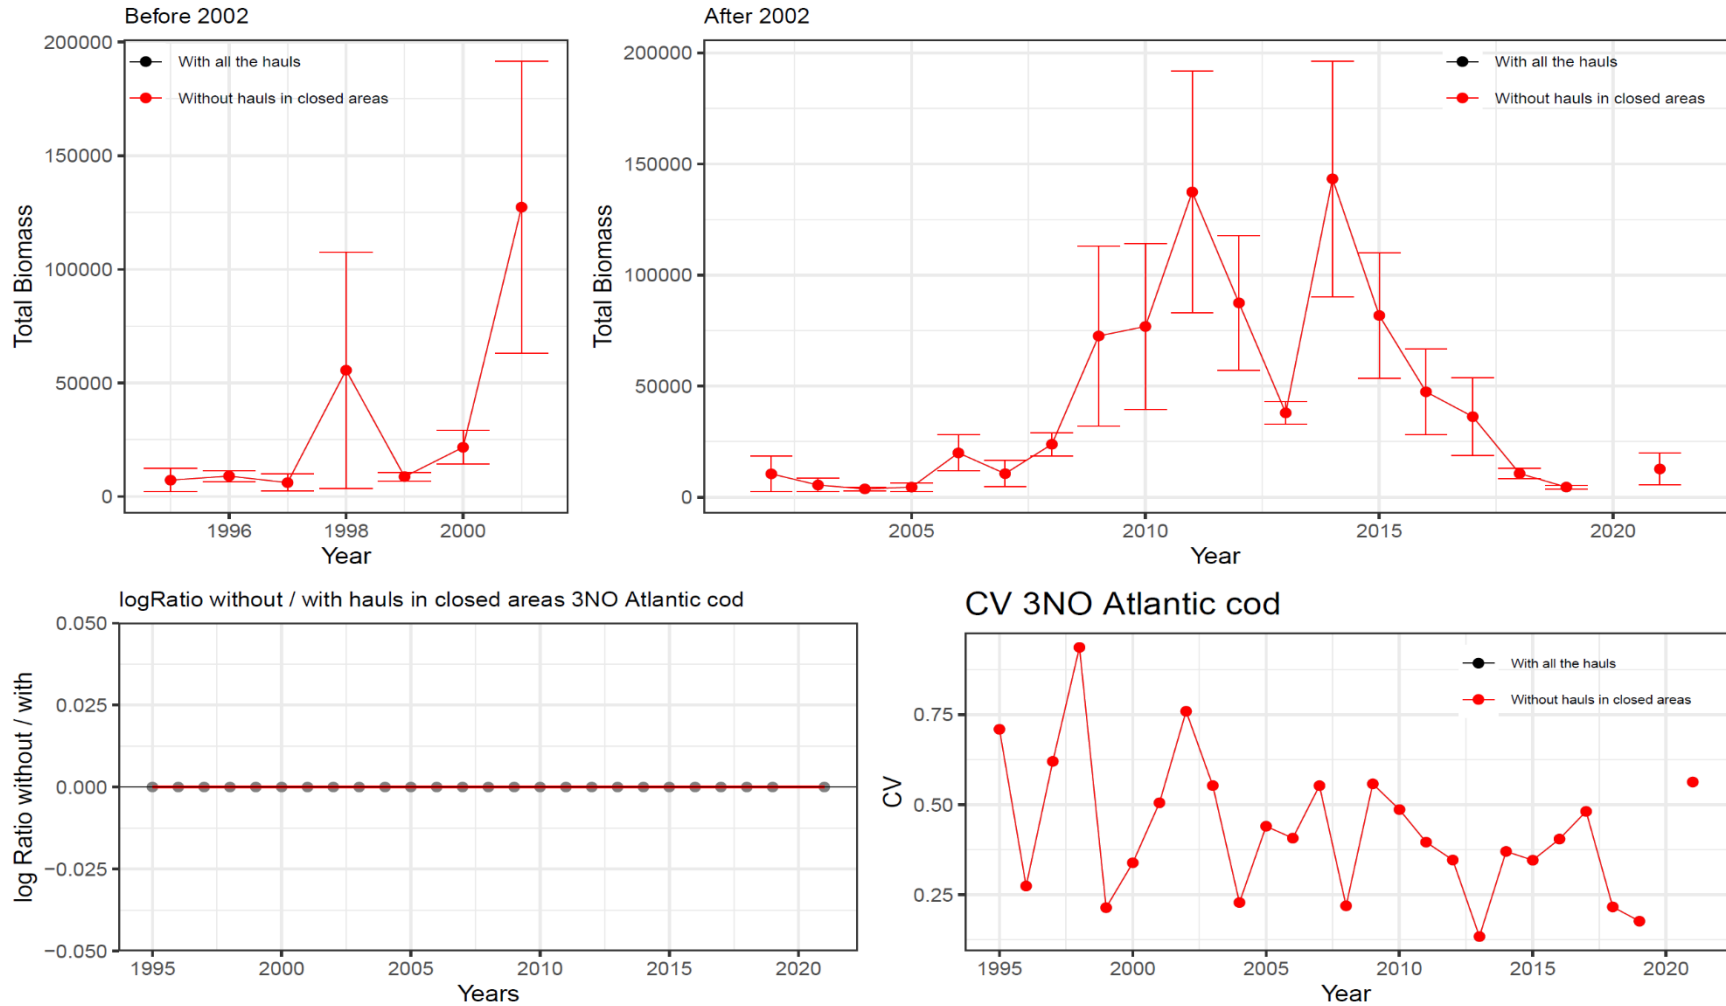

Figure 16. Biomass and SD by year (1995-2021) of the Atlantic cod in 3NO with and without the closed areas. Top plot: total biomass by year. Bottom left plot: log-ratio plot (indicating the relative bias caused by removing data from the protected areas and the GAM smoother trend line and 95% confidence intervals). Bottom right plot: CV of the biomass (SD/biomass).

Biomass 3NO Greenland halibut

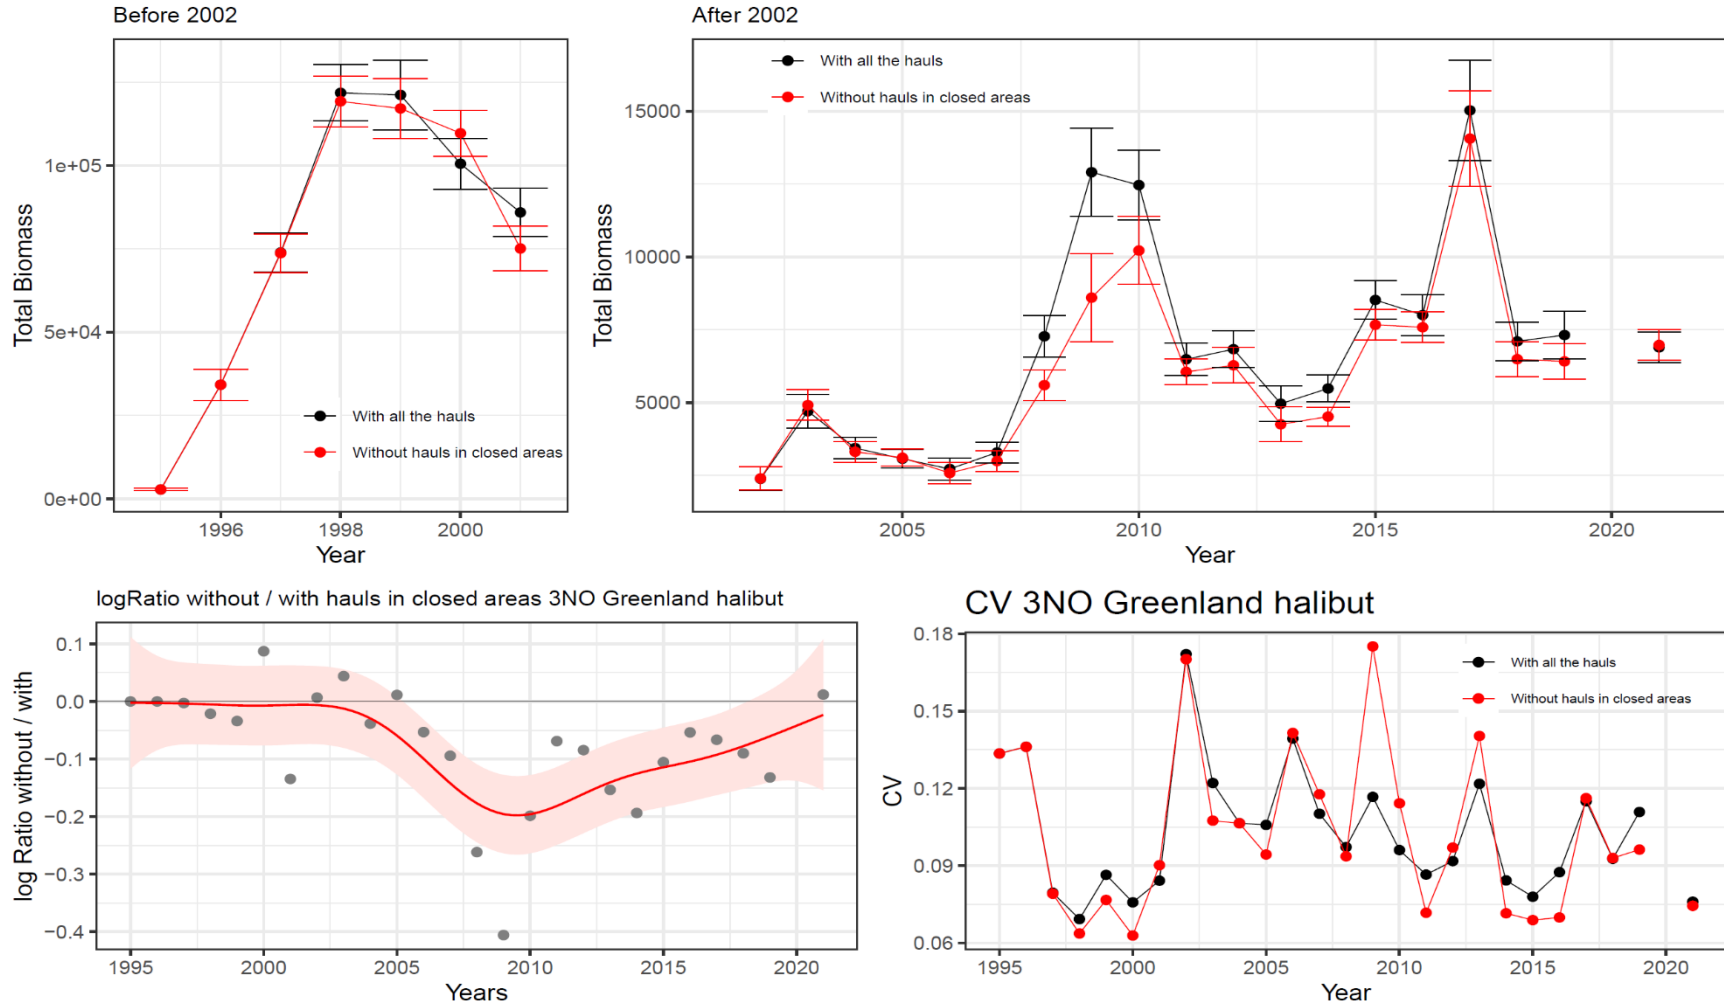

Figure 17. Biomass and SD by year (1995-2021) of the Greenland halibut in 3NO with and without the closed areas. Top plot: total biomass by year. Bottom left plot: log-ratio plot (indicating the relative bias caused by removing data from the protected areas and the GAM smoother trend line and 95% confidence intervals). Bottom right plot: CV of the biomass (SD/biomass).

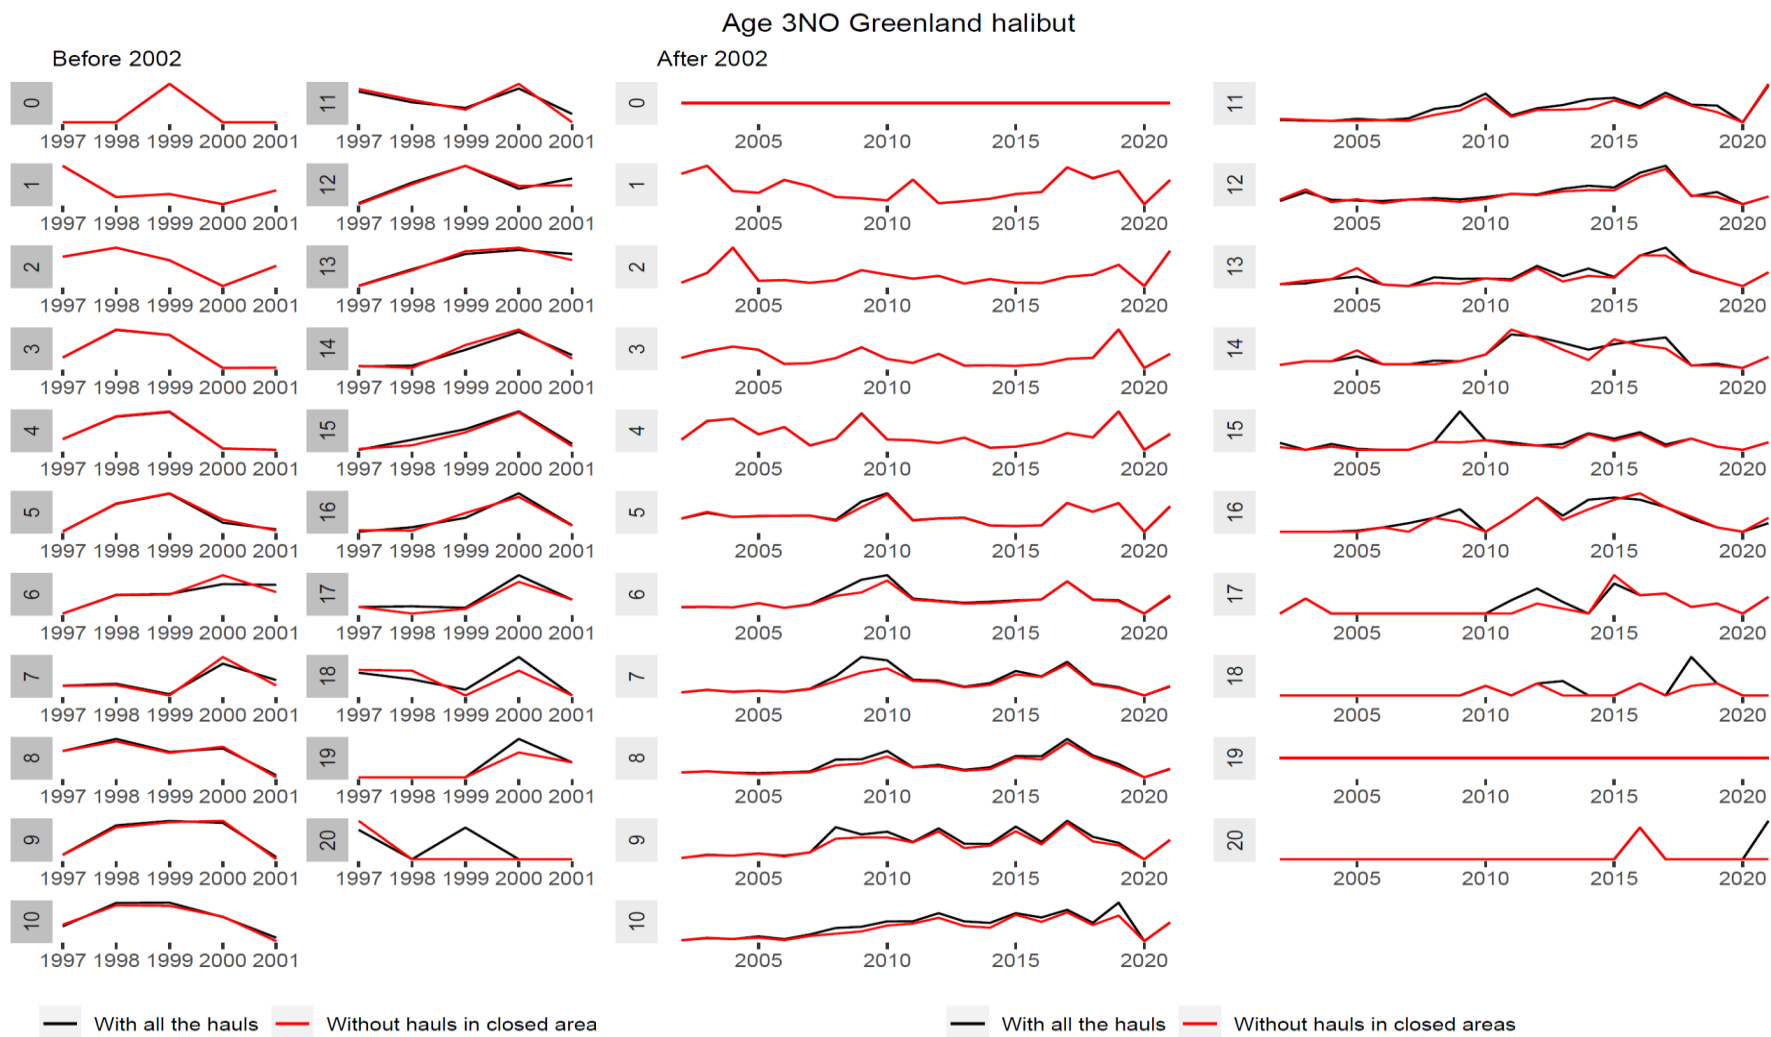

Figure 18. Age distribution by year (1995-2021) of the Greenland halibut in 3NO with and without the closed areas.

Biomass 3NO American plaice

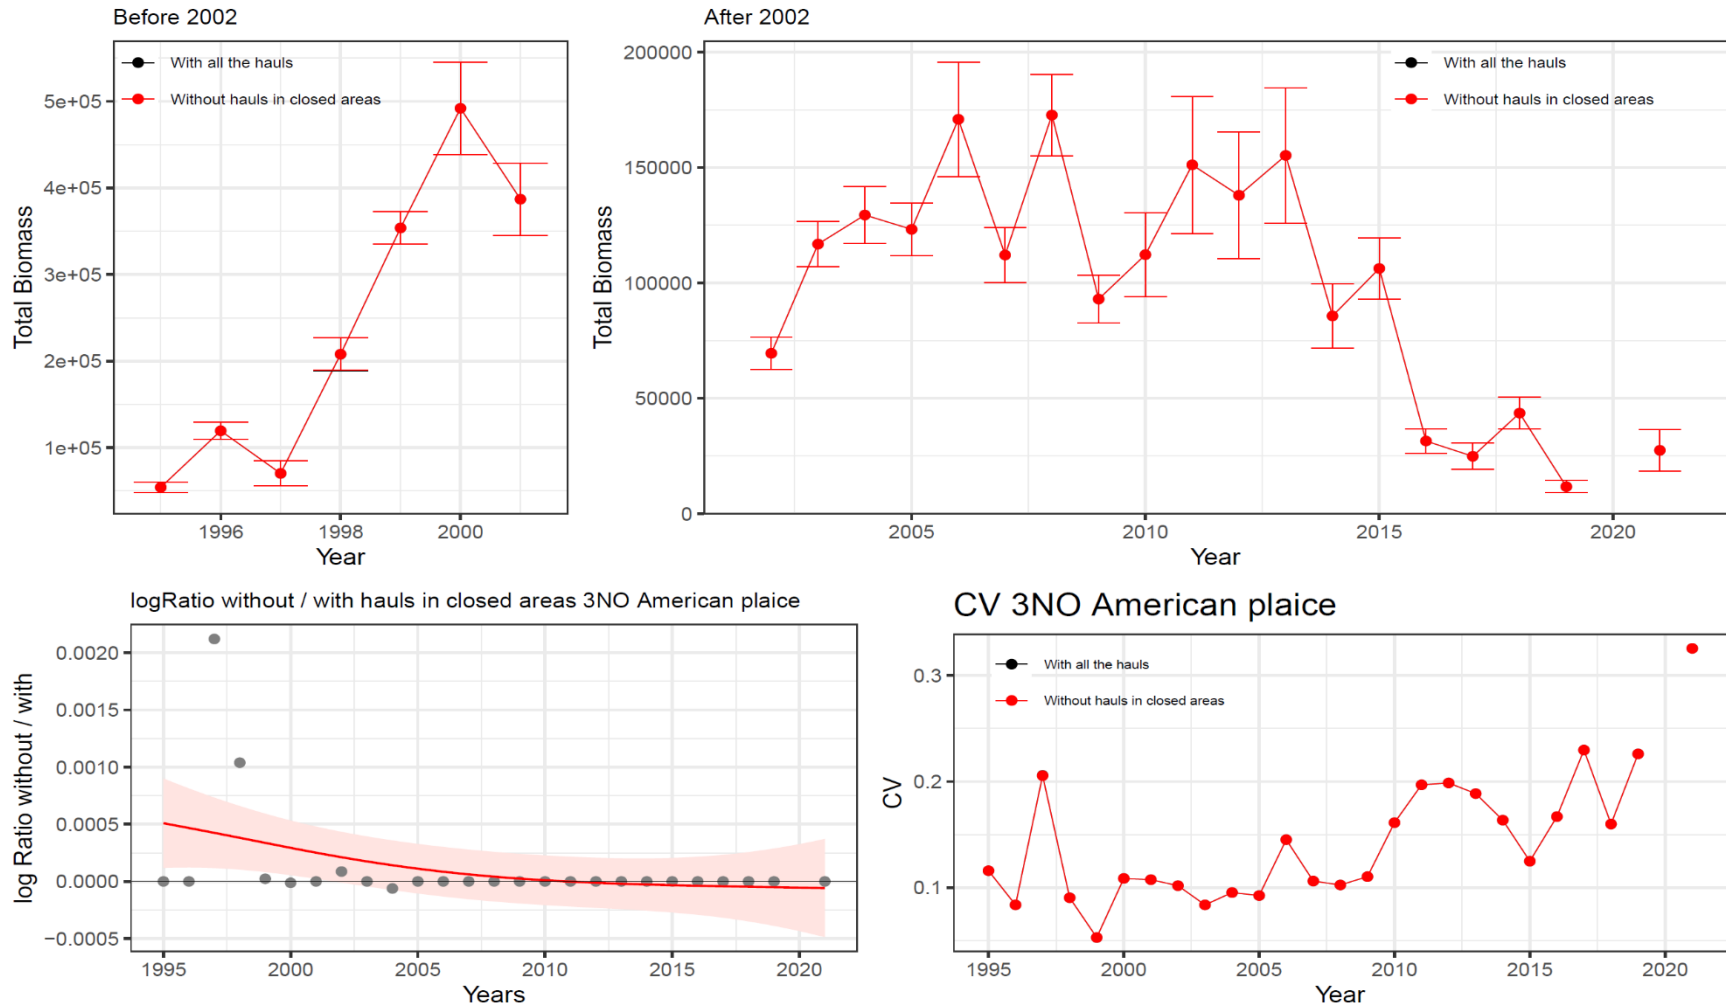

Figure 19. Biomass and SD by year (1995-2020) of the American plaice in 3NO with and without the closed areas. Top plot: total biomass by year. Bottom left plot: log-ratio plot (indicating the relative bias caused by removing data from the protected areas and the GAM smoother trend line and 95% confidence intervals). Bottom right plot: CV of the biomass (SD/biomass).

Biomass 3NO Redfish

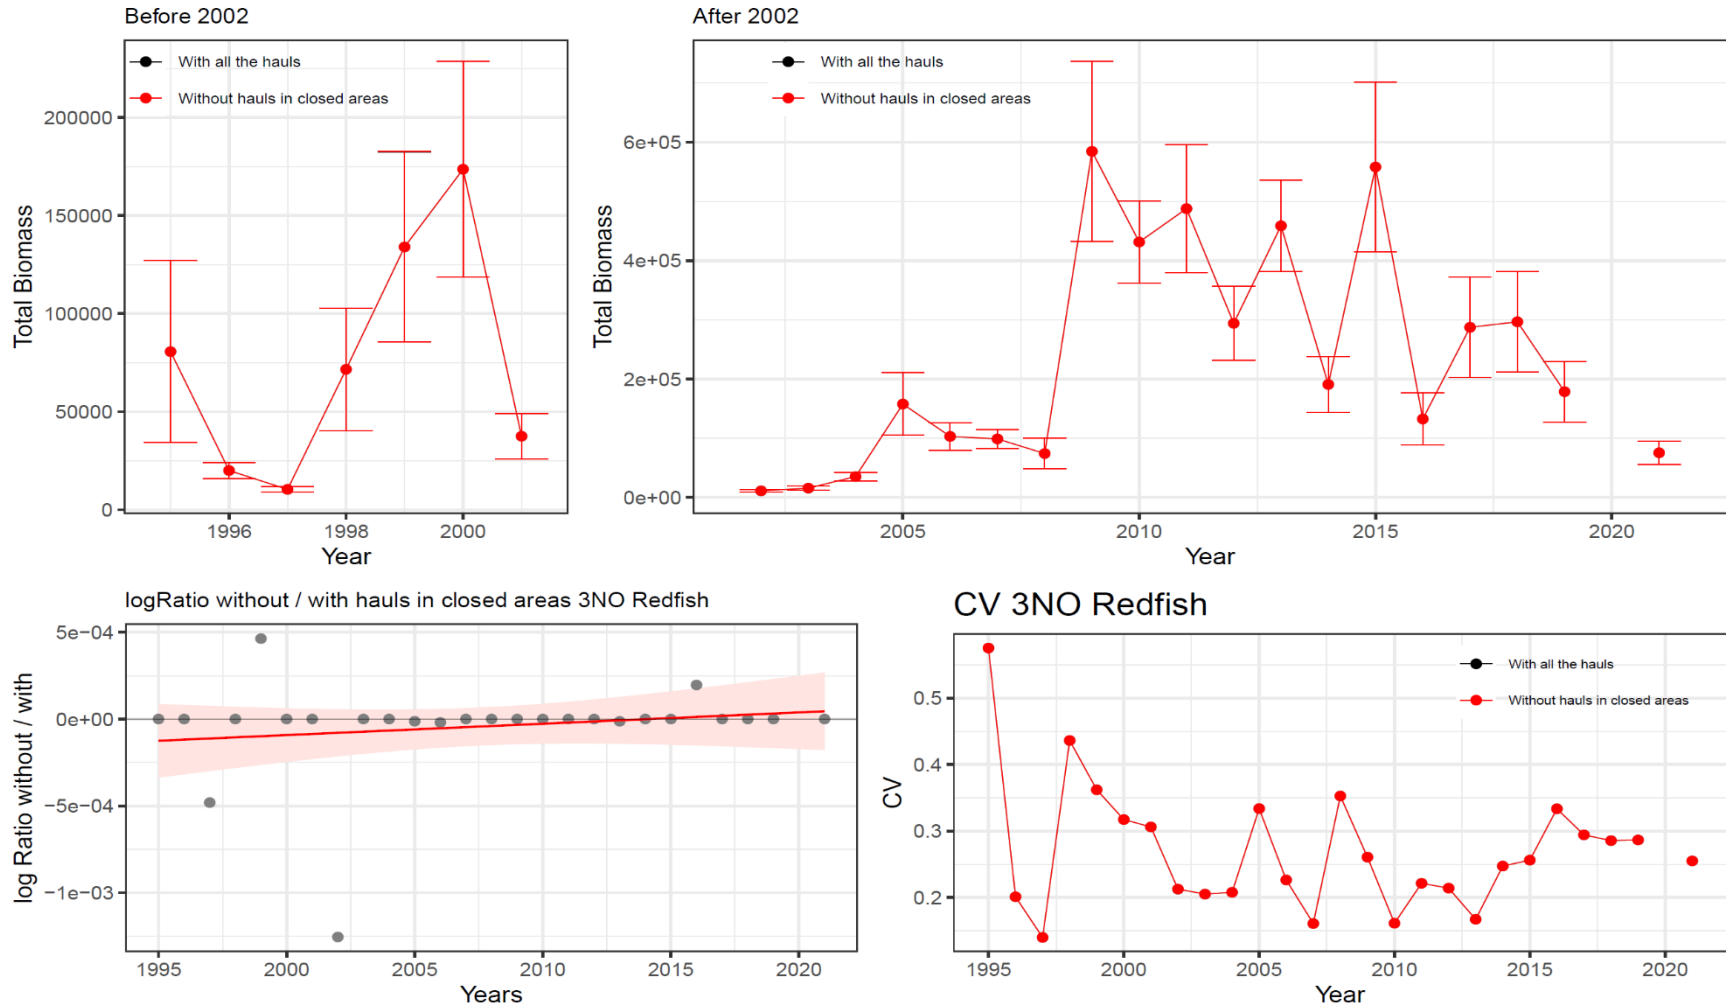

Figure 20. Biomass and SD by year (1995-2021) of the redfish in 3NO with and without the closed areas. Top plot: total biomass by year. Bottom left plot: log-ratio plot (indicating the relative bias caused by removing data from the protected areas and the GAM smoother trend line and 95% confidence intervals). Bottom right plot: CV of the biomass (SD/biomass).

Biomass 3NO Roughhead grenadier

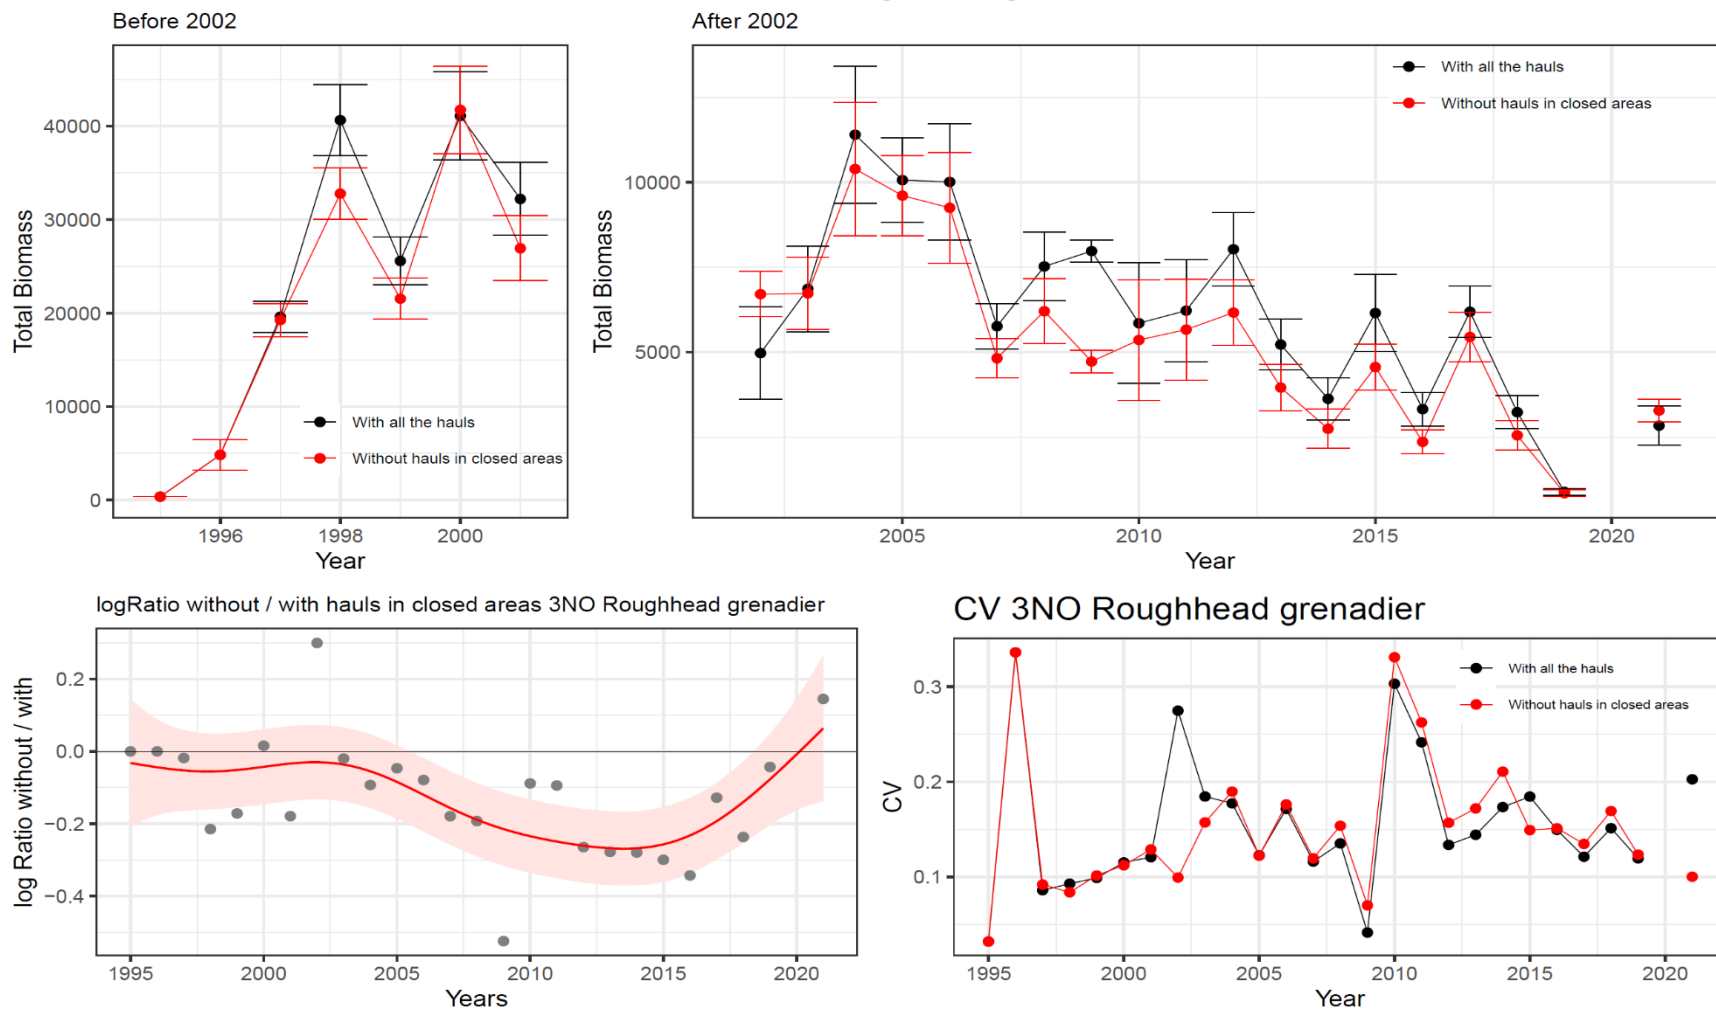

Figure 21. Biomass and SD by year (1995-2021) of the roughhead grenadier in 3NO with and without the closed areas. Top plot: total biomass by year. Bottom left plot: log-ratio plot (indicating the relative bias caused by removing data from the protected areas and the GAM smoother trend line and 95% confidence intervals). Bottom right plot: CV of the biomass (SD/biomass).

Figure 22. Length distribution by year (1995-2021) of the roughhead grenadier in 3NO with and without the closed areas.

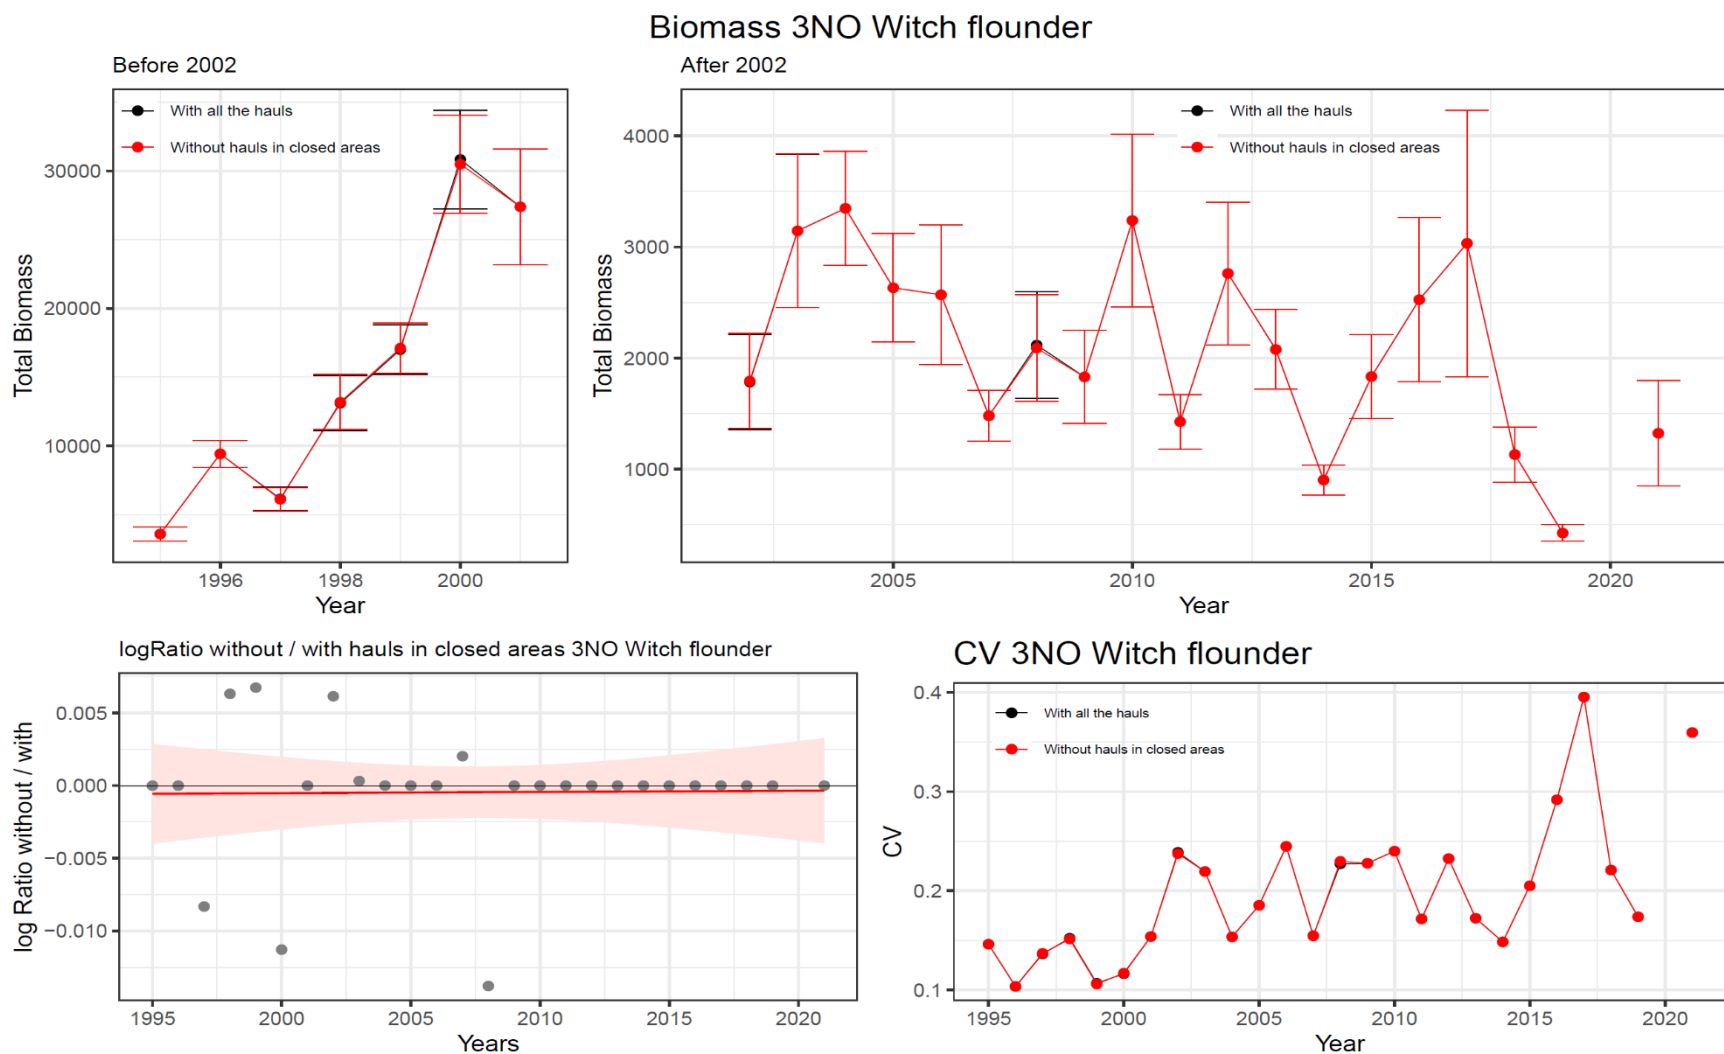

Figure 23. Biomass and SD by year (1995-2021) of the witch flounder in 3NO with and without the closed areas. Top plot: total biomass by year. Bottom left plot: log-ratio plot (indicating the relative bias caused by removing data from the protected areas and the GAM smoother trend line and 95% confidence intervals). Bottom right plot: CV of the biomass (SD/biomass).

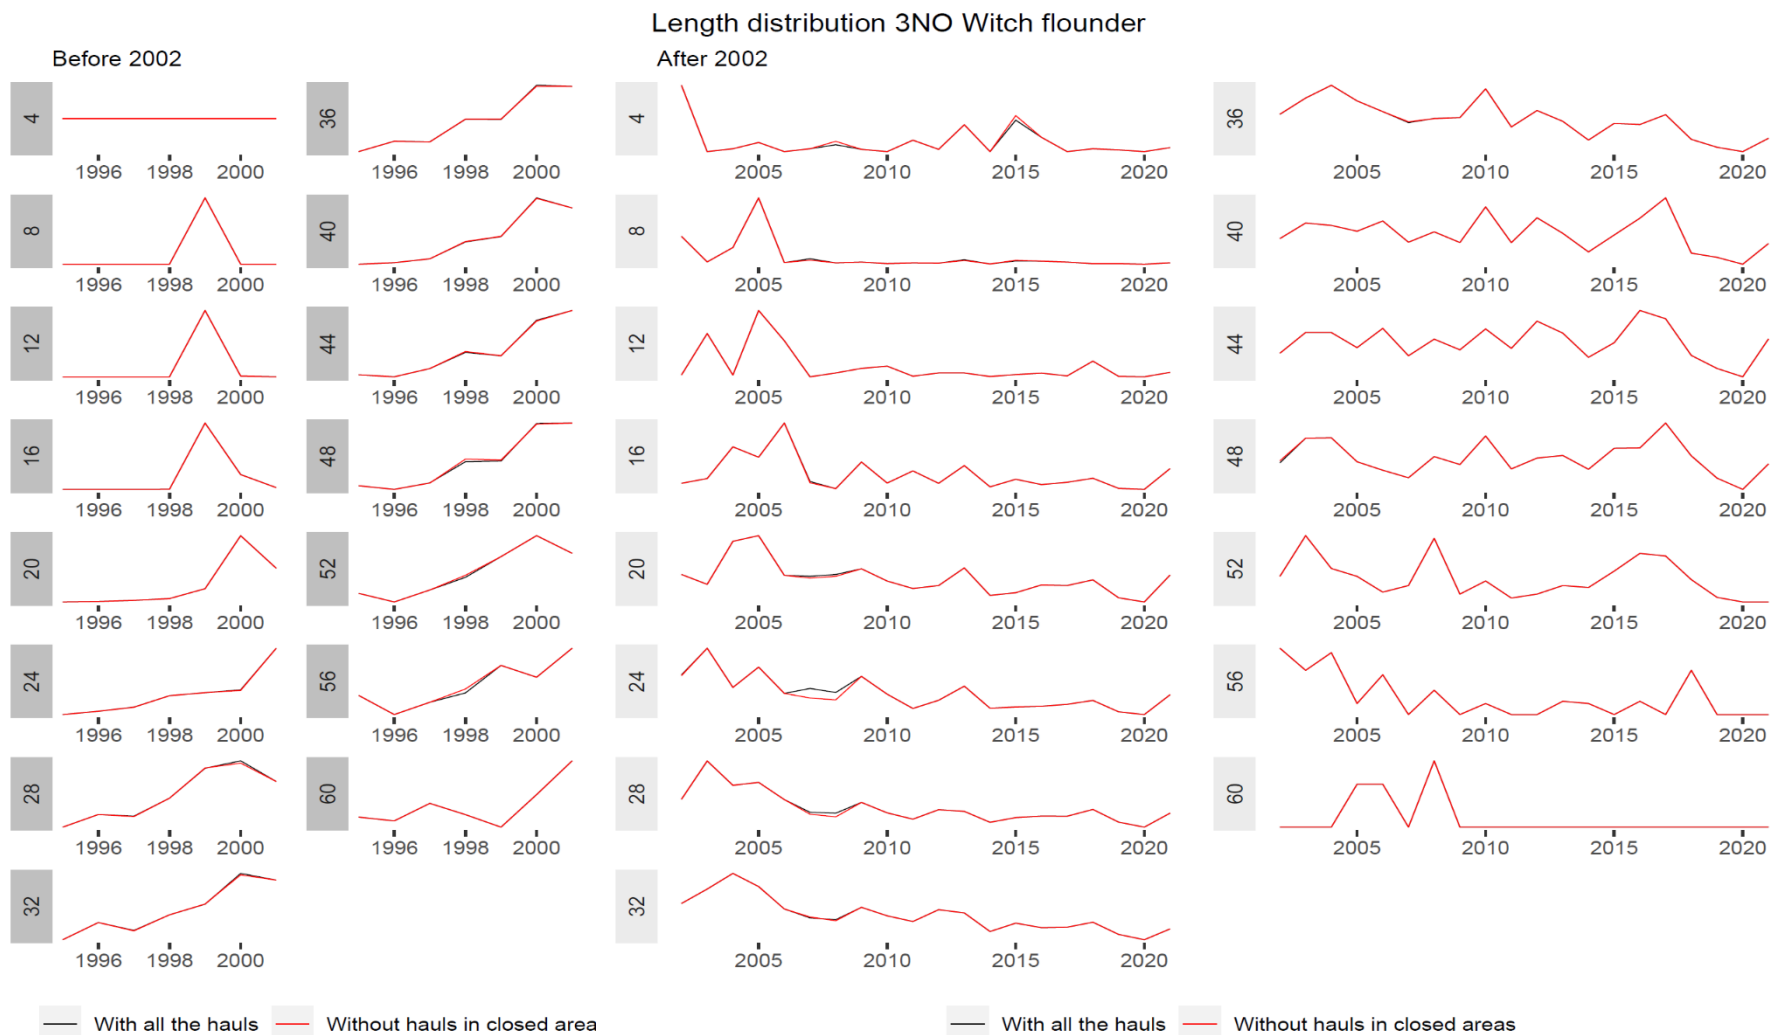

Figure 24. Length distribution by year (1995-2021) of the roughhead grenadier in 3NO with and without the closed areas.

Biomass 3NO Yellowtail flounder

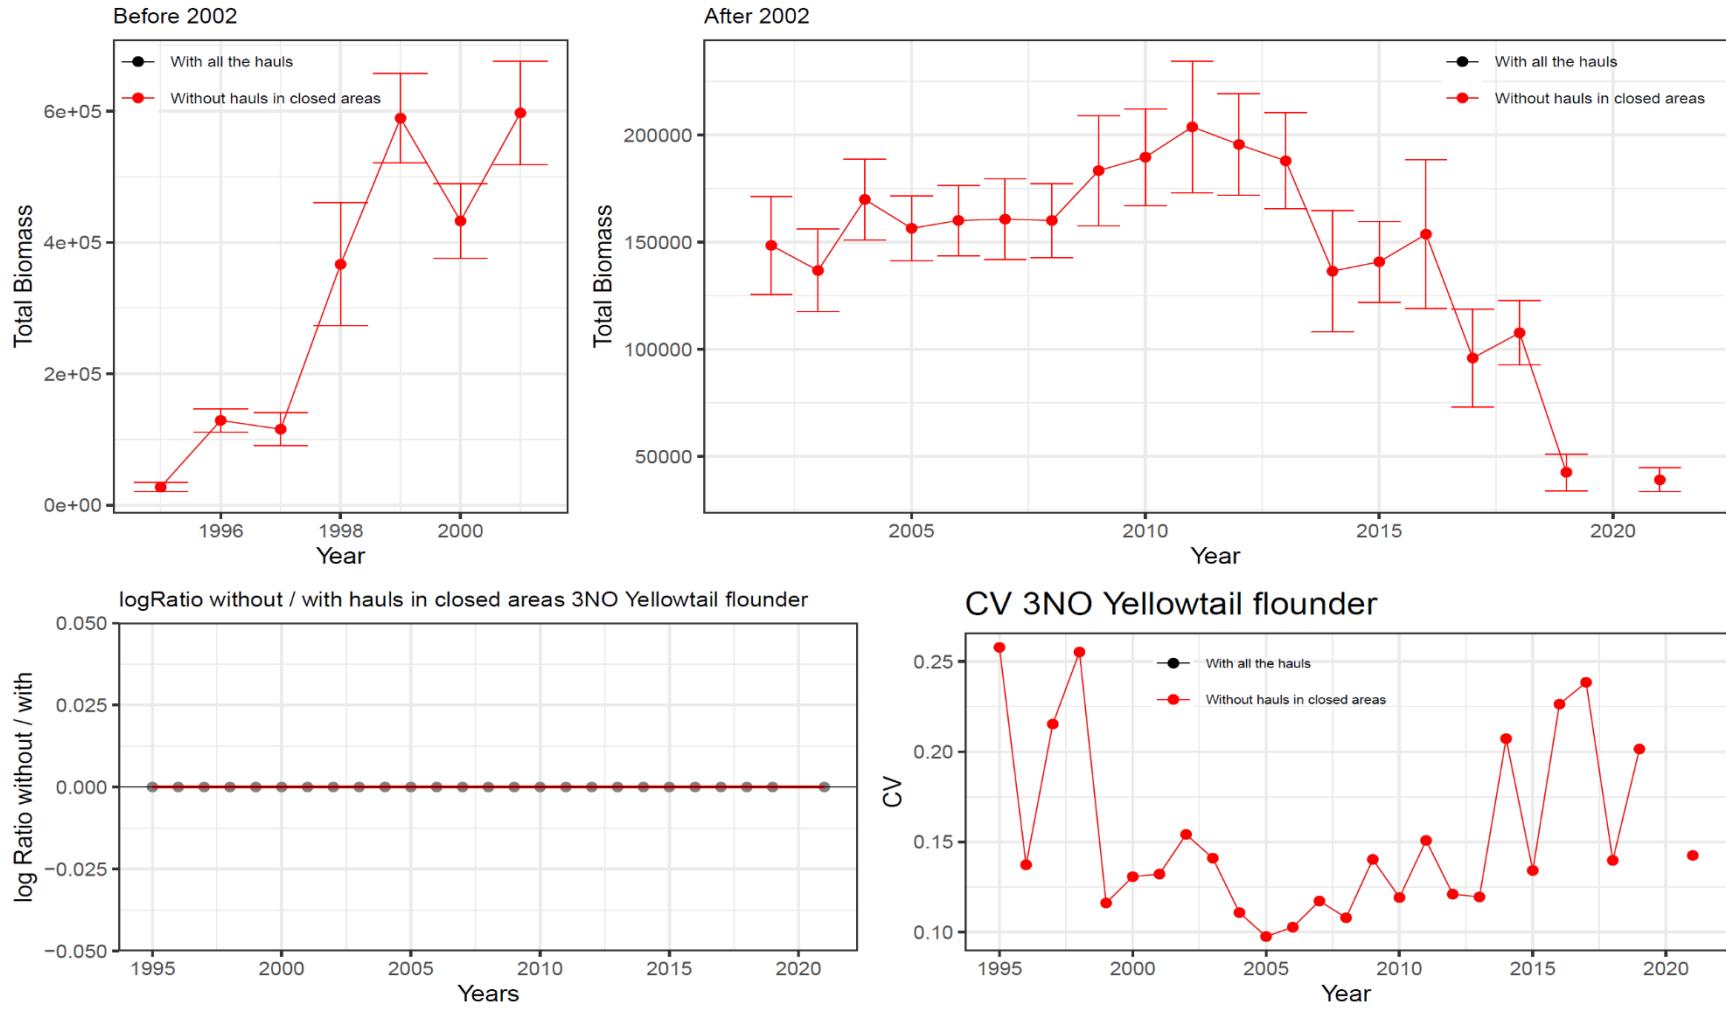

Figure 25. Biomass and SD by year (1995-2021) of the yellowtail flounder in 3NO with and without the closed areas. Top plot: total biomass by year. Bottom left plot: log-ratio plot (indicating the relative bias caused by removing data from the protected areas and the GAM smoother trend line and 95% confidence intervals). Bottom right plot: CV of the biomass (SD/biomass).

Biomass 3NO Capelin

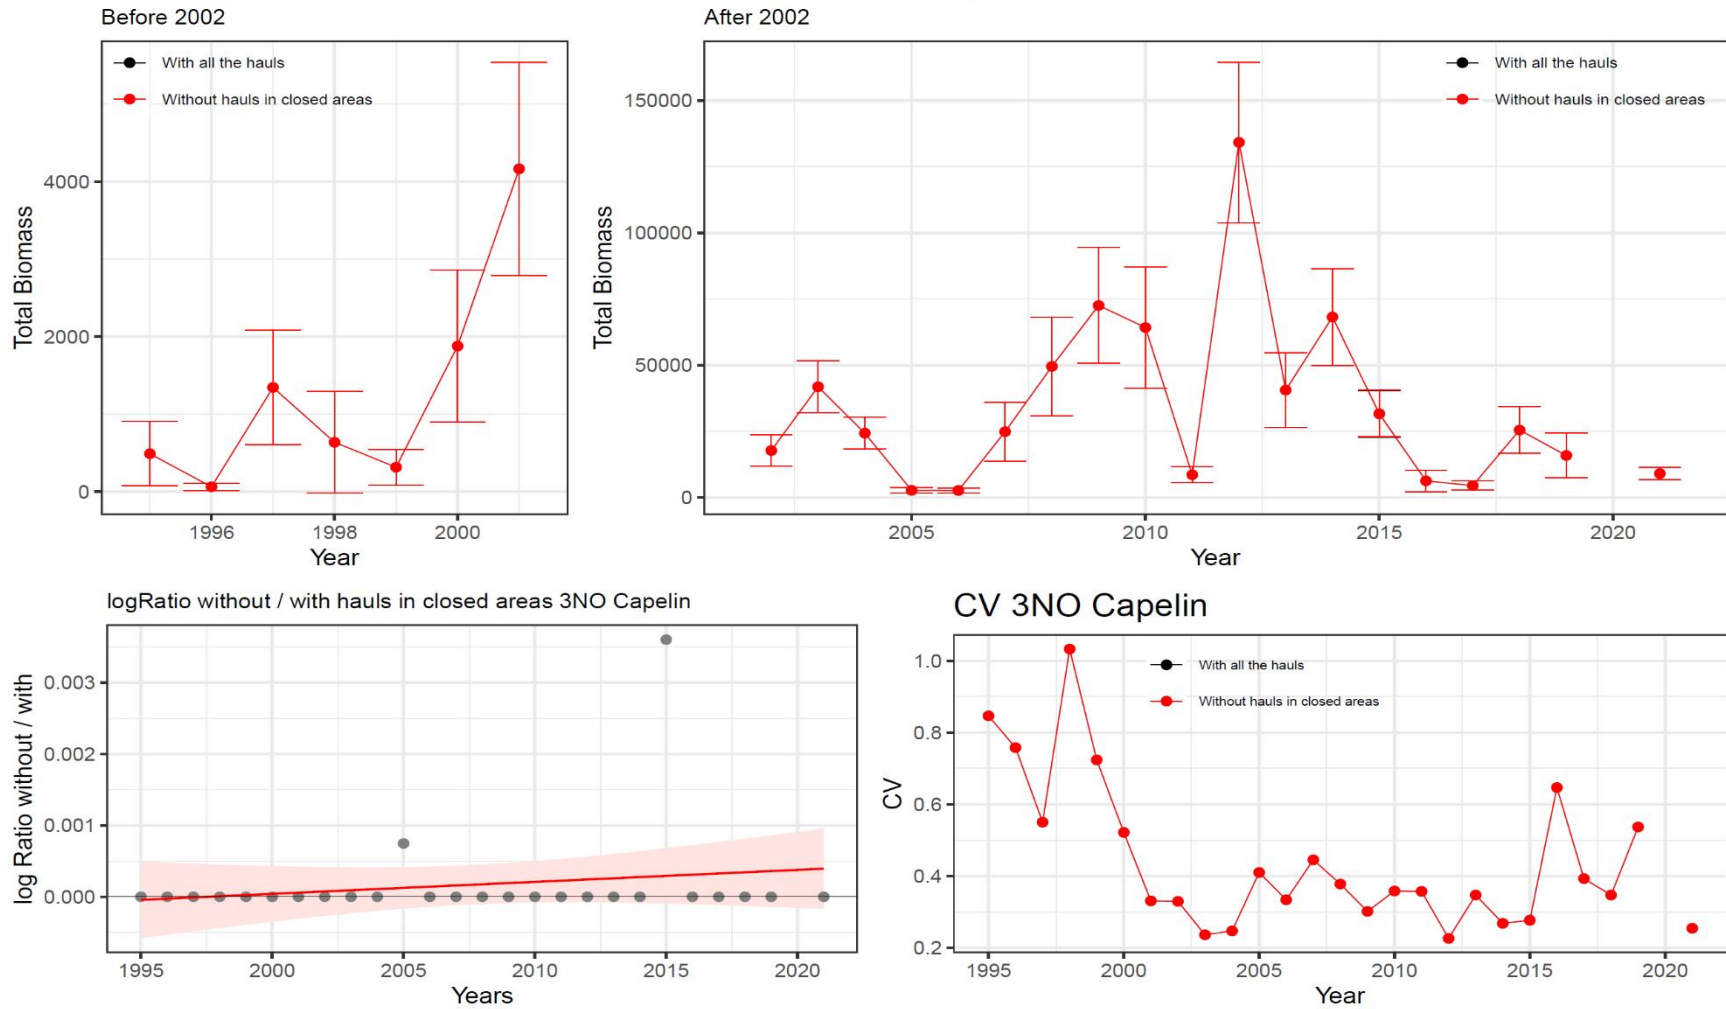

Figure 26. Biomass and SD by year (1995-2021) of the capelin in 3NO with and without the closed areas. Top plot: total biomass by year. Bottom left plot: log-ratio plot (indicating the relative bias caused by removing data from the protected areas and the GAM smoother trend line and 95% confidence intervals). Bottom right plot: CV of the biomass (SD/biomass).

Biomass 3NO Thorny skate

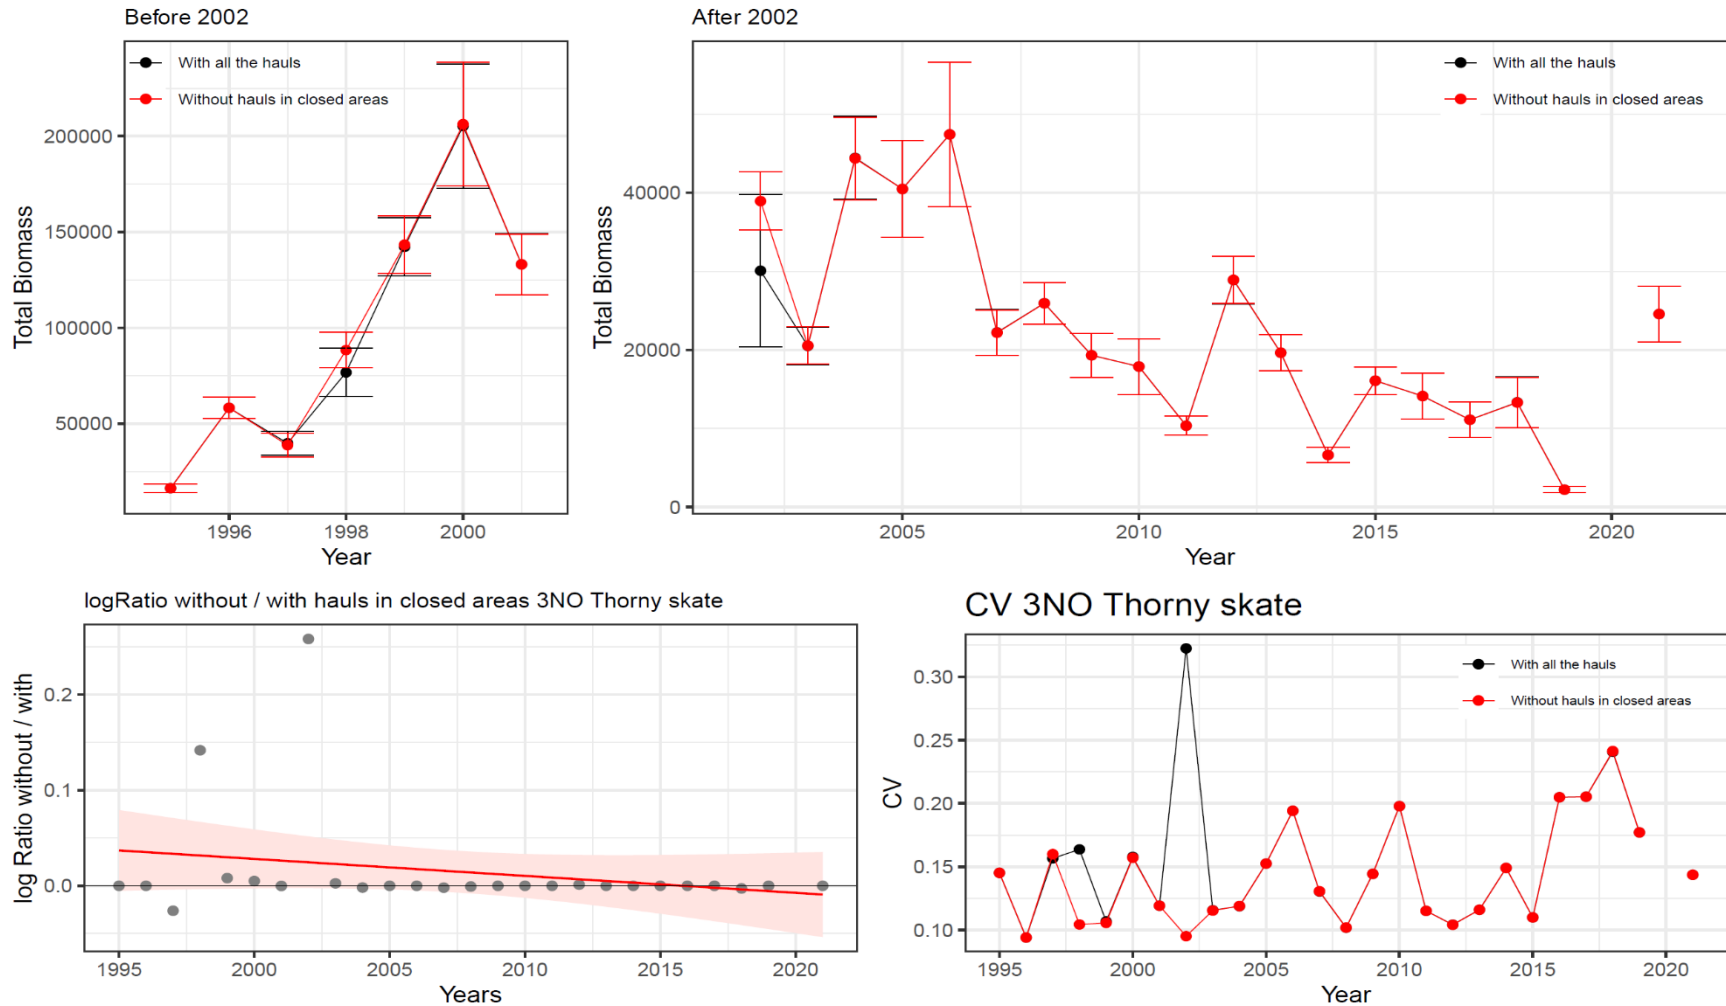

Figure 27. Biomass and SD by year (1995-2021) of the thorny skate in 3NO with and without the closed areas. Top plot: total biomass by year. Bottom left plot: log-ratio plot (indicating the relative bias caused by removing data from the protected areas and the GAM smoother trend line and 95% confidence intervals). Bottom right plot: CV of the biomass (SD/biomass).

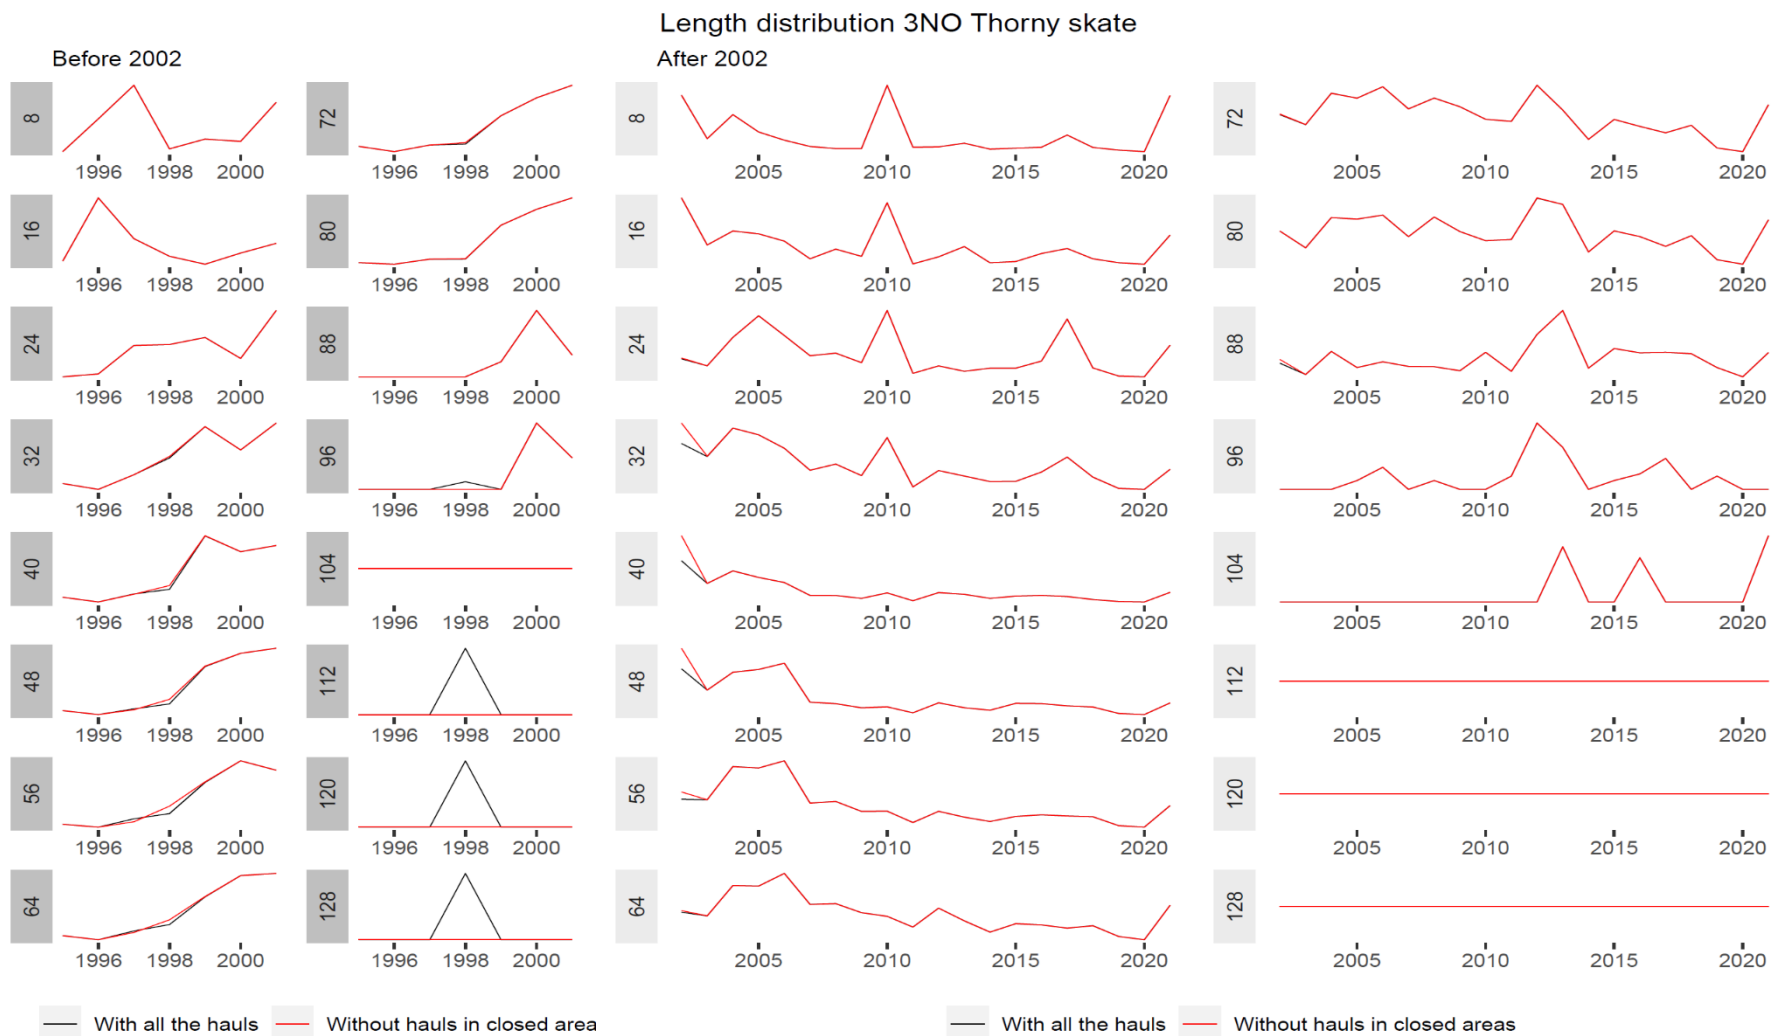

Figure 28. Length distribution by year (1995-2021) of the thorny skate in 3NO with and without the closed areas.

Biomass 3NO White hake

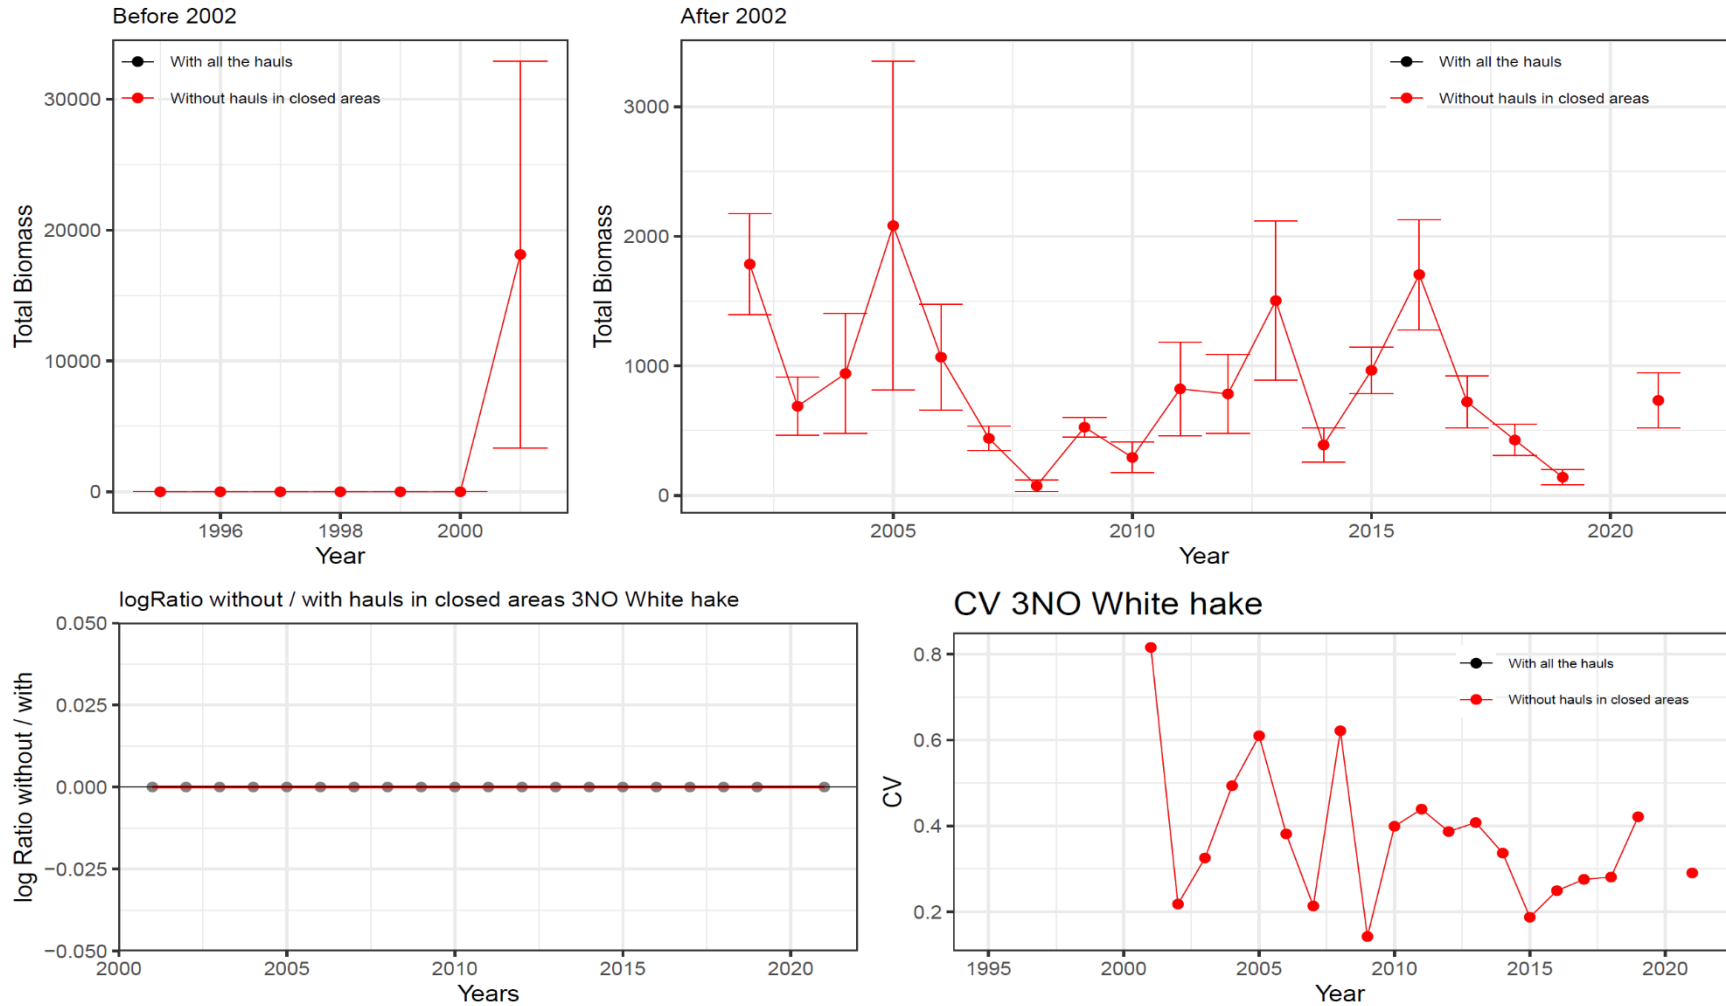

Figure 29. Biomass and SD by year (1995-2021) of the white hake in 3NO with and without the closed areas. Top plot: total biomass by year. Bottom left plot: log-ratio plot (indicating the relative bias caused by removing data from the protected areas and the GAM smoother trend line and 95% confidence intervals). Bottom right plot: CV of the biomass (SD/biomass).

Biomass 3NO Squid

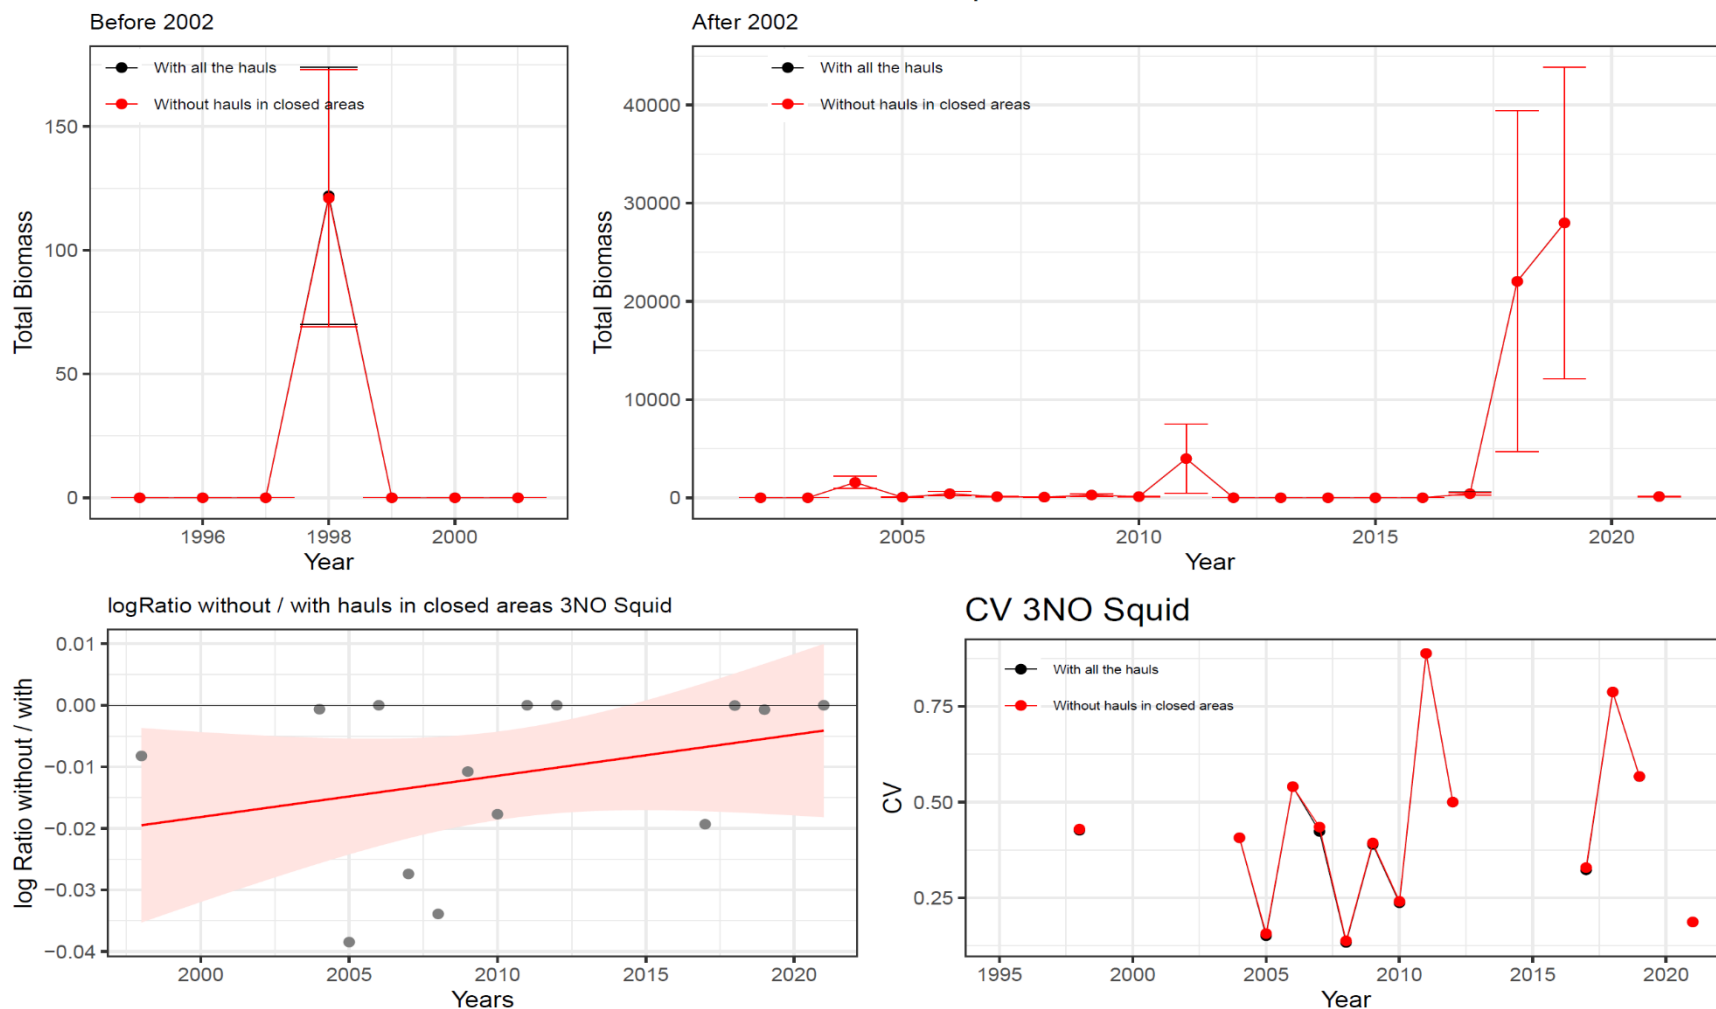

Figure 30. Biomass and SD by year (1995-2021) of the squid in 3NO with and without the closed areas. Top plot: total biomass by year. Bottom left plot: log-ratio plot (indicating the relative bias caused by removing data from the protected areas and the GAM smoother trend line and 95% confidence intervals). Bottom right plot: CV of the biomass (SD/biomass).

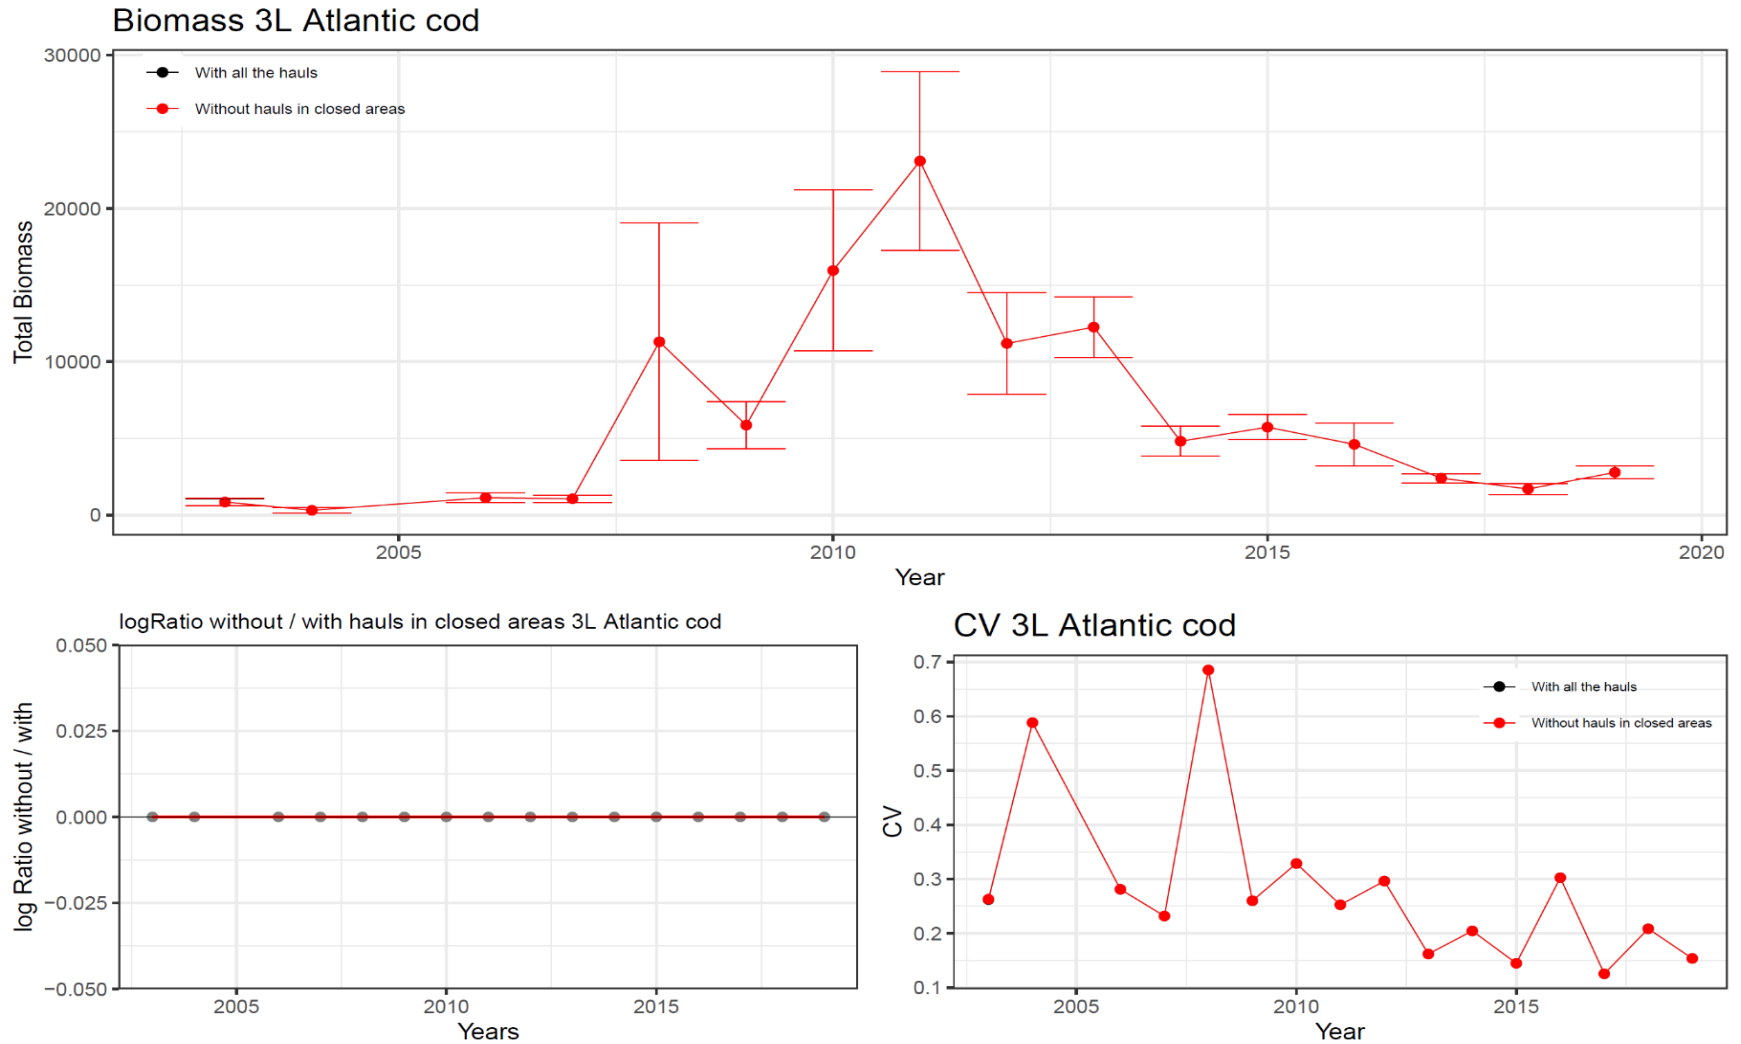

Figure 31. Biomass and SD by year (2003-2019) of the Atlantic cod in 3L with and without the closed areas. Top plot: total biomass by year. Bottom left plot: log-ratio plot (indicating the relative bias caused by removing data from the protected areas and the GAM smoother trend line and 95% confidence intervals). Bottom right plot: CV of the biomass (SD/biomass).

Biomass 3L Greenland halibut

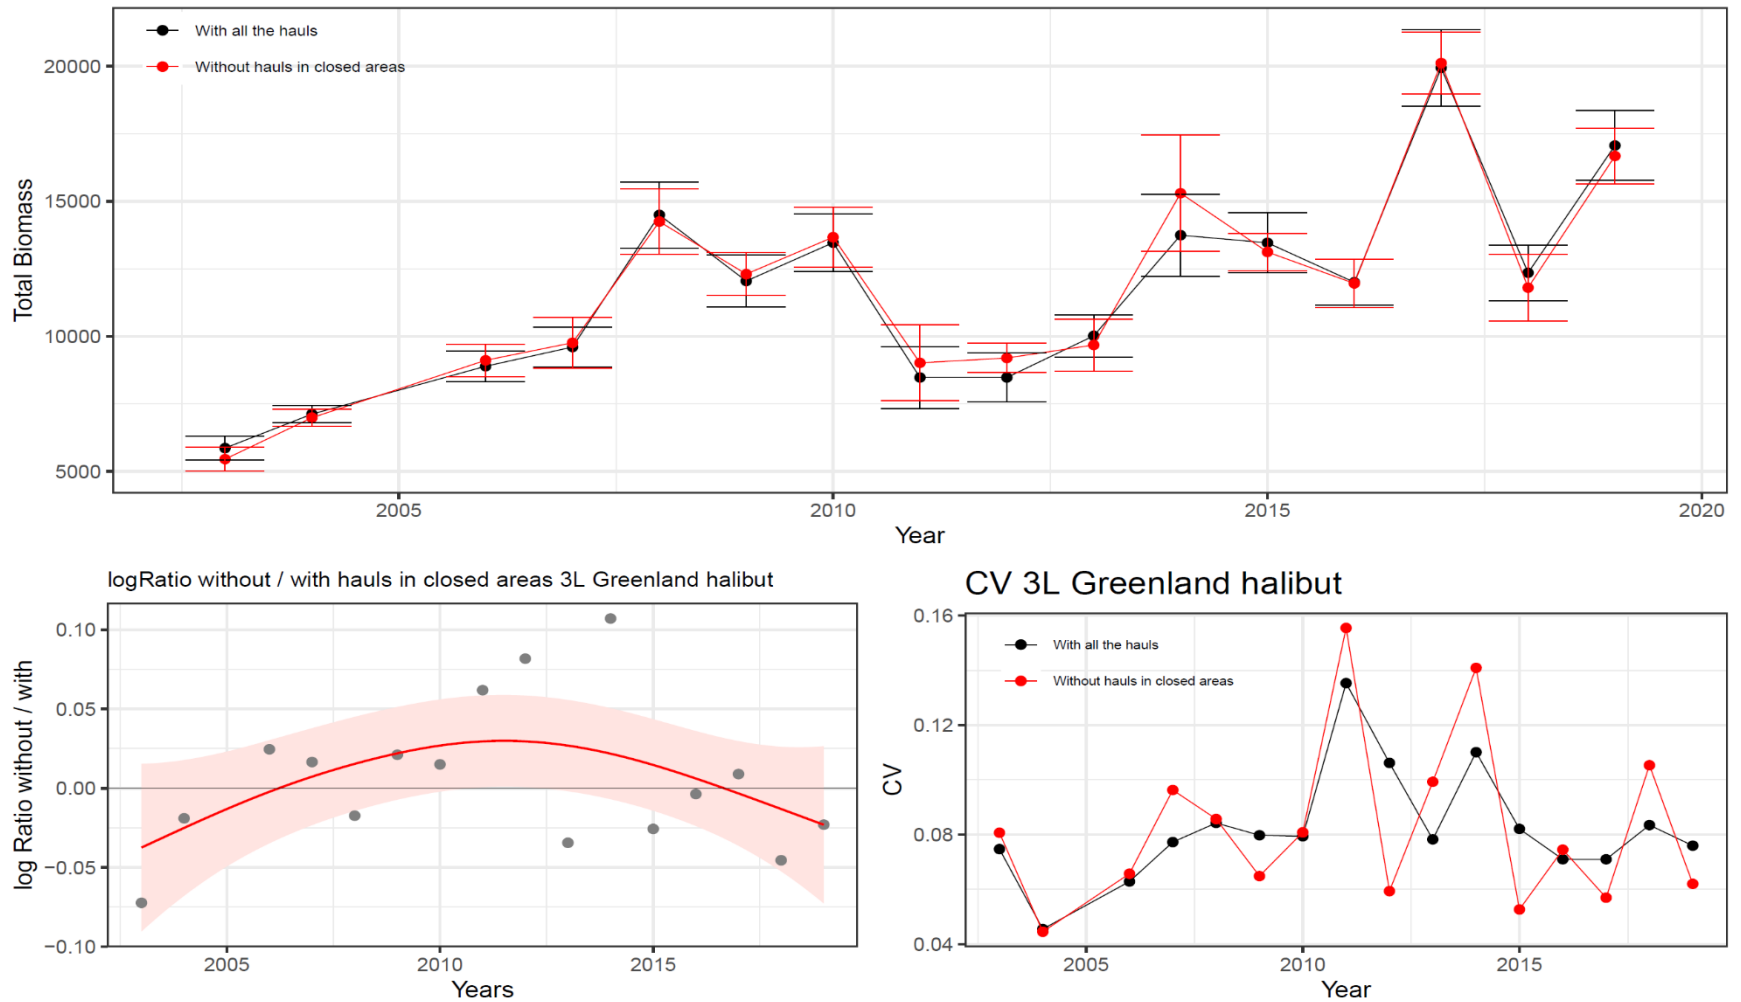

Figure 32. Biomass and SD by year (2003-2019) of the Greenland halibut in 3L with and without the closed areas. Top plot: total biomass by year. Bottom left plot: log-ratio plot (indicating the relative bias caused by removing data from the protected areas and the GAM smoother trend line and 95% confidence intervals). Bottom right plot: CV of the biomass (SD/biomass).

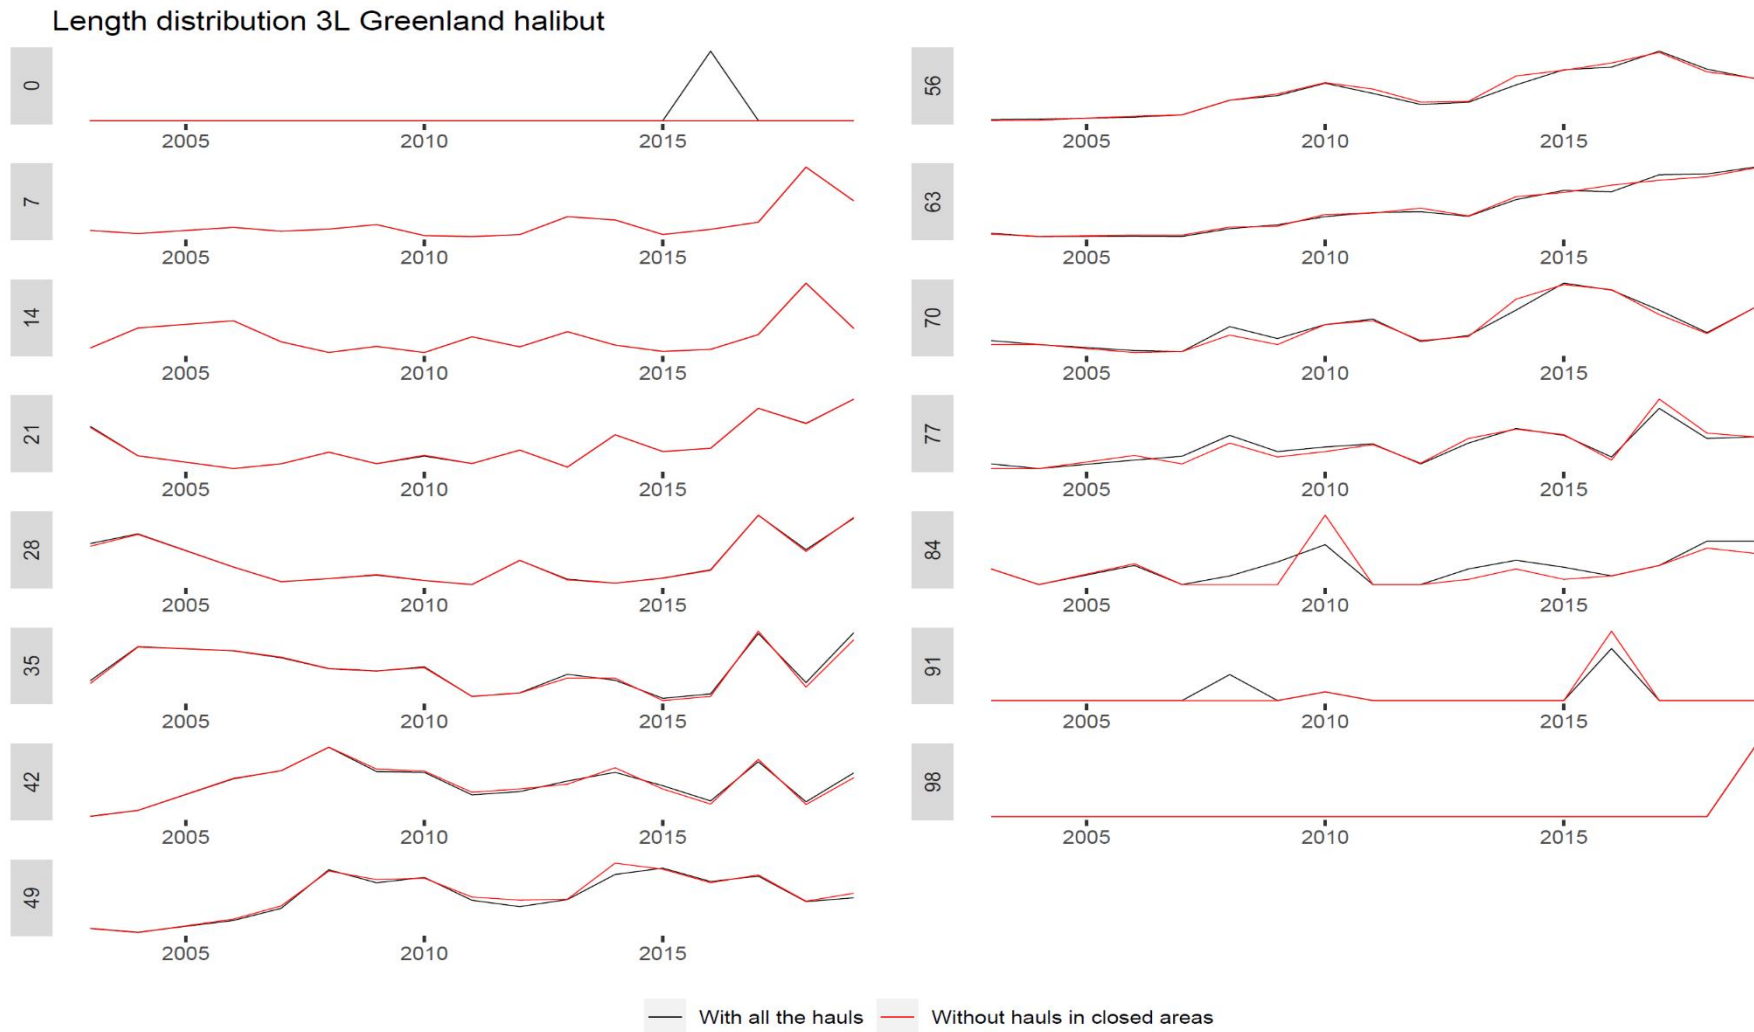

Figure 33. Length distribution by year (2003-2019) of the Greenland halibut in 3L with and without the closed areas.

Biomass 3L American plaice

Figure 34. Biomass and SD by year (2003-2019) of the American plaice in 3L with and without the closed areas. Top plot: total biomass by year. Bottom left plot: log-ratio plot (indicating the relative bias caused by removing data from the protected areas and the GAM smoother trend line and 95% confidence intervals). Bottom right plot: CV of the biomass (SD/biomass).

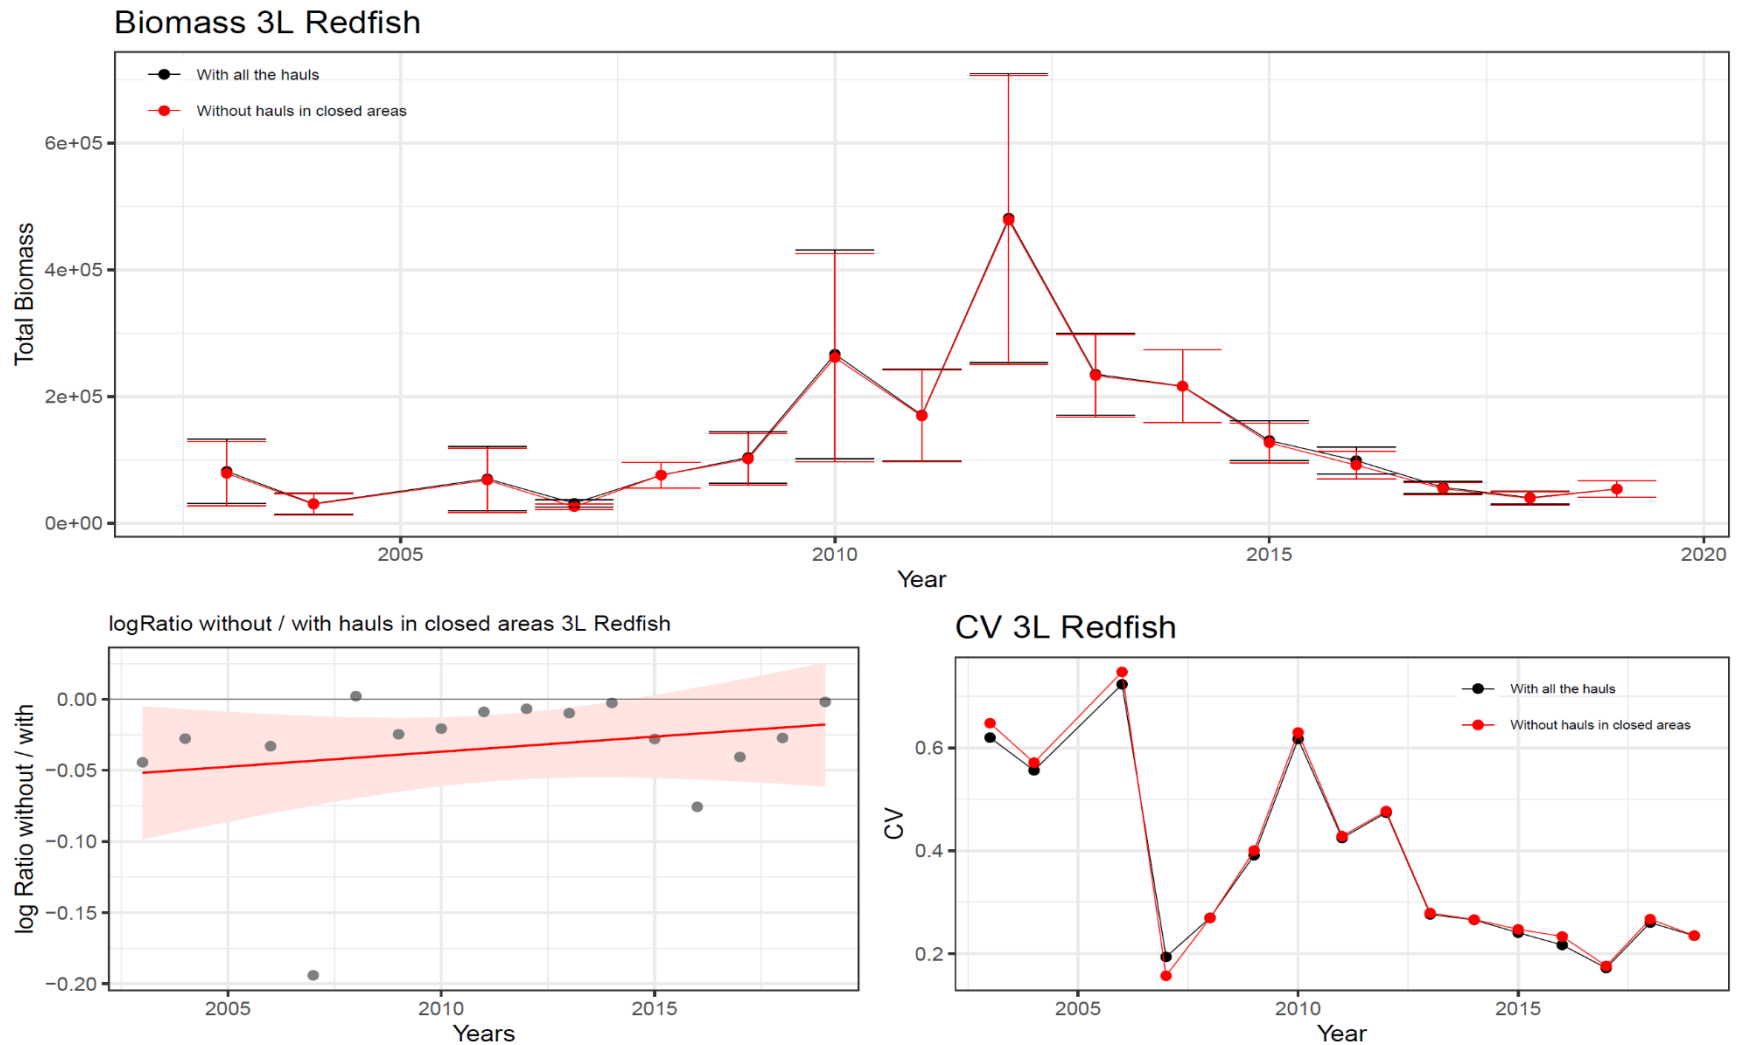

Figure 35. Biomass and SD by year (2003-2019) of the redfish in 3L with and without the closed areas. Top plot: total biomass by year. Bottom left plot: log-ratio plot (indicating the relative bias caused by removing data from the protected areas and the GAM smoother trend line and 95% confidence intervals). Bottom right plot: CV of the biomass (SD/biomass).

Figure 36. Length distribution by year (2003-2020) of the redfish in 3L with and without the closed areas.

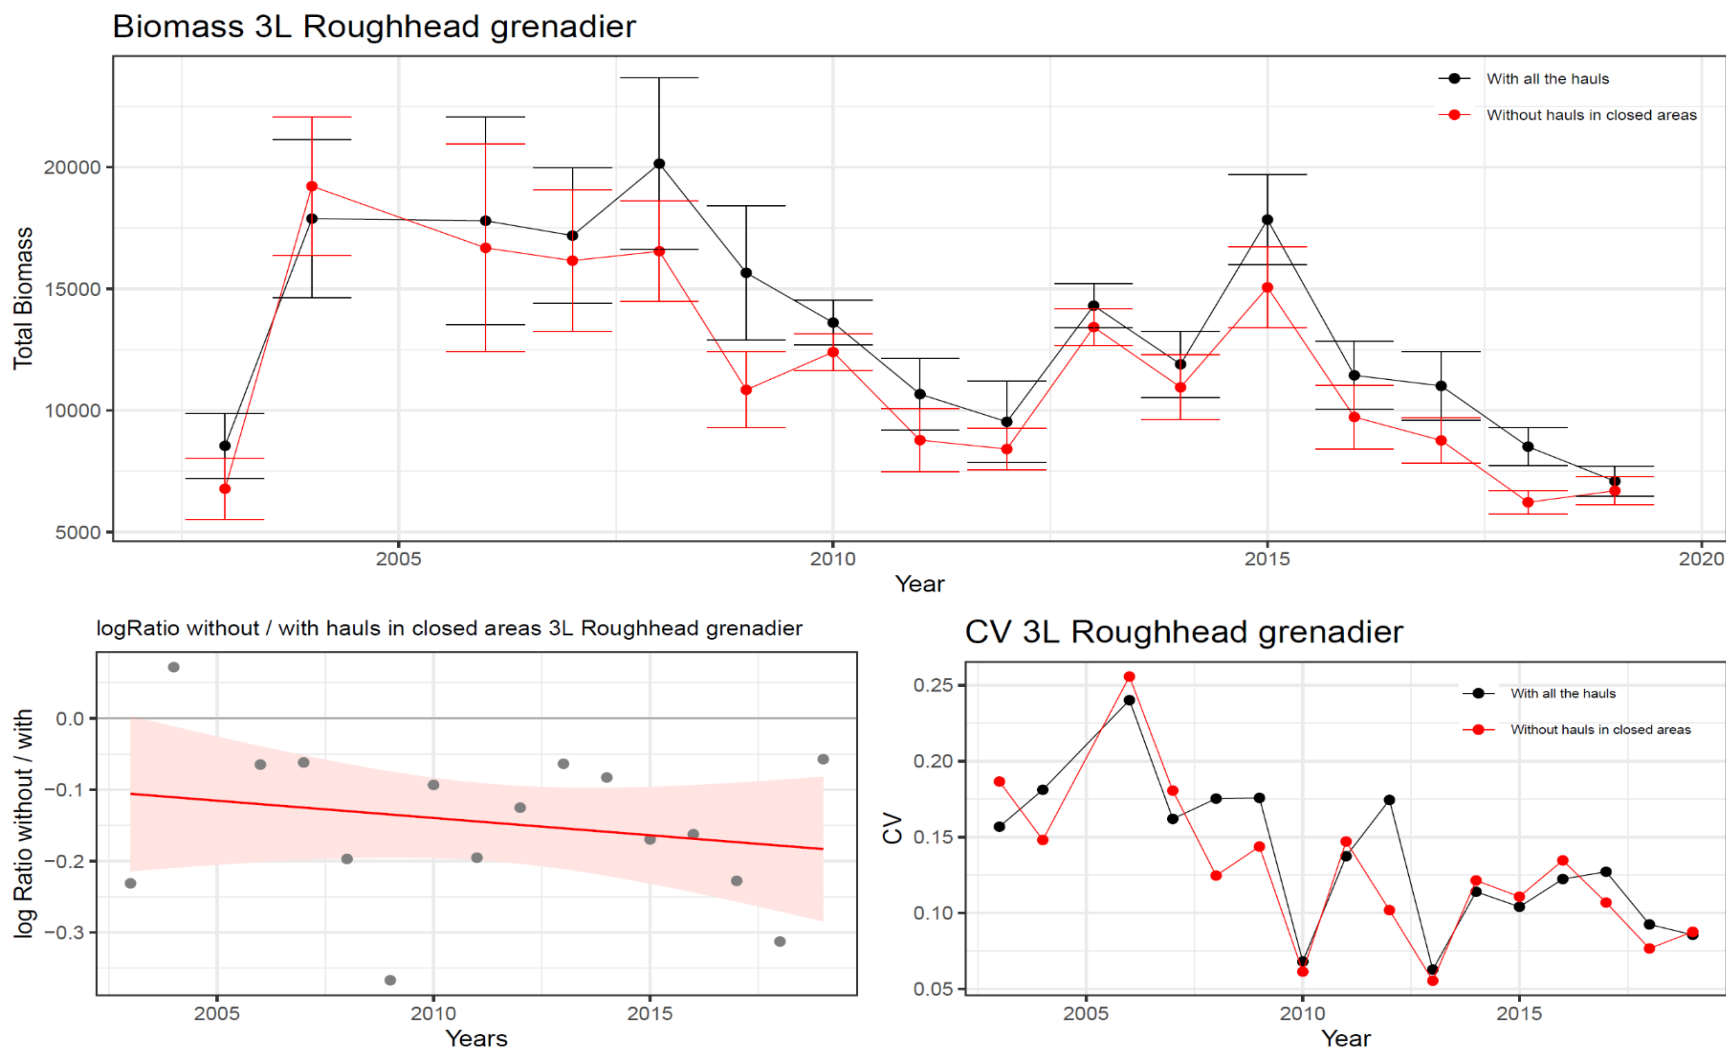

Figure 37. Biomass and SD by year (2003-2019) of the roughhead grenadier in 3L with and without the closed areas. Top plot: total biomass by year. Bottom left plot: log-ratio plot (indicating the relative bias caused by removing data from the protected areas and the GAM smoother trend line and 95% confidence intervals). Bottom right plot: CV of the biomass (SD/biomass).

Figure 38. Length distribution by year (2003-2020) of the roughhead grenadier in 3L with and without the closed areas.

Biomass 3L Witch flounder

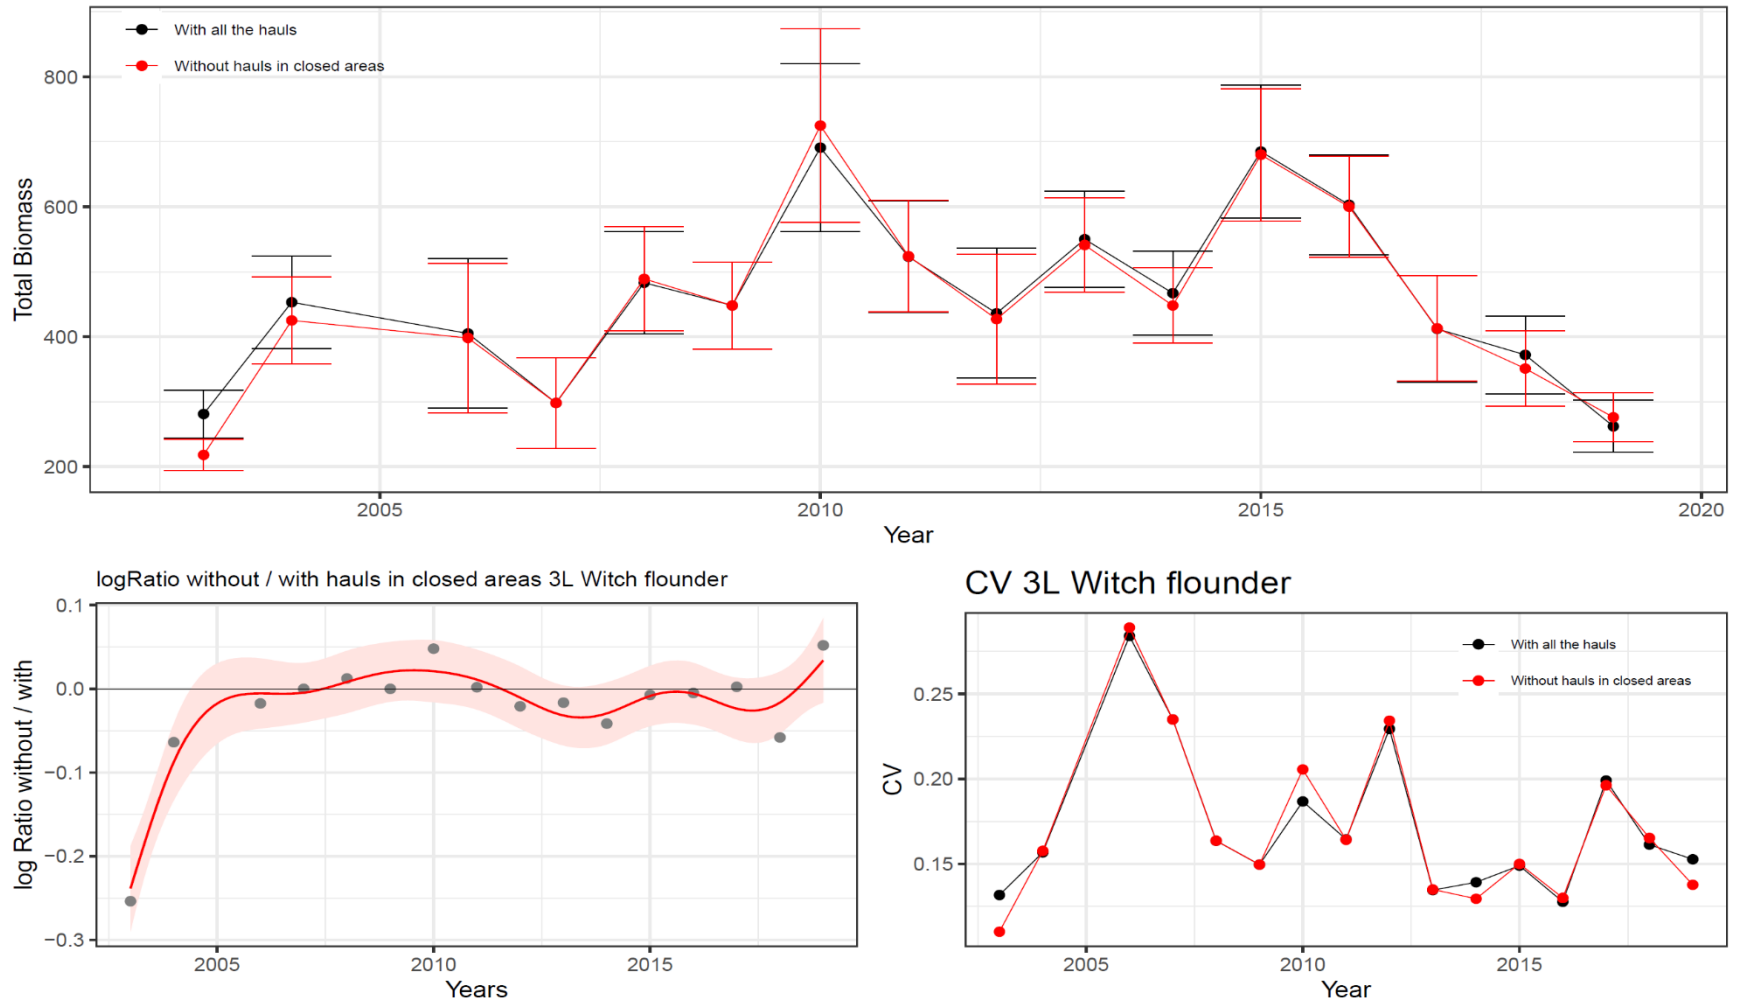

Figure 39. Biomass and SD by year (2003-2019) of the witch flounder in 3L with and without the closed areas. Top plot: total biomass by year. Bottom left plot: log-ratio plot (indicating the relative bias caused by removing data from the protected areas and the GAM smoother trend line and 95% confidence intervals). Bottom right plot: CV of the biomass (SD/biomass).

Figure 40. Length distribution by year (2003-2020) of the witch flounder in 3L with and without the closed areas.

Biomass 3L Thorny skate

logRatio without / with hauls in closed areas 3L Thorny skate

CV 3L Thorny skate

Figure 41. Biomass and SD by year (2003-2019) of the thorny skate in 3L with and without the closed areas. Top plot: total biomass by year. Bottom left plot: log-ratio plot (indicating the relative bias caused by removing data from the protected areas and the GAM smoother trend line and 95% confidence intervals). Bottom right plot: CV of the biomass (SD/biomass).
